some dissolved nitrogen peroxide which gives it a yellowish red colour. It may be purified by redistillation over barium and silver nitrates and then under diminished pressure over urea. On the large scale it is obtained by three methods: (1) from saltpetre and concentrated sulphuric acid; (2) by the catalytic oxidation of ammonia; and (3) by the direct oxidation of nitrogen in the electric arc. In the first and oldest method, Chile saltpetre is distilled with concentrated sulphuric acid in horizontal cast iron stills, the vapours being condensed in a series of stoneware Woulfe's bottles. In practice the theoretical quantity of acid and Chile saltpetre is not used, but the charge is so regulated that the mixture of acid and neutral sodium sulphate formed in the retort remains liquid at the temperature employed, and consequently can be readily removed. (2) The oxidation of ammonia is effected by passing this gas mixed with air or oxygen over a thin coating of spongy platinum deposited on a supporting material and kept at about 600°C . Platinum gauze may replace the sponge, and the gases may be pre-heated at $300\text{--}400^\circ\text{C}$, the heat of reaction then being sufficient to maintain the whole at the required higher temperature. Other catalysts may be used and each has an appropriate suitable temperature; thus, with iron oxide the best temperature is $650\text{--}700^\circ$. Often a mixture of oxides is more efficient, one acting as a "promoter" for the other. The ammonia must be free from impurities such as phosphine, and a fairly rapid stream of gas is used. The yields may exceed 95% of the theoretical. (3) For the production of nitric acid from air see NITROGEN, FIXATION OF. Fuming nitric acid consists of a solution of nitrogen peroxide in concentrated nitric acid and is prepared by distilling dry sodium nitrate with concentrated sulphuric acid.

Nitric acid is a colourless strongly fuming liquid, having a specific gravity of 1.50394 (24.2°C) (V. Veley 1898). It is exceedingly hygroscopic and corrosive. On distillation, the pure acid begins to boil at 78.2°C (W. Ramsay), partial decomposition into water, oxygen and nitrogen peroxide taking place. The acid solidifies when strongly cooled, the solid melting at -47°C . Concentrated nitric acid forms with water a constant-boiling mixture, the composition of which varies according to the pressure at which it is distilled: if distillation is at atmospheric pressure, the resulting acid boils at 120.5°C , contains 68% of HNO_3 and possesses a specific gravity of 1.414 (15.5°C). If a more dilute acid than this be distilled, water passes over in excess and the residue in the retort reaches the above composition and boiling point; on distillation of a stronger acid, excess of HNO_3 passes into the distillate and the boiling point rises until the values of the constant-boiling mixture are reached. On the hydrates of nitric acid see V. Veley, *Jour. Chem. Soc.*, 1903, 83, p. 1015, and F. W. Kuster, *Zeit. anorg. Chem.*, 1904, 41, p. 1. On mixing nitric acid with water there is a rise of temperature and a contraction in volume.

The acid is a powerful oxidizing agent. It attacks most metals readily, usually with production of a nitrate or hydrated oxide of the metal and one or other of the oxides of nitrogen, or occasionally with the production of ammonium salts; magnesium, however, liberates hydrogen from the very dilute acid. Its action on metals depends in most cases on the temperature, strength of the acid, and the nature of the products of reaction. Thus in the case of copper, it is found that the diluted acid acts very slowly upon the metal at first, but as the reaction proceeds the copper dissolves more rapidly up to a certain point and then the rate of solution again diminishes. This is possibly due to the accelerating action of the nitrous acid which is produced in the direct action of the copper on the nitric acid and which, when a certain amount has been formed in the system, begins to decompose, thus

Iron when brought into contact with nitric acid under certain conditions, remains passive to the acid. Thus at 55°C it is passive to an acid of specific gravity 1.42 and at 31°C to an acid of specific gravity 1.38. The cause of this passivity was for long a matter of dispute, but V. R. Evans in 1927 (*J. Chem. Soc.*, p. 1020) succeeded in isolating an actual protective film from passivated iron. Nitric acid is without action on gold, platinum, iridium and rhodium.

A. Hantzsch (*Berichte*, 1925, 55, p. 941) believes that con-

concentrated nitric acid is chiefly composed of "nitronium" nitrate, $[N(OH)_2](NO_3)_2$. (See also ACIDS.)

The salts of nitric acid, known as *nitrates*, are nearly all readily soluble in water and crystallize well. They are all decomposed when heated to a sufficiently high temperature, with evolution for the most part of oxygen and nitrogen peroxide, leaving a residue of oxide of the metal. They may be recognized by the fact that on the addition of a solution of ferrous sulphate, followed by that of concentrated sulphuric acid (the mixture being kept quite cold), the ferrous sulphate solution becomes of a deep brown colour, owing to the reducing action of the ferrous sulphate on the nitric acid which is liberated by the action of the sulphuric acid on the nitrate. As an alternative method the nitrate may be warmed with some fragments of copper and sulphuric acid which has been diluted with its own volume of water, when characteristic brown vapours will be seen.

Nitric acid finds extensive application in the manufacture of sulphuric acid, certain coal-tar colouring matters, explosives, and in the production of various nitrates.

In medicine, nitric acid is used externally in a pure state as a caustic to destroy chancres, warts and phagadenic ulcers, and diluted preparations are employed in the treatment of dyspepsia, etc. Poisoning by strong nitric acid produces a widespread gastro-enteritis, burning pain in the oesophagus and abdomen and bloody diarrhoea. There may also be blood in the urine. Death occurs from collapse or from secondary destructive changes in the intestinal canal. Characteristic yellow staining of the skin round the mouth from the formation of xanthoproteic acid serves to distinguish it from poisoning by other acids. The antidotes are mild alkalis, together with the use of opium to relieve pain.

(See A. Cottrell, *The Manufacture of Nitric Acid and Nitrates*, London, 1923.)

NITROBENZENE, the simplest aromatic nitro-compound, $C_6H_5NO_2$, was first isolated in 1834 by E. Mitscherlich, and is prepared commercially by the gradual addition of benzene to a well-cooled mixture of concentrated nitric and sulphuric acids, the oily product being separated, washed with alkali, and then distilled. It is a yellowish liquid possessing a strong smell of oil of bitter almonds. It boils at $209^\circ C$, and melts at $5.7^\circ C$. The products of its electrolytic reduction vary with the conditions: in sulphuric acid solution it yields para-aminophenol (L. Gattermann, 1893); in alcoholic alkaline solution it yields azoxybenzene; in acid alcoholic solution, benzidine; in ammoniacal alcoholic solution, phenylhydrazine. With chlorine, in the presence of iodine or antimony chloride, it yields meta-chloronitrobenzene. It occasionally acts as an oxidizing agent, as in the preparation of quinoline and fuchsine (magenta, *q.v.*). It is used commercially for the preparation of aniline (*q.v.*) and of benzidine (*q.v.*); and in perfumery (oil of mirbane).

Dinitrobenzenes, $C_6H_4(NO_2)_2$.—Ortho-dinitrobenzene, produced in small quantity in the preparation of meta-dinitrobenzene, forms colourless crystals which melt at $116.5^\circ C$ and boil at $319^\circ C$ (773 mm.). When boiled with aqueous caustic soda, it yields ortho-nitrophenol. Meta-dinitrobenzene is formed by the direct nitration of nitrobenzene with fuming nitric acid, the product being poured into water and recrystallized from dilute alcohol. It forms practically colourless needles which melt at $89.7^\circ C$, and boil at $302.8^\circ C$. It is used for the preparation of meta-phenylenediamine. Para-dinitrobenzene results from the action of nitrogen peroxide on an ethereal solution of quinone dioxime; it crystallizes in colourless needles, which melt at $171-172^\circ C$.

Trinitrobenzenes, $C_6H_3(NO_2)_3$.—Asymmetrical (1:2:4) trinitrobenzene results from the action of fuming nitric and sulphuric acids on para-dinitrobenzene. It forms yellow crystals, which melt at $57.5^\circ C$. When boiled with dilute aqueous caustic soda it yields 2:4-dinitrophenol. Symmetrical (1:3:5) trinitrobenzene is formed by the further nitration of meta-dinitrobenzene with fuming sulphuric and nitric acids; or by the action of water on 2:4:6-trinitrobenzoic acid (German patent 77,353). It crystallizes in prisms which melt at $121^\circ C$.

NITRO-CELLULOSE POWDER: see GUN COTTON.

NITRO-CELLULOSE SILK: see SILK, ARTIFICIAL.

NITRO-COMPOUNDS, in organic chemistry, compounds containing the univalent radical NO_2 directly combined with carbon.

Aromatic Nitro-compounds.—The most important nitro-com-

pounds are those of the aromatic series derived from benzene, toluene, xylene and naphthalene, since they find extensive use either in the manufacture of synthetic dyes (*q.v.*) or in the production of high explosives. (See articles under EXPLOSIVES and T.N.T.) These aromatic nitro-compounds are manufactured by the direct action of nitric acid on the hydrocarbon, this reaction being generally carried out in the presence of concentrated sulphuric acid which absorbs the water formed during nitration. In this way benzene can be nitrated in three stages to furnish nitrobenzene (*q.v.*), 1:3-dinitrobenzene and 1:3:5-trinitrobenzene. Toluene gives rise to *ortho*- and *para*-nitrotoluene with a small amount of *meta*-nitrotoluene. (See CHEMISTRY: Organic.) These three isomeric nitro-toluenes undergo further nitration yielding various di- and tri-nitrotoluenes. Of these higher nitration products the most important is 2:4:6-trinitrotoluene or T.N.T.

Naphthalene on nitration yields almost exclusively α -nitro-naphthalene, and energetic nitration of this product gives 1:5- and 1:8-dinitronaphthalenes. These dinitro-compounds and their higher nitration products have been utilised in explosives. (See also NAPHTHALENE.)

Nitrobenzene (*q.v.*) and *ortho*-nitrotoluene (m.p. $10.5^\circ C$, b.p. $218^\circ C$) are pale yellow oils distilling without decomposition and having characteristic odours (artificial oil of mirbane) recalling that of oil of bitter almonds. *Para*-nitrotoluene melts at $54^\circ C$ and boils at $230^\circ C$.

These nitro-compounds yield on reduction in acid media the aromatic amines, nitrobenzene giving aniline and the nitrotoluenes furnishing the corresponding toluidines. In alkaline media the reduction leads successively to azoxy-, azo- and hydrazo-compounds. Thus nitrobenzene passes successively into azoxybenzene, azobenzene and hydrazobenzene. The last of these on treatment with acid changes into benzidine (*q.v.*). This series of chemical changes constitutes an important use for nitrobenzene, and in a similar manner *ortho*-nitrotoluene is employed in the manufacture of tolidine, a valuable colour intermediate.

The aromatic dinitro-compounds are also reducible to aromatic bases, 1:3-dinitrobenzene giving *metaphenylenediamine*, and 2:4-dinitrotoluene giving 2:4-tolylenediamine. Both these diamines are used in colour making. The partial reduction of 1:3-dinitrobenzene with sodium disulphide gives *metanitroaniline*, $NO_2 \cdot C_6H_4 \cdot NH_2$, this base being useful in the colour industry and also in the production of an exceptionally powerful high explosive, tetranitroaniline or T.N.A., $C_6H(NO_2)_4 \cdot NH_2$. Nitrobenzene reduced in neutral solution furnishes β -phenylhydroxylamine, and this is readily transformed to *para*-aminophenol, which is both a colour intermediate and a photographic developer ("Rodinal").

The aromatic nitro-compounds are employed as oxidising agents. Nitrobenzene or *ortho*-nitrotoluene is employed with a ferrous chloride catalyst to oxidise a mixture of aniline and toluidine in the manufacture of magenta. Nitrobenzene and its homologues are also used as the oxidising agent in the Skraup reaction for quinoline and allied bases.

Aliphatic Nitro-compounds (Nitro-paraffins).—In this series the nitro-group is attached directly to an alkyl radical. These aliphatic nitro-compounds are chiefly of academic interest but they are also useful in the diagnosis of the various types of alcohols (*q.v.*). They are prepared by the action of alkyl iodides on silver nitrite (V. Meyer, 1874). They are also produced by the action of sodium nitrite on the α -halogenated fatty acids; the α -nitro-fatty acids first formed readily lose carbon dioxide and yield the nitro-paraffin (H. Kolbe, 1872).

Among the higher paraffins, for example normal hexane and octane, nitro-paraffins are obtainable by direct nitration as in the aromatic series (M. Konowalow, 1892; R. A. Worstall, 1898). The nitro-paraffins are colourless, fragrant liquids distilling without decomposition. Primary and secondary aliphatic nitro-compounds containing respectively the groups $\cdot CH_2NO_2$ and $>CH \cdot NO_2$ form metallic derivatives, for example sodium salts, which according to A. Hantzsch are derived from the isomeric *iso*-nitro-compounds, $R \cdot NO \cdot OH$. This variety is the truly acidic form and the ordinary primary and secondary nitro-paraffins are

to be regarded as *pseudo*-acids. The reactions of the nitro-paraffins with nitrous acid are characteristic and utilisable in discriminating between primary, secondary and tertiary alcohols (V. Meyer, 1875). The alcohols are converted successively into iodides and nitro-paraffins. The primary paraffin yields a colourless *nitrolic acid*, $R\cdot C(NO\cdot)NO$, which forms a red alkali salt; the secondary paraffin gives a blue *pseudonitrole*, $RR'C(NO_2)\cdot NO$, whereas the tertiary nitro-paraffin, $RR'R''\cdot C\cdot NO_2$, is not acted on by nitrous acid and no colour effect is observed.

The nitro-paraffins are reduced by stannous chloride to β -alkylhydroxylamines and thence to aliphatic amines.

Nitromethane, $CH_3\cdot NO_2$, a colourless oil boiling at $101^\circ C$, is obtained by the action of methyl iodide on silver nitrite.

Chloropicricin, $CCl_3\cdot NO_2$, a substance employed in chemical warfare (*q.v.*), is a liquid of suffocating odour, boils at $112^\circ C$, and is obtained by the action of calcium chlorohypochlorite (chloride of lime) on picric acid.

Phenylnitromethane, $C_6H_5\cdot CH_2\cdot NO_2$, an interesting example of a nitro-compound of mixed aliphatic-aromatic type and isomeric with the nitrotoluenes (*v. supra*), prepared by the action of benzyl chloride on silver nitrite, is a colourless oily liquid boiling at 225 – $227^\circ C$ and somewhat soluble in water. It does not give a coloration with ferric chloride. It forms a sodium salt, however, from the aqueous solution of which mineral acid precipitates a solid isomeric form of phenylnitromethane melting at $84^\circ C$. This solid form gradually passes into the oily variety. The solid isomeride gives a reddish-brown coloration with ferric chloride and reacts with other reagents which serve to identify the hydroxyl group. Hence it is to be regarded as the *aci*-form of phenyl-nitromethane having the constitution $C_6H_5\cdot CH:NO\cdot OH$, and its existence affords support to Hantzsch's theory that the ordinary primary and secondary aliphatic nitro-compounds are *pseudo*-acids. (G. T. M.)

NITROGEN, is a colourless, odourless, tasteless gas, which is incombustible and does not support combustion, and is one of the most widespread and indispensable elements. Symbol N, atomic number 7, atomic weight 14.008. Its existence was first recognized by Scheele (1772) who showed that common air consists of at least two gases, which he called *foul air* and *fire air*. He obtained the foul air (nitrogen) on removal of the fire air (oxygen) by exposure to various combustible or oxidizable substances, and found that the residue would not support respiration or combustion. Lavoisier confirmed Scheele's experiments and gave to foul air the name *azote*, because of its inability to support life. The name nitrogen was introduced later by Chaptal to indicate that the element is a constituent of nitre.

Nitrogen is present in the atmosphere to the extent of approximately 78% by volume and 75.5% by weight, and serves to dilute the oxygen. It is also found in the free state in many meteorites and in volcanic gases, whilst its presence in the atmosphere of the sun and in certain stars and nebulae is revealed by the spectroscopic. Large quantities of nitrogen occur in combination with other elements, *e.g.*, in potassium nitrate (nitre or saltpetre), sodium nitrate (Chili saltpetre), ammonium salts, in rain, soil and guano, and as complex organic compounds (proteins) in all living organisms.

Preparation and Uses.—Nitrogen may be prepared (1) from the atmosphere by removal of the oxygen, or (2) from its compounds.

(1) The oxygen may be removed from air either by exposure to phosphorus in the cold (burning phosphorus is not so effective), to moist iron filings, an alkaline solution of pyrogallol, an acid solution of chromous chloride or cuprous chloride, or metallic copper in the presence of hydrochloric acid or ammonia, or by passing the air over red-hot copper.

On the large scale nitrogen is manufactured almost entirely by the fractional distillation of liquid air. Since it is more volatile than oxygen it evaporates first, and is marketed in grey cylinders under a pressure of about 120 atm. This gas contains most of the helium and neon present in the air (*see ATMOSPHERE*), but the argon is left with the oxygen. Some industrial nitrogen may be made by passing air over heated copper, the copper oxide being

afterwards reduced by heating in a current of water gas.

(2) Pure nitrogen is prepared from its compounds: (a) By heating a slightly acid solution of ammonium nitrite (or a mixture of sodium nitrite and ammonium chloride), $NH_4NO_2 = N_2 + 2H_2O$; (b) by heating ammonium dichromate, $(NH_4)_2Cr_2O_7 = Cr_2O_3 + 4H_2O + N_2$; or (c) by passing a mixture of nitric oxide and ammonia gas over red-hot copper, $6NO + 4NH_3 = 5N_2 + 6H_2O$.

Nitrogen gas is used in filling electric lamps to prevent the blackening of the bulb by volatilized metal from the filament and to enable the latter to be run at a higher temperature, but argon (*q.v.*) is superior for this purpose. High-temperature thermometers are sometimes filled with compressed nitrogen. Large quantities of nitrogen are also employed for the production of synthetic ammonia and other nitrogen compounds which are finally converted into dyes, drugs, explosives or fertilizers.

Properties.—Nitrogen gas is only slightly soluble in water, but one volume of liquid oxygen dissolves about 450 volumes of the gas. When the gas is strongly cooled under pressure, nitrogen is obtained as a colourless liquid boiling at $-195.81 \pm 0.02^\circ C$ (Henning and Heuse, 1924), at which temperature it has a specific gravity 0.8042. The critical temperature is $-147.13^\circ C$ and the critical pressure is 33.49 atm. When evaporated quickly under reduced pressure, the liquid yields a colourless solid melting at $-210.5^\circ C$ under a pressure of 86mm. The density of pure nitrogen at $0^\circ C$ and 760mm. pressure is 1.25051gm. per litre (Moles and Clavera, 1924); the mean value of a number of different workers is 1.25056gm. per litre under standard conditions ($0^\circ C$, 760mm., $g = 980.665$).

The accepted value for the atomic weight of nitrogen is 14.008 (1927, O=16); according to Aston the element has no isotopes and is an exception to the whole-number rule. Rutherford has shown that the nitrogen atom is disintegrated by the impact of swift α -particles, and hydrogen atoms are expelled from its nucleus.

Nitrogen gas is somewhat inert, but it can unite directly under certain conditions with several elements: oxygen, hydrogen, boron, silicon, tungsten, titanium, manganese, vanadium, calcium, barium, magnesium, lithium, tantalum and (probably) carbon. The compounds with metals (nitrides) are generally decomposed by water with evolution of ammonia or some other gas.

The Nitrogen Cycle.—Nitrogen is an essential constituent of animal and vegetable tissues. Animals derive the nitrogen of their tissue proteins partly from other animal proteins and partly (sometimes wholly) from plant proteins. Plants build up their proteins from inorganic nitrogen compounds in the soil and to some extent from free nitrogen in the atmosphere. Berthelot found that sterilized soils do not take up nitrogen from the air, whilst unsterilized soils do, and he concluded that assimilation is due to micro-organisms. These were found (Winogradsky, 1895; Beijerinck, 1901) to be a *Clostridium* (*C. Pasteurianum*), an-aërobic, *i.e.*, incapable of functioning in presence of oxygen unless protected by certain bacteria, and several varieties of bacteria of which the most active is *Azotobacter chroococcum*. The amount of nitrogen fixed by these bacteria increases by 30% if certain protozoa are present in the soil, although protozoa feed on bacteria.

Atmospheric nitrogen is also fixed by the co-operative action of bacteria and certain plants, chiefly *Leguminosae*, such as peas, beans and clover. The parasitic bacteria are present in small nodules on the roots of the plants, which are grown on a large scale in order to restore the nitrogen content of soils.

Large quantities of nitrogen are also fixed as oxides by electrical discharges in the atmosphere, and conveyed to the soil as nitric and nitrous acids by rain, nitrates and nitrites being formed in the soil. Altogether about 250,000 tons of nitric acid are said to be formed in this way in 24 hours. Nitrites and ammonium compounds are frequently of little use as plant foods and hence they must first be oxidized to nitrates by special soil bacteria, the process being known as "nitrification." Various other kinds of bacteria bring about denitrification in the soil and by their agency considerable quantities of gaseous nitrogen are returned to the air. The combined nitrogen content of cultivated soil is generally

enriched and renewed by means of nitrogenous fertilizers, such as nitrates and ammonium salts.

Compounds of Nitrogen and Hydrogen.—Nitrogen combines with hydrogen to form three compounds—two bases, ammonia (*q.v.*), NH_3 , and hydrazine, N_2H_4 ; and an acid, hydrazoic acid or azoimide (*q.v.*), N_3H . Secondary compounds of ammonia and hydrazine with hydrazoic acid are known, such as N_3H_4 and N_3H_6 .

Hydrazine (diamide), N_2H_4 , was originally obtained by Curtius (1887) from organic compounds containing two nitrogen atoms combined together. It is prepared commercially by a process due to Raschig (1907). Sodium hypochlorite solution is mixed with a small quantity of glue and warmed with an excess of concentrated ammonia. After addition of sulphuric acid and cooling, hydrazine sulphate, $2\text{N}_2\text{H}_4 \cdot \text{H}_2\text{SO}_4$, crystallizes out. When the sulphate is distilled under reduced pressure with concentrated potash solution, a colourless fuming liquid is obtained, called hydrazine hydrate. Anhydrous hydrazine is obtained by distilling the hydrate with solid caustic soda or barium oxide under reduced pressure. It is a colourless liquid, b.p. 113.5°C , which solidifies to white crystals, m.p. -1.4° , is poisonous, decomposes on heating ($3\text{N}_2\text{H}_4 = \text{N}_2 + 4\text{NH}_3$), and reacts violently with the halogens. In solution hydrazine acts as a weak base and forms two series of salts, *e.g.*, $\text{N}_2\text{H}_4 \cdot \text{HCl}$; $\text{N}_2\text{H}_5 \cdot 2\text{HCl}$. Hydrazine and its salts are the most powerful reducing agents known, precipitating many metals from solutions of their salts. It rapidly destroys rubber and cork and when hot attacks glass.

Hydrazoic acid, also discovered by Curtius (1890), is formed by the action of an oxidizing agent, *e.g.*, nitric acid, on hydrazine; its sodium salt is formed by passing nitrous oxide over heated sodamide, $\text{NaNH}_2 + \text{N}_2\text{O} = \text{NaN}_3 + \text{H}_2\text{O}$; when pure it is a colourless liquid (b.p. 37° , f.p. -80°) with an exceedingly irritating odour. It is very poisonous and dangerously explosive, decomposing with a blue flash on heating. The solution is strongly acid and dissolves many metals with evolution of hydrogen and ammonia, forming salts called azides. These salts, especially those of the heavy metals, are explosive, and lead azide (*q.v.*) is sometimes used as a detonator. The compounds N_3H_4 and N_3H_6 are colourless explosive crystals obtained by neutralizing hydrazoic acid with ammonia and hydrazine respectively.

Oxides of Nitrogen.—Five oxides of nitrogen are known, and the series is an excellent example of the Law of Multiple Proportions: Nitrous oxide, N_2O ; nitric oxide, NO ; nitrogen trioxide, N_2O_3 ; nitrogen peroxide, NO_2 and N_2O_4 ; nitrogen pentoxide, N_2O_5 . Nitrogen in a still higher state of oxidation exists in an unstable pernitric acid.

Nitrous oxide, N_2O , was obtained by Priestley (1772) by exposing "nitrous" air (NO) to moist iron filings. A decrease in volume occurred, and the remaining gas supported combustion better than common air. It was studied by Davy (1799), who gave it the name nitrous oxide, prepared it by the method now employed, *viz.*, by heating ammonium nitrate ($\text{NH}_4\text{NO}_3 = 2\text{H}_2\text{O} + \text{NO}_2$), and also discovered its anaesthetic properties. It is also produced by the reduction of nitric acid under certain conditions, *e.g.*, by the action of zinc on the dilute acid. Pure nitrous oxide may be obtained by mixing solutions of hydroxylamine hydrochloride and sodium nitrite in equimolecular proportions: $\text{NH}_2\text{OH} + \text{HNO}_2 = \text{N}_2\text{O} + 2\text{H}_2\text{O}$. Nitrous oxide may be synthesized from the elements under special conditions (Chapman, Goodman and Shepherd, 1926).

The gas is colourless, and has a sweetish odour and taste. Its density is 1.9777 gm. per litre, and at 15°C one volume of water dissolves 0.7778 volume of nitrous oxide. The solution, however, is neutral, showing that the gas is not the true anhydride of hyponitrous acid, $\text{H}_2\text{N}_2\text{O}_2$. It is more soluble in alcohol. Nitrous oxide supports combustion better than air because it decomposes into its elements at moderately low temperatures (beginning at 520°C) and yields a gas of which one-third by volume is oxygen. It is endothermic, that is, contains more energy than the elements from which it is formed, and can be decomposed into nitrogen and oxygen by the explosion of a detonator.

Nitrous oxide on cooling or under a pressure of 50 atm. at 15°C forms a colourless liquid, which boils at -88.7°C and on rapid

evaporation yields a white solid, m.p. -102.3°C . The critical temperature is 36.5°C and the critical pressure 71.66 atm. The chief use of nitrous oxide is as an anaesthetic for operations of short duration, but prolonged inhalation causes death. About 22 litres of the gas are required to produce insensibility and if mixed with about one-quarter of its volume of oxygen an intoxicating effect often results, hence the name "laughing gas." The decomposition of ammonium nitrate is usually employed as the manufacturing process but the temperature needs careful regulation to avoid the formation of nitrogen, ammonia and nitric oxide. One kilogram of ammonium nitrate gives 182 litres of the gas, which is purified by passage through solutions of ferrous sulphate, caustic potash and milk of lime. The product is marketed in the liquid form under pressure in steel cylinders.

Nitric oxide, NO , was probably first obtained by Van Helmont, but was first recognized as a definite gas by Priestley (1772), who prepared it by the action of dilute nitric acid on copper or mercury: $3\text{Cu} + 8\text{HNO}_3 = 3\text{Cu}(\text{NO}_3)_2 + 2\text{NO} + 4\text{H}_2\text{O}$. When prepared in this way the gas is liable to contain free nitrogen and nitrous oxide. The pure gas is obtained by dropping a mixture of potassium nitrite and potassium ferrocyanide solutions into dilute acetic acid: $\text{K}_3\text{FeC}_6\text{N}_6 + \text{KNO}_2 + 2\text{CH}_3\text{COOH} = \text{K}_3\text{FeC}_6\text{N}_6 + 2\text{CH}_3\text{COOK} + \text{H}_2\text{O} + \text{NO}$. The gas may be collected over water or, if required pure, over mercury. It is colourless and has a density of 1.3402 gm. per litre, slightly greater than that of air. At 15°C one volume of water dissolves only 0.051 volumes of the gas. It is not very easily liquefied and has a boiling point of -150.2°C and a melting point of -163.6°C . The critical temperature is -96° and the critical pressure 64 atmospheres.

Nitric oxide is the most stable oxide of nitrogen and is only dissociated into its elements to about 3.5% at $1,000^\circ\text{C}$. Consequently, burning substances will only continue to burn in the gas if they previously attain this temperature. A mixture of nitric oxide and carbon disulphide vapour burns with a brilliant lilac-coloured flame, very rich in actinic rays. Nitric oxide combines readily with oxygen to form the dioxide, NO_2 , which appears as red fumes, but a short time of contact between the gases is required for complete oxidation. The oxidation of nitric oxide is of technical importance (*see* NITROGEN, FIXATION OF) and has been the subject of a considerable amount of research. Nitric oxide is absorbed by cold ferrous sulphate solution forming a black compound, but it is readily expelled again by heating. The best absorbent for the gas is a mixture of caustic soda and sodium sulphite solutions, sodium nitroso-sulphate, $\text{Na}_2(\text{NO})_2\text{SO}_3$, being formed. Nitric oxide and all the higher oxides of nitrogen are poisonous. At the temperature of liquid oxygen, nitric oxide reacts with fluorine ($4\text{NO} + \text{F}_2 = 2\text{NO}_2\text{F} + \text{N}_2$) to form *nitryl fluoride*, the only known halide of nitric acid. It melts at -139°C and boils at -63.5°C .

Nitrogen trioxide (nitrous anhydride), N_2O_3 , was discovered by Glauber. When nitric acid (56%) is distilled with arsenious oxide or starch, and the vapours are cooled with a freezing mixture, a dark blue liquid is obtained which is crude nitrogen trioxide: $2\text{HNO}_3 + \text{As}_2\text{O}_3 = \text{As}_2\text{O}_5 + \text{H}_2\text{O} + \text{N}_2\text{O}_3$. On evaporation, the liquid decomposes almost completely into nitric oxide and nitrogen peroxide, but the two gases recombine on cooling: $\text{NO} + \text{NO}_2 \rightleftharpoons \text{N}_2\text{O}_3$. H. B. Baker has shown that when the liquid is dried by long exposure to phosphorus pentoxide it may be evaporated without decomposition, but the molecules in the vapour are N_2O_4 . Nitrogen trioxide is the anhydride of nitrous acid, but only traces of this are formed by the action of water, since it is very unstable and the blue solution decomposes, partly into water and the anhydride (to which the colour is due) and partly with evolution of nitric oxide and formation of nitric acid: $3\text{HNO}_2 = \text{HNO}_3 + 2\text{NO} + \text{H}_2\text{O}$. Although the gas is largely composed of nitric oxide and nitrogen peroxide, it is rapidly absorbed by solutions of alkalis with formation of nitrites, *e.g.*, sodium nitrite, and by concentrated sulphuric acid with formation of nitroso-sulphuric acid ("chamber crystals"), $\text{SO}_2(\text{OH}) \cdot \text{O} \cdot \text{NO}$.

Sodium nitrite, NaNO_2 , is an important salt used in many organic preparations, *e.g.*, of dyestuffs, and is manufactured by heating molten sodium nitrate with metallic lead, by reducing sodium nitrate in presence of sodium hydroxide with sulphur

($3\text{NaNO}_2 + \text{S} + 2\text{NaOH} = \text{Na}_2\text{SO}_3 + 3\text{NaNO} + \text{H}_2\text{O}$), or, usually, by absorbing higher oxides of nitrogen obtained by the oxidation of air in the arc process or by the oxidation of ammonia, in sodium hydroxide or carbonate solutions. Nitrites are reducing agents, being converted to nitrates, but they also liberate iodine from potassium iodide, being reduced to nitric oxide.

The chloride of nitrous acid, *nitrosyl chloride*, NOCl , is a yellow gas formed by the direct union of nitric oxide and chlorine, by the action of phosphorus pentachloride on sodium nitrite, or by heating nitroso-sulphuric acid with sodium chloride.

Nitrogen peroxide (dioxide or tetroxide), NO_2 or N_2O_4 , is formed as a reddish-brown gas by the direct union of nitric oxide and oxygen. The later stages of this reaction are somewhat slow. It is more conveniently obtained by heating lead nitrate, $2\text{Pb}(\text{NO}_3)_2 = 2\text{PbO} + 4\text{NO}_2 + \text{O}_2$, and condensing the nitrogen peroxide to a liquid in a tube cooled in a freezing mixture, or (most conveniently and in a very pure state) by heating chamber crystals with potassium nitrate: $\text{SO}_2(\text{OH})\cdot\text{O}\cdot\text{NO} + \text{KNO}_3 = \text{KHSO}_4 + 2\text{NO}_2$. Nitrogen peroxide in a freezing mixture solidifies to nearly colourless crystals, melting at -9.04°C to a honey-yellow liquid. With rise of temperature this becomes reddish-brown and boils at 21.0°C , giving a reddish-brown vapour. The colour of the gas becomes deeper on heating; at 140°C it is nearly black. These colour changes are due to the existence of two forms of nitrogen peroxide: a colourless form, N_2O_4 , and a strongly coloured form, NO_2 . The conversion of N_2O_4 into NO_2 occurs in the liquid; in the vapour the change may be followed by the decrease in the vapour density due to dissociation: $\text{N}_2\text{O}_4 \rightleftharpoons 2\text{NO}_2$. The dissociation is complete at 140°C ; at higher temperatures NO_2 decomposes into NO and oxygen. On cooling the reverse changes occur.

Nitrogen peroxide supports the combustion of strongly burning phosphorus; it is decomposed at the temperature of the flame with formation of oxygen. A mixture of the gas with hydrogen is reduced to ammonia in contact with heated platinum. In contact with water, nitrogen peroxide is absorbed with the production of nitrous and nitric acids; the former then decomposes with formation of N_2O_3 and NO as explained above. The absorption of the gas with the formation of nitric acid, in presence of air or oxygen, which is an important industrial process, is therefore attended with difficulty. In presence of alkalis, nitrogen peroxide is absorbed with production of nitrite and nitrate: $2\text{KOH} + \text{N}_2\text{O}_4 = \text{KNO}_2 + \text{KNO}_3 + \text{H}_2\text{O}$. Liquid nitrogen peroxide forms a violently explosive mixture with petrol or other liquid hydrocarbons, and bombs filled with the mixture have been used in aerial bombardment. The gas, largely diluted with air, is used in bleaching flour.

Hyponitrous acid, $\text{H}_2\text{N}_2\text{O}_3$, (HON), is produced in the form of a salt by reducing nitrites with sodium amalgam (Divers, 1871), $2\text{NaNO}_2 + 4\text{Na} + 2\text{H}_2\text{O} = \text{Na}_2\text{N}_2\text{O}_3 + 4\text{NaOH}$. The free acid is obtained in the form of explosive crystals by the decomposition of the silver salt with hydrogen chloride in dry ether. The acid and its salts are powerful reducing agents. Salts of an acid $\text{H}_2\text{N}_2\text{O}_4$ (*nitrohydroxylamic acid*), intermediate between hyponitrous acid and nitrous acid, are also known. There is an isomeride of hyponitrous acid, *nitramide*, NO_2NH_2 .

Nitrogen pentoxide (nitric anhydride), N_2O_5 , first prepared by Deville (1849), is best obtained by the removal of water, by means of phosphoric oxide, from cooled, concentrated nitric acid: $2\text{HNO}_3 = \text{N}_2\text{O}_5 + \text{H}_2\text{O}$. The product is distilled in a current of ozonized oxygen, dried over phosphoric oxide and condensed in a vessel cooled by solid carbon dioxide and ether. An alternative method is to pass ozonized oxygen through cooled, liquid nitrogen tetroxide: $\text{N}_2\text{O}_4 + \text{O}_3 = \text{N}_2\text{O}_5 + \text{O}_2$. Crystals of nitrogen pentoxide are stable below 0°C but are very hygroscopic. At ordinary temperatures, especially on exposure to light, slow decomposition occurs into nitrogen peroxide and oxygen, while on heating the crystals melt with decomposition at 29.5°C . Sudden heating causes explosion. Nitrogen pentoxide dissolves in water forming nitric acid. Phosphorus and potassium burn in the liquid pentoxide on warming, and charcoal burns if previously ignited.

Nitroso-nitrogen trioxide (N_2O_4)₂ is a greenish solid obtained by passing nitric oxide through liquid oxygen, or by the action of

air on solid nitric oxide at the temperature of liquid air. It decomposes into nitrogen trioxide and nitric oxide above the temperature of liquid air (R. L. Hasche, 1925).

Nitrogen Halides.—*Nitrogen trichloride*, NCl_3 . Nitrogen does not combine directly with halogens, but compounds may be obtained indirectly. Nitrogen trichloride was obtained by Dulong (1811) by the action of chlorine on ammonium chloride solution. It can also be produced by the electrolysis of concentrated ammonium chloride solution or by treating ammonia with excess of chlorine. Gattermann showed that the latter reaction takes place in three stages: $\text{NH}_3 + \text{Cl}_2 = \text{NH}_2\text{Cl} + \text{HCl}$; $\text{NH}_2\text{Cl} + \text{Cl}_2 = \text{NHCl}_2 + \text{HCl}$; $\text{NHCl}_2 + \text{Cl}_2 = \text{NCl}_3 + \text{HCl}$. The intermediate compound NH_2Cl , monochloramine, has been isolated and forms colourless crystals melting at -66°C . It is unstable and explosive.

Nitrogen trichloride is a very dangerously explosive, volatile, yellow oil, boiling at 71°C . The vapour has a pungent odour and attacks the eyes and mucous membranes. The liquid explodes on contact with many substances or on exposure to bright light, but its solution in benzene may be safely handled in the dark. It is destroyed by ammonia.

Nitrogen iodide. Courtois (1812) obtained a black explosive powder by adding iodine to ammonia solution. This so-called "nitrogen iodine" was proved by Chattaway and Orton (1900) to be really the compound $\text{NI}_3\cdot\text{NH}_3$ and NI_3 is not known. When dry the substance explodes violently even when touched with a feather; in some cases the moist substance also explodes. It is an active oxidizing agent, and in all probability first forms hypoiodous acid, HOI , in presence of water. It is decomposed on exposure to light.

NITROGEN, FIXATION OF. Compared with the enormous quantity of nitrogen contained in the atmosphere, estimated at about 5.8 metric tons over each square yard of the earth's surface, the amount circulating in animals and plants is small, perhaps 1 in 500,000. Continual interchange takes place between atmospheric and combined nitrogen; some is returned to the soil as nitric acid in rain, some is fixed by the bacilli in the nodules formed on the roots of leguminous plants. Much of this nitrogen finds its way into the bodies of animals and plants; on the decay of such bodies ammonia is produced, and some of this is acted on by denitrifying bacteria which return the nitrogen to the air in an elementary condition. Until recent years the only artificial nitrogenous fertilizers used on an extensive scale were sodium nitrate from Chile and ammonium sulphate recovered from the ammoniacal liquors of gas-works and coke-ovens.

In ordinary circumstances, nitrogen is somewhat inert, but Henry Cavendish (1785) discovered that it unites with oxygen when electric sparks are passed through a mixture of the gases, and W. F. Donkin later obtained ammonia by the action of a silent electric discharge on a mixture of nitrogen and hydrogen. Any idea of using these reactions technically was abandoned for many years and more attention was paid to the possibility of synthesizing cyanides. As early as 1828 Desfosses found that a cyanide was produced when nitrogen was passed over a heated mixture of carbon and an alkali or alkaline carbonate. $\text{N}_2 + 4\text{C} + \text{K}_2\text{CO}_3 = 2\text{KCN} + 3\text{CO}$. If baryta be used in place of an alkali, barium cyanide is formed, and since this compound gives ammonia on heating strongly in steam, leaving a residue from which the baryta may be recovered, the reactions afford a possible technical process for the fixation of nitrogen (Margueritte and Sourdeval, 1860).

The establishment of the calcium carbide industry has made it

possible to combine nitrogen with carbon commercially, the calcium cyanamide produced giving calcium carbonate and ammonia as ultimate products of hydrolysis (A. R. Frank and N. Caro, 1895-8), $\text{CaC}_2 + \text{N}_2 = \text{C} + \text{CaCN}_2$ and $\text{CaCN}_2 + 3\text{H}_2\text{O} = \text{CaCO}_3 + 2\text{NH}_3$. This method underwent rapid development after the discovery that calcium cyanamide might be used directly as a nitrogenous fertilizer (1901). Certain metals form compounds with nitrogen which yield hydroxides and ammonia on treatment with water, e.g., (a) $\text{Li}_3\text{N} + 3\text{H}_2\text{O} = 3\text{LiOH} + \text{NH}_3$; (b) $\text{Mg}_3\text{N}_2 + 6\text{H}_2\text{O} = 3\text{Mg(OH)}_2 + 2\text{NH}_3$; (c) $\text{AlN} + 3\text{H}_2\text{O} = \text{Al(OH)}_3 + \text{NH}_3$. The price of the metals precludes their employment, but the discovery of O. Serpek, that aluminium nitride is formed when aluminium oxide (or bauxite) and carbon are heated in an atmosphere of nitrogen was actually used on a technical scale.

The development of nitrogen fixation during the present century has been made possible by a better understanding of the thermodynamics of chemical change and increased engineering resources. The manufacture of cyanamide was established rapidly as the necessary carbide was available and its production thoroughly understood. The actual reaction between carbide and nitrogen is exothermic (heat is evolved), and when initiated proceeds to completion. Nitrates and nitrites were manufactured on a large scale after 1903 by combining nitrogen and oxygen to nitric oxide at the temperature of the electric arc, and subsequently oxidizing the nitric oxide to nitric acid in the presence of water. Although the nitric oxide formation is endothermic (heat is absorbed), the large supply of energy was obtained at a cheap rate where water-power was available, notably in Norway. The exothermic synthesis of ammonia was the last fixation process to be developed technically; this was due to the slowness of the reaction $\text{N}_2 + 3\text{H}_2 \rightleftharpoons 2\text{NH}_3$.

Production.—Until the outbreak of the World War, the production of nitrates from ammonia had no apparent technical advantage. W. Ostwald had succeeded in greatly improving the yield of nitric oxide by the combustion of ammonia, $4\text{NH}_3 + 5\text{O}_2 = 4\text{NO} + 6\text{H}_2\text{O}$, and, with the shortage of nitrates, the process found adoption. The production of nitric acid from ammonia has now attained great importance, for whilst both ammonium salts and nitrates are used as fertilizers, the latter act more readily and hence enjoy considerable demand. It seems now to be more economical to use a given amount of electrical energy in the synthesis of ammonia and to burn this to nitric oxide rather than to use it in the direct formation of the latter compound. Thus in 1913 the greater portion of the combined nitrogen used in agriculture and the arts was derived either from Chilean nitrate or from ammonia compounds recovered from coke-ovens or gas-works, whilst at the present time synthetic nitrogen compounds predominate. The following figures for production of combined nitrogen are given on the authority of J. H. Lucas, *L'Industrie Chimique* (Jan. 1928, p. 11).

	1913-14		1925-26		1926-27	
	Tons	%	Tons	%	Tons	%
Chilean nitrate	425,000	56.66	400,000	30.0	210,000	16.8
Recovered ammonia	265,000	35.34	345,000	25.9	345,000	27.6
Synthetic compounds	60,000	8.00	580,000	44.1	605,000	55.6
	750,000		1,334,000		1,250,000	

The set-back in Chilean nitrate seems to have been temporary, for there was a recovery in consumption in 1928. A further increase took place in the fixation of nitrogen. Statistics given by F. A. Ernst and M. S. Sherman of the U.S.A. Fixed Nitrogen Laboratory (*Industrial and Engineering Chemistry*, Feb. 1927) assign the nitrogen fixed by synthetic processes in 1925 as follows:

	Tons	%
By arc process	41,000	6.7
As cyanamide	188,000	30.3
As ammonia	390,000	63.0
	619,000	100.0

The figures for cyanamide are possibly too low.

According to Ernst and Sherman, fixation of nitrogen has attained the largest proportions in Germany, where the annual capacity of plants is stated to be:—(a) arc process, 4,500; (b) cyanamide, 94,000; (c) synthetic ammonia, 402,500 in tons of nitrogen. France, Italy, Japan, Norway and Canada are also noted for large plant capacity. Respecting the United States, M. S. Sherman (*Ind. and Eng. Chem.*, Jan. 1928) states that 12,800 tons were fixed in 1926 whilst the probable figure for 1927 is 23,000 tons. Production is rapidly increasing in Great Britain and the Billingham Works which were making about 65 tons of ammonia *per diem* in 1926 are expected to attain an annual output of 750,000 tons of ammonium sulphate (over 150,000 tons of nitrogen) in 1930. The sulphate radicle is now frequently obtained from natural calcium sulphate (anhydrite or gypsum) by utilizing the reaction, $\text{CaSO}_4 + 2\text{NH}_3 + \text{CO}_2 + \text{H}_2\text{O} = \text{CaCO}_3 + (\text{NH}_4)_2\text{SO}_4$. Combined nitrogen is also being supplied for agricultural purposes as urea (from ammonia and carbon dioxide) and in many fertilizers containing potash and phosphates.

Synthesis of Ammonia.—The combination of nitrogen and hydrogen is accompanied by the evolution of heat, the equation for the formation of ammonia at ordinary temperature being

according to the measurements of Julius Thomsen. (See also papers by Haber and his co-workers between 1903 and 1915.) The heat evolved at higher temperatures is progressively less, and the amount of ammonia existing in true equilibrium with a mixture of one volume of nitrogen and three volumes of hydrogen diminishes, as temperature is raised. If ammonia, nitrogen and hydrogen co-exist in an enclosed space, each gas can be considered as occupying the whole volume but exercising a partial pressure proportional to the number of its molecules present. For any given temperature, certain concentrations of the different gases will be in equilibrium when

$$\frac{(p_{\text{NH}_3})^2}{(p_{\text{N}_2}) \times (p_{\text{H}_2})^3} = \text{a constant}$$

the p 's representing the respective partial pressures of the gases whose formulae are put down as suffixes. It is more convenient in practice to take the square root and write

$$\frac{p_{\text{NH}_3}}{p_{\text{N}_2}^{1/2} \times p_{\text{H}_2}^{3/2}} = K_p$$

If a mixture of these three gases be compressed, ammonia must be formed in order to preserve the above relationship, so that rise of temperature and of pressure act in contrary directions, the first diminishing the equilibrium amount of ammonia, the latter increasing it.

Since nitrogen and hydrogen react to form ammonia very slowly, no change is observed if these gases are mixed at ordinary temperature and pressure and left for years. In order to get appreciable change the reaction must be accelerated, and the two ways in which this is possible are by increase in temperature and use of a catalyst. In Haber's earlier experiments (with G. van Oordt), ammonia was passed over a heated catalyst and the ammonia which had escaped decomposition absorbed and estimated. The residual nitrogen and hydrogen were passed over another portion of catalyst at the same temperature and the ammonia formed estimated: the two sets of experiments showed fair agreement but were found later to be too high as regards ammonia formation. (Haber and R. le Rossignol, also F. Jost, 1908.) From a knowledge of heats of formation and specific heats of reacting gases, the equilibrium constant can be calculated theoretically.

Catalysts.—Ultimately agreement between theoretical and practical results was obtained and it became obvious that, for practical working, a catalyst would have to be found which was sufficiently rapid in its action about 500° C and not too susceptible to "poisoning" by impurities in the gases employed. Theoretically, the following approximate percentages of ammonia may be attained.

Temperature	500°	550°	600°
At 100 atmospheres.	11.0	7.0	4.5
At 200 atmospheres.	18.0	12.0	8.0

Haber used various catalysts in the course of his work. In the early stages, osmium and ruthenium were found to give good results but price and rarity preclude their use. The catalysts usually contain iron with a basic oxide (introduced by fusion) as a promoter. A large number of patents have been taken in the first quarter of the 20th century, and the firms concerned do not divulge the nature of the catalysts they employ. The Badische Co. have been supposed to use an iron catalyst with (possibly) molybdenum as promoter. In the war plant of the U.S. Government, pumice was impregnated with nickel or iron sulphate, heated to 550°, reduced by hydrogen and treated with sodium and ammonia gas at 450°; sodamide was formed in the spongy metal, and such a mass is said to act at 500° and 70 atmospheres. Synthetic Ammonia and Nitrates Ltd. claim that calcium ferrite, prepared in the electric furnace, gives an active catalyst on subsequent reduction (Brit. Pat. 237,394). Norsk-Hydro mix compounds of metals of the iron group with cyanides in liquid anhydrous ammonia, remove the excess of ammonia and heat in a non-oxidizing atmosphere (U.S. Pat. 1,570,333). F. Uhde (Brit. Pat. 247,225) carefully avoids water. In an example, anhydrous ferric chloride and potassium ferrocyanide react in glycol solution, the precipitate is dried *in vacuo*, filled into the furnace and treated with nitrogen and hydrogen, first without and then with increased pressure at 350–450°. The hydrogen used in the synthesis is chiefly produced from coke and steam but electrolytic, coke-oven and by-product hydrogen are also used. Nitrogen is obtained by rectification of liquid air or from producer-gas.

Haber-Bosch Process.—This process was developed by the Badische Co. (now part of I. G. Farbenindustrie A.-G.) and is carried out at about 500° and 200 atmospheres. The necessary mixture of nitrogen and hydrogen is obtained from water-gas and producer-gas. Air is blown through a coke fire, shut off and steam blown through when the reaction, $C + H_2O = CO + H_2$, takes place. The mixture actually contains about 50% hydrogen, 42–45% carbon monoxide and a small balance, chiefly carbon dioxide and nitrogen. The producer-gas from air and coke contains hydrogen, 5–15%; nitrogen, 65–50%; carbon monoxide, 20–30% and residue of carbon dioxide, methane, etc. Suitable proportions give a gas mixture with 22–23% nitrogen and remainder mostly hydrogen and carbon monoxide. By passage over a catalyst with excess of steam, the reaction $CO + H_2O = CO_2 + H_2$ is driven as far as possible to the right to give a gas mixture with about 17% N_2 , 52% H_2 , 27 to 29% CO_2 , 2 to 4% CO and small amounts of argon, methane, etc. The carbon dioxide can be reduced to under 1% by water scrubbing under pressure, the remainder is washed out with cold alkali solution. Removal of carbon monoxide and residual sulphur compounds is essential as they are catalyst poisons; for the former, a solution of cuprous ammonium carbonate (or formate) may be employed. Treatment with ammonia is also used (e.g., Synthetic Ammonia and Nitrates Ltd., Slade and Parkes, Brit. Pat. 240,350; Casale, Brit. Pat. 231,417). F. Uhde finally cleanses and dries the gas-mixture by passage through a melt of sodium amide containing a metal of the alkali or alkaline earth class. 20% sodium and 80% sodamide can be used at 200–250° C, the contact of the gas and melt lasting 20 to 60 seconds. (Brit. Pat. 247,226.)

According to Waeser, the gas mixture passes a three-stage compressor and the reaction is carried out in tubular vessels of special steel. Once the reaction is started, further heating is unnecessary and heat may have to be taken away. The gases leave the catalyst with about 10% of ammonia which is removed after cooling by washing with water.

Other Processes.—G. Claude increases the pressure to 600 or 1,000 atmos.; this so displaces the equilibrium towards ammonia formation that higher temperatures (500–600°) can be employed, at which the catalysts are more active and less sensitive to poisoning. Up to 20% of ammonia may be attained and if the

issuing gases are cooled under this pressure, the ammonia is mostly liquefied and may be removed in an anhydrous condition. Usually three contact units are used in series. After passage through each unit, the gas is cooled and the liquefied ammonia removed, the remaining nitrogen and hydrogen being passed on to the next unit. A suitable steel for the high pressure apparatus is said to contain Si, 0.018%; S, 0.09%; C, 0.098%; and Mn, 0.93%. Chrome-vanadium steel is also employed for reaction chambers. The process is worked with hydrogen from water-gas or coke-ovens whilst electrolytic hydrogen is also employed, as at Bussi (Italy). Claude gives the following equilibria for ammonia at 536°.

Atmospheres pressure	200	400	600	800	1,000
Ammonia per cent	12.5	21.0	28.5	36.0	41.0

Discrepant statements have been made as to the pressure employed by L. Casale in the process named after him; it is probably about 800 atmos., the gases circulating in a closed circuit. A characteristic of the process is that a certain percentage of ammonia is returned with the nitrogen-hydrogen mixture in order to avoid overheating the catalytic mass. Only a portion of the ammonia is removed from the gas after leaving the synthetic tube and uncombined gases are made to pass repeatedly over the catalyst. Many important details have been worked out with respect to heat-interchangers and the maximum temperature of the pressure containers. This process has been largely adopted and is worked with nitrogen from various sources.

Cyanamide.—The ultimate raw materials are limestone, some form of carbon (charcoal, anthracite or coke) and atmospheric nitrogen. The limestone is burnt to lime, the latter heated in an electric furnace with carbon and the resultant calcium carbide brought to reaction with nitrogen (99.8% purity). Henri Moissan found that pure calcium carbide did not react with nitrogen on heating but Frank and Caro obtained cyanamide from commercial, impure carbide. The reaction is one which may be catalysed and calcium fluoride has been used for this purpose. Calcium chloride is also effective but undesirable as it attracts moisture.

The ovens in which the reaction between carbide and nitrogen is effected are either discontinuous or continuous in action. In the first case they are usually cylindrical in shape and charged with finely ground carbide around a carbon pencil. The covers are placed in position, nitrogen admitted under slight pressure and the carbon pencil heated electrically. The carbide surrounding the pencil soon attains the necessary temperature; when the reaction has well started further electrical heating is unnecessary and the reaction spreads from the core outwards until the entire charge is converted. This may take 24 to 40 hours.

The crude product contains about 60% calcium cyanamide (21% nitrogen), 20% lime, 12% free carbon and a small amount of aluminium and iron oxides, silica, etc. Cyanamide is manufactured on a large scale in Germany and France and in substantial quantities in other countries. It is largely used as a fertilizer; a certain amount is converted into ammonia and then into ammonium sulphate.

Oxidation of Nitrogen.—(a) At a high temperature, nitrogen and oxygen partially combine to form nitric oxide, the reaction being reversible.

The reaction is endothermic, i.e., heat is absorbed, so that the higher the temperature, the greater the quantity of nitric oxide in equilibrium with nitrogen and oxygen. At ordinary temperatures, the amount of nitric oxide is negligible for true equilibrium, but the rate of decomposition of nitric oxide is so slow that, if the mixture of gases be rapidly cooled, most of the nitric oxide formed at a high temperature may be preserved.

(b) Nitric oxide unites directly with oxygen at ordinary temperatures to form nitrogen peroxide, $2NO + O_2 = 2NO_2$.

(c) Nitrogen peroxide reacts with water to form nitric acid and nitric oxide, $3NO_2 + H_2O = 2HNO_3 + NO$. If excess of oxygen be present, the nitric oxide is again oxidized to nitrogen peroxide,

so that the net result will be given by the equation, $4\text{NO}_2 + \text{O}_2 + 2\text{H}_2\text{O} = 4\text{HNO}_3$.

On the theoretical side, the equilibrium between nitrogen oxygen and nitric oxide is given by

$$\frac{[\text{NO}]^2}{[\text{N}_2] \times [\text{O}_2]} = \frac{x^2}{\left(79.2 - \frac{x}{2}\right) \left(20.8 - \frac{x}{2}\right)} = \text{constant } k.$$

The square brackets indicate the concentrations of the respective gases and the expression involving x represents the values if atmospheric air be taken as initial material. It is known that k is related to the heat of formation (q) thus,

$$\frac{d \log k}{dT} = - \frac{q}{RT^2}$$

so that if x be determined at an absolute temperature T , k may be calculated for that temperature and a value of q obtained. W. Nernst used the heat of formation of nitric oxide determined by J. Thomsen, viz.—43,200 cal., and compared theoretical and practical values of x . Thus at $1,811^\circ$, x was observed to be 0.37 and calculated as 0.35, whilst at $2,675^\circ$ the respective values were 2.23 and 2.35. Nernst and his fellow-workers used external electric heating, but in 1903 W. Muthmann and H. Hofer had obtained 3.6 to 6.7% of nitric oxide when the air was exposed directly to the arc. 7% would correspond to a temperature of $3,750^\circ$, but experiments by Haber and A. Koenig point to a specific influence of the arc; there seems to be an "electric equilibrium" in addition to the thermal equilibrium.

Patents for the synthesis of nitric acid were taken by Mme. Lefebvre (1859) and McDougall (1899), but manufacturing on a commercial scale was first started by C. S. Bradley and R. Lovejoy (Brit. Pat. 8,230/1901; U.S.P.P. 709,867; 709,869). The air was driven through a vertical iron cylinder containing a rotating steel shaft, both tube and shaft were provided with electrodes and between them, 6,900 arcs were struck and broken per second. The process was not operated after 1904, more efficient processes having made an appearance.

Another method of exposing air to the arc is due to O. Schönherr (1905). An arc (which may be from direct current) of 16 to 23 ft. in length is set up in a vertical tube: the lower electrode is an iron rod which is gradually worn away, the wastage is small and the expense of renewal trifling. A water-jacket surrounding the upper part of the tube serves as the other electrode; since the arc varies in length, it does not always strike the same area and wear and tear are small. Air passes upwards along this tube, returns downwards through a concentric outer tube and serves partially to heat the incoming air.

After leaving the electric furnace, the gases are cooled (much heat may be usefully recovered) and pass on to an oxidation tower. By treatment in a succession of towers with water in counter-current, a weak nitric acid is recovered which may be concentrated or, more usually, neutralized with lime or ammonia for the production of calcium or ammonium nitrate. The former is utilized as a fertilizer, the latter finds a use in explosives. The washing with water does not remove all the oxides of nitrogen; more complete exhaustion is effected by spraying the remaining gas with solution of soda ash, sodium nitrate (fertilizer) or sodium nitrite (dyestuff industry) being recovered.

The Birkeland and Eyde process was established in 1903 and utilized largely by the Norsk-Hydro Co. at Notodden and later at Rjukan. The Schönherr process was largely developed by the Badische Co. and introduced at the above mentioned Norwegian works. The German capital was afterwards withdrawn from the Norsk-Hydro owing to the development of the Haber process. The Pauling process was used in France, Austria and Italy, whilst another arc process, the invention of Mosicki, was established in Switzerland.

Several methods for the recovery of oxides of nitrogen formed at high temperatures in combustion processes have been suggested; of these, that due to F. Häusser with respect to internal combustion engines has received most publicity.

Oxides of Nitrogen from Ammonia.—When ammonia is burnt under ordinary conditions, nitrogen and water vapour are the chief products. That oxides of nitrogen may be formed was observed in the eighteenth century and in 1839 Kuhlmann found the reaction was catalysed by platinum. Shortly before the war, W. Ostwald fixed the conditions by which fair yields can be obtained.

The usual catalyst is platinum gauze (80 to 150 mesh per in., wire diameter 0.001 to 0.003 in.), four layers being frequently employed. A pre-heated mixture of ammonia and air is blown through the catalyst; the time of contact with the platinum is 0.0001 sec. and the temperature $1,000^\circ \text{C}$; the speed is important. With good conditions the reaction, $4\text{NH}_3 + 5\text{O}_2 = 4\text{NO} + 6\text{H}_2\text{O}$, can be realized to the extent of about 95%. If all the ammonia is not oxidized it subsequently reacts with the oxides of nitrogen. It is reported that a granular iron oxide mixed with other oxide promoters has been used successfully in place of platinum. The oxidation of the nitric oxide and recovery as nitrates and nitrites follows, as previously described.

BIBLIOGRAPHY.—*Physical and Chemical Data of Nitrogen Fixation, and Report of the Nitrogen Products Committee* (Stationery Office, London, 1918 and 1919 resp.); J. R. Partington and L. H. Parker, *The Nitrogen Industry* (1922), contains many illustrations; *Report on the Fixation and Utilization of Nitrogen* (Washington, 1922) contains flow-sheet diagrams and bibliography to 1922; B. Waeser, *Die Luftstickstoffindustrie* (Leipzig, 1922), trans. by E. Fyleman and J. and A. Churchill, as *The Atmospheric Nitrogen Industry* (1926) with appendices to bring the information up-to-date; J. R. Partington, "Nitrogen Fixation" in Thorpe's *Dictionary of Applied Chemistry*; articles in Ullmann's *Encyclopaedie der technischen Chemie* (1914–22); *Badische Anilin- und Soda-Fabrik* (published by the firm, 1925). UNITED STATES

While the industrial fixation of atmospheric nitrogen had its birth in the United States when the Atmospheric Products Company was organized at Niagara Falls, N.Y., to exploit the Bradley and Lovejoy patents, little nitrogen was fixed in the United States until after the World War. A Pauling furnace was operated at Nitrolee, S.C., from 1913 to 1916. Another plant was operated by the arc process at Le Grande, Wash., for ten years. The excessive cost of electric energy, however, made it impossible for these plants to compete with the synthetic ammonia plants. The American Cyanamid Company began the operation of the process, for which it is named, in 1907, and has increased its capacity from time to time. The U.S. Nitrate Plant No. 2 at Muscle Shoals, Ala., was also erected to operate the cyanamide process, but has never produced commercially. ("Muscle" is the common spelling of "mussel" in the Colonial period.)

The first attempt in the United States to synthesize ammonia directly was at U.S. Nitrate Plant No. 1, Sheffield, Ala., but this was an experimental plant, the continuous operation of which was never realized. Following the war the Atmospheric Nitrogen Corporation began operations at Syracuse, N.Y., reaching in 1927 an annual capacity of 11,550 tons. A number of small plants followed, using for the most part by-product hydrogen. These were soon followed by a plant at Seattle, Wash., using electrolytic hydrogen, and Lazote, Inc., at Charleston, W. Va., employing water-gas hydrogen, with a production capacity of 6,350 tons in 1927. In 1928, at Hopewell, Va., the first unit of a plant of some 30,000 tons capacity began the manufacture of synthetic sodium nitrate, having the distinction of being the first plant to produce directly a synthetic material identical with Chilean nitrate. Synthetic ammonia processes operating in the United States are for the most part modifications of the Haber, Casale and Claude processes. However, there has been developed a modification so extensive as to entitle it to be known as an "American Process." This has proved such an efficient method for fixing atmospheric nitrogen as to be installed in the newer plants erected both at home and abroad. (H. E. H.)

NITROGEN HARDENING, a process of hardening alloy steel at low temperature in ammonia gas. This process was first described in 1926 by Dr. A. Fry, a German metallurgist at Krupp's and has since been widely used for parts requiring high strength, resistance to wear and toughness, a combination of properties not

easy to obtain in similar degree by any other process. Medium carbon steels containing up to 1% aluminium are required for the process. It has been found that a little chromium is of advantage, while about half of 1% molybdenum is added to prevent brittleness. This steel is first normalized to remove strain and give easy machineability; it is then machined and ground to finished dimensions, next placed loosely in a closed pot, heated 10 to 15 hours in a slow stream of ammonia gas at 500° C and cooled without removing from the pot. The temperature is so low that no warping will occur; the surface is unscaled but extremely hard. Hardness at a depth of 0.01 in. is as high as is obtained from the ordinary case hardening pots. The aluminium in the steel is a good corrosion repellent, and this together with the natural chemical inactivity of a hardened surface lends interesting possibilities for using ammonia treated members in rust-resisting structures. (See CASE HARDENING; CEMENTATION; IRON AND STEEL.) (E. E. T.)

NITROGLYCERIN, an explosive first obtained in 1846 by Ascanio Sobrero by acting with a mixture of strong nitric and sulphuric acids on glycerin at the ordinary temperature. It is in fact the ester (see ESTERS) of glycerol and other molecules of nitric acid, having the constitutional name of glyceryl trinitrate and the formula $C_3H_5(NO_3)_3$ or $CH_2NO_3 \cdot CHNO_3 \cdot CH_2NO_3$.

It is a very pale yellow oil of sp. gr. 1.614 at 4° C and 1.60 at 15° C. One gram requires for solution between 800 and 1,000 c.c. of water, 4 c.c. of absolute alcohol or 18 c.c. of wood spirit. It is scarcely soluble in glycerin, but mixes in all proportions with ether, acetone, ethyl acetate and benzene. (See EXPLOSIVES.)

Therapeutics.—Nitroglycerin has a sweet burning taste and is decidedly poisonous. Its vapour produces violent headache, and the same effect is often caused by handling compositions containing it. Although a nitrate, its pharmacological actions resemble those of nitrites such as amyl nitrite, taken internally. The explanation is that in an alkaline medium at body heat nitroglycerin yields a nitrite, probably as a preliminary stage of resolution. This gradual conversion in the tissues is a valuable property of nitroglycerin, as its effects take longer to manifest themselves than is the case with amyl and other nitrites. Nitroglycerin is valuable as a preventive in cases of cardiac pain, such as angina pectoris.

NITROSOBENZENE, C_6H_5NO , first obtained by the action of nitrosyl bromide or chloride on mercury diphenyl, is prepared by the oxidation of β -phenylhydroxylamine with chromic acid. It results from the oxidation of aniline by monopersulphuric acid (H. Caro). It exists in two crystalline forms. It melts at 68° to an emerald-green liquid which solidifies to colourless crystals melting at 57–59°. It is very volatile and its solutions are green. Nitric acid oxidises it to nitrobenzene. It condenses with aromatic amines to form azo-compounds, with arylhydroxylamines to form azoxy-compounds, and with hydroxylamine it gives isodiazobenzene hydroxide.

NITTI, FRANCESCO SAVERIO (1868–), Italian statesman, was born at Meli (Potenza). He had already become known as a barrister and as professor of financial science at the University of Naples when he entered parliament in 1904. He made his reputation as an authority on economic and financial questions, and was minister of agriculture, industry and trade in the Giolitti cabinet of 1911–14. When the United States entered the World War in 1917, he was entrusted with an economic mission to that country, and certain of his utterances and acts in this connection were severely criticised. He became minister of the treasury in the Orlando cabinet from Oct. 1917 to Jan. 1919. On the fall of the Orlando ministry, which he helped to bring about, he succeeded as premier.

Nitti's adoption of the system of proportional representation resulted in an important increase in the Socialist and Popolari deputies at the elections of Nov. 1919, but he failed to conciliate either group. The epidemic of revolutionary strikes and disorders, seriously weakened his position, and he felt forced to resign on March 12, 1920. But no other statesman being willing to assume the succession, he reconstructed his cabinet; defeated in the Chamber after the San Remo meeting of the Supreme Council presided over by him, to prepare the peace with Turkey, he resigned

a second time but again reconstructed his cabinet. The arrest ordered by him of the Dalmatians and Fiumani in Rome provoked further irritation, and while he at first reduced the bread subsidy for financial reasons, he revoked the decree immediately afterwards from fear of the Socialist menaces, and resigned for the last time on June 9, 1920, leaving the door open for Giolitti's return.

On retiring from office he returned to journalism and business. In parliament he opposed Giolitti, but was still more hostile to the Fascists. He was re-elected in 1921, but did not stand in the 1924 elections held under Mussolini's auspices. His house was looted by Fascists, and he himself subsequently left Italy.

Nitti wrote several books on economic questions, including one entitled *Nord e Sud* (1900), dealing with what he regards as the unfair treatment of South Italy by the wealthier North, and *L'Italia all'alba del secolo XX.* (1901). Among his other works, the following have been translated into English: *L'Europa senza pace* (Eng. trans. 1922); *La Decadenza dell'Europa* (Eng. trans. 1923); *La Tragedia dell'Europa* (Eng. trans. *They Make a Desert*, 1924). In 1925 his son Vincenzo Nitti published a vindication of his father's policy, *L'opera di Nitti*.

NITZSCH, KARL IMMANUEL (1787–1868), Lutheran divine, was born near Leipzig on Sept. 21, 1787. He studied at Wittenberg, where he began to teach in 1809. From 1820 to 1822 he was superintendent in Kemberg, and in the latter year he was appointed professor of theology at Bonn where he remained until called to succeed Marheineke at Berlin in 1847. Subsequently he became university preacher, rector of the university, provost of St. Nicolai (in 1854) and member of the supreme council of the church, in which last capacity he was one of the ablest and most active promoters of the Evangelical Union. He died on Aug. 21, 1868. He represented the *Vermittlungstheologie* of the school of Schleiermacher, holding "that religion is not doctrine but life, direct consciousness, feeling."

His principal works are: *System der christlichen Lehre* (1829; 6th ed., 1851; Eng. trans., 1849), *Praktische Theologie* (1847–60; 2nd ed., 1863–68), *Akademische Vorträge über christliche Glaubenslehre* (1858) and several series of *Predigten*.

NIUÉ (SAVAGE ISLAND): see PACIFIC ISLANDS.

NIVELLE, ROBERT GEORGE (1856–1924), French soldier, was born on Oct. 15, 1856, at Tulle, Corrèze. He entered the Polytechnic in 1876, and left two years later to join the artillery. He served in China in 1900, and then for many years in Algeria. When the World War broke out he was in command of the 5th Artillery at Besançon.

Appointed a general of brigade on Oct. 24, 1914, he fought successfully on the Aisne, and in Jan. 1915 took a prominent part in the attack on Quesnevières. On Dec. 23, 1915, he was placed at the head of the III. Corps, and in March 1916 was sent to Verdun, where after some remarkable fighting he succeeded in checking the Crown Prince's first attack. On May 2 he succeeded General Pétaïn in the command of the II. Army, and definitely held the enemy before that glorious citadel. It was he who, in orders which have become famous, made the unforgettable declaration: "Ils ne passeront pas." On March 12, 1916, he succeeded General Joffre as commander-in-chief of the armies of the north and north-east. In conjunction with the British armies he prepared the great offensive of April 16 between Soissons and Auberive. After this semi-defeat he was replaced by General Pétaïn in the command of the French armies. On May 15, 1917, he was appointed commander of the armies "chargé de mission," and on Dec. 23, 1917, took over the French troops in North Africa.

On Oct. 14, 1918, General Nivelle was confirmed in his command despite the rules of superannuation, and on Jan. 30, 1920, was nominated a member of the Supreme War Council. On March 5, 1920, he gave up the command of the XIX. Corps, and in Nov. 1920 he was ordered to represent France in the United States at the tercentenary of the arrival of the "Mayflower." He was placed on the retired list on Oct. 11, 1921; he died on March 23, 1924. (M. Gu.)

NIVELLES (Flem. *Nyvel*), town, province of Brabant, Belgium, on the Thines 19 m. south of Brussels. Pop. (1925) 12,966

It manufactures parchment, cardboard and paper. The town is supposed to owe its origin to the foundation of a convent by Itta or Idaberge, wife of Pippin of Landen, and it is the cradle of the Carolingians. The Romanesque church of St. Gertrude, named after Itta's daughter, dates from the 11th century. On the top of the tower is the effigy of a man in iron who strikes the hours with a hammer. He is called by the townspeople Jean de Nivelles, a celebrated baron of the 15th century whose title eventually became merged in that of the count de Hornes (Horn). Close to Nivelles is Seneffe, where Condé defeated William of Orange in 1674. At Nivelles the French under Marceau defeated the Austrians in 1794.

NIVERNAIS, formerly a province and duchy of France, bounded on the north by Gâtinais-Orléanais and Auxerrois, on the south by Bourbonnais, on the east by Burgundy, on the west by Berri. It is embodied almost entirely in the present department of Nièvre. The capital of Nivernais was Nevers. At the Roman conquest Nivernais was a part of the territory of the Aedui. Nivernais was included in the jurisdiction of the *parlement* of Paris, and was a *gouvernement militaire*. From the time of the Merovingians it comprised the diocese of Nevers.

See Guy Coquille, *Histoire du Nivernais* (1612); F. Gillois, *Chronique du Nivernais* (1867).

NIXIE or **NIXY**, a female water-sprite. The word is adapted from Ger. *Nixe*, the male water-sprite being *Nix*. The general term covering both the male and female is "nicker," a kelpie. This also appears in Dutch *nikker*. The Old Teutonic *nikus* may be connected with the root which appears in Gr. *νίξειν* or *νίπτειν* "to wash."

NIXON, JOHN (1815–1899). English mining engineer and colliery proprietor, was born at Barlow, Durham, on May 10, 1815, the son of a farmer. He was a mine-surveyor on the South Wales coalfield, and he then became engineer to a French coal and iron company. Returning to England, he noticed while travelling on a Thames steamer that the Welsh coal in use gave off no smoke, and was preferred to north country coal both on this ground and because of its greater power-producing efficiency. His experience in France suggested that a profitable market for this coal might be established among the French iron-founders and manufacturers generally who had hitherto imported English north country coal. Eventually he freighted a small craft, and sent it across to Nantes, where he persuaded the local manufacturers to try it on the understanding that he bore the expense of the experiments. These tests, under his direction, proved successful, and his visit to Nantes laid the foundations of the Welsh steam-coal trade, English manufacturers and shipowners imitating the example of their French rivals. Nixon eventually acquired a colliery, known as Nixon's Navigation collieries in the Aberdare valley, and later acquired or developed other South Wales steam collieries. He invented many mechanical improvements in colliery working. He died in London on June 3, 1899.

See J. E. Vincent, *John Nixon, Pioneer of the Steam Coal Trade in South Wales* (1900).

NIZĀMĪ (1140–1—1202–3). Nizām-uddīn Abū Mohammed Ilyās bin Yūsuf, Persian poet, was born A.H. 535 (A.D. 1140–1). His native place, or at any rate the abode of his father, was in the hills of Kum, but as he spent almost all his days in Ganja in Arrān (the present Elizavetpol) he is generally known as Nizāmī of Ganja or Ganjawi. Nizāmī abandoned himself at an early age to a stern ascetic life, as full of intolerance to others as dry and unprofitable to himself. The first poetical work in which Nizāmī embodied his thoughts on God and man, and all the experiences he had gained, was *Makhzanul Asrār* (c. 1165–6) or "Storehouse of Mysteries," and bears the unmistakable stamp of Sūfī speculations. His claim to the title of the earliest Persian romanticist he fully established only a year or two after the *Makhzan* by the publication of his first epic masterpiece *Khosrau and Shirin* (c. 1175–6), reciting the ancient tale of the loves of Chosroes and Shirin. It was composed, according to the oldest copies, in A.H. 576 (A.D. 1180), and inscribed to the reigning atābeg of Azerbaijan, Abū Ja'far Mohammed Pahlavān, and his brother Kizil Arslān, who, soon after his accession to the throne in A.H. 582, showed his gratitude to the poet by summoning him to his court,

loading him with honours, and bestowing upon him the revenue of two villages, Hamd and Nijān. In 1188 Nizāmī completed his *Diwān*, or collection of kasidas and ghazals (mostly of an ethical and parenetic character), which are said to have numbered 20,000 distichs, although the few copies which have come to us contain only a very small number of verses. About the same time he commenced, at the desire of the ruler of the neighbouring Shīrvān, his second romantic poem, the famous Bedouin love-story of *Laila and Majnūn* (c. 1188–9). His *Iskandarnāma* (1191) or "Book of Alexander," also called *Sharafnāma* or *Iqbāl-nāma-i-Iskandari* ("The Fortunes of Alexander"), is split into two divisions, the first based on the historical career of Alexander, which is embroidered by many magical tales, among others the voyage of Alexander to the fountain of life in the land of darkness; the second describing him as prophet and philosopher. Nizāmī's last romance *Haft Paikar* (1198–9), or the "Seven Beauties," comprises seven tales in verses related by the seven favourite wives of the Sassanian king Bahrām-gūr. Among these is the tale of the Russian princess used by Gozzi and Schiller, "Turandot." The five mathnawīs, from the *Makhzan* to the *Haft Paikar*, form Nizāmī's so-called "Quintuple" (*Khamsa*) or "Five Treasures" (*Panj Ganj*), and have been taken as pattern by all the later epic poets in the Persian, Turkish, Chaghatāi and Hindustāni languages. Nizāmī died at Ganja in his sixty-fourth year, A.H. 599 (A.D. 1202–3).

BIBLIOGRAPHY.—The fullest account of Nizāmī is given in Dr. W. Bacher's *Nizāmī's Leben und Werke* (Leipzig, 1871; English translation by S. Robinson, London, 1873; reprinted in the same author's *Persian Poetry for English Readers*, 1883, pp. 103–244). All the errors of detail in Bacher's work have been corrected by Dr. Rieu in his *Catalogue of the Persian MSS. in the British Museum* (1881), ii. 563 sqq.

Principal Editions.—The whole *Khamsa* (lithographed, Bombay, 1834 and 1838, Teheran, 1845); *Makhzan-ul Asrār* (edit. by N. Bland, London, 1844, lithographed, Calcutta, 1869, English translation in ms. by Hatton Hindley, in the British Museum Add. 6961); *Khosrau and Shirin* (lithographed, Lahore, 1871, German translation by Hammer in *Shirin, ein persisches romantisches Gedicht*, Leipzig, 1809); *Laila and Majnūn* (lithographed, Lucknow, 1879; English translation by J. Atkinson, London, 1836); *Haft Paikar* (lithographed, Bombay, 1849, Lucknow, 1873; the fourth tale in German by F. von Erdmann, *Behramgur und die russische Fürstentochter*, Kasan, 1844); *Iskandarnāma*, first part, with commentary (Calcutta, 1812 and 1825, text alone, Calcutta, 1853, lithographed with marginal notes, Lucknow, 1865, Bombay, 1861 and 1875, English translation by H. Wilberforce Clarke, London, 1881; compare also Erdmann, *De expeditione Ruserum Berdaam versus*, Kasan, 1826, and Charmoy, *Expédition d'Alexandre contre les Russes*, St. Petersburg, 1829); *Iskandarnāma-i-Bakrī*, second part, edited by Dr. Sprenger (Calcutta, 1852 and 1860).

NIZHEGOROD (an abbreviation from Nijni-Novgorod), a province of the Russian S.F.S.R., bounded on the east by Vyatka, the Marii autonomous area and the Chuvash Autonomous Socialist Soviet Republic, on the south of Uliyanovsk, Penza and Ryazan, on the west by Vladimir, Ivanovo-Vosnesensk and Kostroma, and on the north by the North Dwina province. Area 78,208 square kilometres. Pop. (1926) 2,736,221. It is smaller than the pre-1917 province of Nijni-Novgorod. The northern portion consists of a pine forest area lying along each side of the Vetluga river from the point where it curves sharply to the south, though the lower course of the Vetluga, and its junction with the Volga, lie in the Marii area. The forest approaches the left bank closely, but along the right bank there are a series of settlements in the forest free strip. South of the Volga is a fertile black earth area, between the Oka on the west, which forms the boundary of the province in the south-west, and then flows through the province of Vladimir, finally turning sharply to the east and flowing through the Nizhegorod province to its junction with the Volga, and the Sura on the east, which flows through the Chuvash Autonomous Socialist Soviet Republic in the south, but forms the boundary between that republic and the Nizhegorod province in the north of its course. This southern part has little forest and consists of high plains, with river valleys entrenching them, and the valley black earth is the most fertile soil in entire area of the province.

The southern part is not favourable to grass and meadow cultivation, so that dairying has not developed. Grain cultivation occupies 85% of the ploughed land, the chief crops being rye and

oats, with a little wheat, millet and buckwheat. Potatoes, flax and a little hemp are grown. Fruit and vegetables are cultivated along the Oka and Volga and find a ready market in Nizhny-Novgorod. Sheep, cattle, horses, pigs and goats are reared. The province is sparsely peopled, especially in the north; the population is mainly Great Russian, though there are Mordvinian and Tatar colonies in the south-east. Bog iron ores, sand, salt and phosphorite are found. The province is rich in peat, and the electric station opened in 1925-26 at Balakhna, on the Volga, north of Nizhny-Novgorod, works on peat fuel and has a power of 20,000 kilowatts. Factory industries include the making of machinery for railway and river transport, and for local peasant industries, flour-milling, distilling, saw-milling and the manufacture of cardboard and paper, brewing and the making of leather goods. The poor guarantee for agriculture has led to a great development of koustar (peasant) industry, especially the making of wooden articles (41%) and textiles, including woollen goods and felt (30%). Special peasant industries are wooden spoons in Semenov, cutlery and locks in Gorbatoev, spindles in Balakhna, fancy boxes in Makaryev, and furs and leather goods.

NIZHNE-TAGILSK, popularly known as Tagil, a Russian town in the Uralsk area, in 57° 27' N., 59° 54' E. Pop. (1926) 38,828. It is situated in a valley on the eastern slope of the Ural Mountains, within a few miles of the place where the Tagil escapes to the lowlands to join the Tura, a tributary of the Tobol. The southern part of this valley is occupied by the upper Tagil, and its northern portion by the upper Tura, from which the Tagil is separated by a low watershed. The town is connected by railway (the first in Siberia) with Perm and Sverdlovsk, and with mines to the east and west. It was founded in 1725 by the Russian mine-owner Demidov. Nizhne-Tagilsk is a central foundry for iron-mines and other works. Gold, platinum and copper are mined at Nizhne-Tagilsk, and there is a brick-making industry. Wagon works with an output of 5,000 wagons per annum were under construction in 1928.

NIZHNIY NOVGOROD: see NIJNI NOVGOROD.

NOAH appears in Genesis v. 29 as son of Lamech and tenth in descent from Adam. The hazardous attempt of the verse to find an etymology for the name in the Hebrew verb "comfort" is an extract from another tradition, and views Noah as repairing in some measure by his discovery of vine-culture, Gen. ix. 20, the disaster of the curse pronounced upon the ground by Yahweh in consequence of the Fall. The story of the Deluge has Noah for its hero. He is represented as the patriarch who, because of his blameless piety, was chosen by God to perpetuate the human race after his wicked contemporaries had perished in the Flood. He receives a divine warning of the impending disaster, and is instructed to build an ark, in which he and his family are preserved alive. In accordance with God's instructions Noah took into the ark specimens of all animals, from which the stocks might be replenished. The story has close affinities with Babylonian traditions, in which Ut-napishtim plays the part corresponding to that of Noah (see DELUGE). The narrative of Gen. ix. 18-27 belongs to a different cycle, which seems to know nothing of the Flood story. In the latter Noah's sons are married, and their wives accompany them in the ark; but in this narrative they would seem to be unmarried, living in the tent with their father; nor does the shameless drunkenness of Noah accord well with the character of the pious hero of the Flood story. Three different motives may be traced in Gen. ix. 18-27: first the passage explains to whom agriculture, and in particular the culture of the vine, was due; secondly it attempts to provide in the persons of Noah's three sons, Shem, Ham and Japheth, ancestors for three of the races of mankind, and to account in some degree for their historic relations; in the third place, by its censure of Ham—for whom it is almost certain that Canaan stood in the original text—it rebukes the licentious Canaanite civilization.

(W. L. W.)

NOAILLES, the name of a great French family, derived from the castle of Noailles in the territory of Ayen, between Brive and Turenne in the Limousin, and claiming to date back to the 11th century. In the 16th century, its head, ANTOINE de Noailles

(1504-1562), became admiral of France, and was ambassador in England during three important years, 1553-1556, maintaining a gallant but unsuccessful rivalry with the Spanish ambassador, Simon Renard. HENRI (1554-1623), son of Antoine, was a commander in the religious wars, and was made comte d'Ayen by Henry IV. in 1593. ANNE (d. 1678), the grandson of the first count, played an important part in the Fronde and the early years of the reign of Louis XIV., became captain-general of the newly won province of Roussillon, and in 1663 was made duc d'Ayen, and peer of France.

ADRIEN MAURICE (1678-1766), the third duke, served in the wars of Louis XV. in Italy and Germany, and became a marshal in 1734. In the war of the Austrian succession he was beaten by the English at the battle of Dettingen in 1743. He married Françoise d'Aubigné, a niece of Madame de Maintenon, and two of his sons became marshals of France. The elder, LOUIS (1713-1793), who bore the title of duc d'Ayen till his father's death in 1766, when he became duc de Noailles, served in most of the wars of the 18th century, and was made a marshal in 1775. He refused to emigrate during the Revolution and died in Aug. 1793, before the Terror reached its height. On the 4th Thermidor (July 22) the aged duchesse de Noailles was executed with her daughter-in-law, the duchesse d'Ayen, and her granddaughter, the vicomtesse de Noailles. JEAN PAUL FRANÇOIS (1739-1824), the fifth duke, was in the army, but his tastes were scientific, and for his eminence as a chemist he was elected a member of the Academy of Sciences in 1777. He became duc d'Ayen in 1766 on his grandfather's death, and duc de Noailles on his father's in 1793. He lived in Switzerland from 1792 until the Restoration in 1814, when he took his seat as a peer of France.

One other branch of the family deserves notice. PHILIPPE (1715-1794), comte de Noailles, afterwards duc de Mouchy, a younger brother of the fourth duke, served at Minden and in other campaigns, and was made a marshal on the same day as his brother. He was long in great favour at court, and his wife was first lady of honour to Marie Antoinette, and was nicknamed by her Madame Étiquette. This court favour brought down punishment in the days of the Revolution, and the old marshal and his wife were guillotined on June 27, 1794.

PHILIPPE LOUIS MARC ANTOINE, duke of Noailles and prince of Poix (1752-1819), was born on Nov. 21, 1752. In 1789 he was elected deputy of the States-General by the nobility of the *bailliages* of Amiens and Ham, but was compelled to resign in consequence of a duel with the commander of the Garde Nationale at Versailles. He left the country but returned and took part in the revolution of Aug. 10, 1792, after which he again escaped until 1800. At the Restoration he was brought again into favour and became a peer of France. He died at Paris on Feb. 17, 1819.

LOUIS MARIE (1756-1804), vicomte de Noailles, was the second son of the marshal. He served brilliantly under La Fayette in America, and concluded the capitulation of Yorktown. He was elected to the states-general in 1789. He began the famous "orgie," as Mirabeau called it, on Aug. 4, when all privileges were abolished, and with d'Aiguillon proposed the abolition of titles and liveries in June 1790. When the Revolution became more pronounced he emigrated to America. He accepted a command against the English in San Domingo, under Rochambeau. He made a brilliant defence of the mole St. Nicholas, and escaped with the garrison to Cuba; but in making for Havana his ship was attacked by an English frigate, and after a long engagement he was severely wounded, and died on Jan. 9, 1804.

NOAKHALI, a district and town of British India, in the Chittagong division of eastern Bengal and Assam, the town also known as Sudharam is on a small river channel 10 m. from the sea. The DISTRICT OF NOAKHALI has an area of 1,644 sq.m. It consists of an alluvial tract of mainland together with several islands at the mouth of the Meghna. In general, every homestead is surrounded by a thick grove of betel and coco-nut palms. Rice is the great staple of cultivation. The district is very fertile and is under continuous cultivation. The delta was swept by a storm wave on Oct. 31, 1876, and it is estimated that 100,000 lives were lost. The district is served by the Assam-Bengal railway.

NOBEL, ALFRED BERNHARD (1833–1896), Swedish chemist and engineer, was born at Stockholm on Oct. 21, 1833. On his return to Sweden after a stay in St. Petersburg he devoted himself to the study of explosives, and especially to nitroglycerin. He found that when that body was incorporated with an absorbent, inert substance like *kieselguhr* it became safer and more convenient to manipulate, and this mixture he patented in 1862 as dynamite. He next combined nitro-glycerin with another high explosive, gun-cotton, and obtained a transparent, jelly-like substance, which was a still more powerful explosive than dynamite. Blasting gelatin, as it was called, was patented in 1876. Some 13 years later Nobel produced ballistite, one of the earliest of the nitro-glycerin smokeless powders, and a precursor of cordite. Nobel's claim that his patent covered the latter was the occasion of vigorously contested lawsuits between him and the British Government in 1894 and 1895; the question was complicated, but eventually the courts decided against Nobel. From the manufacture of dynamite and other explosives, and from the exploitation of the Baku oil-fields, he amassed an immense fortune; at his death on Dec. 10, 1896 at San Remo, he left the bulk of it in trust for the establishment of five prizes (*see below*).

NOBEL PRIZES. These are awarded from the Nobel Foundation, a fund established under the will of A. B. Nobel (*q.v.*), who in his will directed that the interest of the bulk of his huge fortune should be "apportioned as follows: one share to the person who shall have made the most important discovery or invention in the domain of physics; one share to the person who shall have made the most important chemical discovery or improvement; one share to the person who shall have made the most important discovery in the domain of physiology or medicine; one share to the person who shall have produced in the field of literature the most distinguished work of an idealist tendency; and, finally, one share to the person who shall have most or best promoted the fraternity of nations and the abolition or diminution of standing armies and the formation and increase of peace congresses. The prizes for physics and chemistry shall be awarded by the Swedish academy of science in Stockholm; the one for physiology or medicine by the Caroline medical institute in Stockholm; the prize for literature by the academy in Stockholm and that for peace by a committee of five persons to be elected by the Norwegian Storting. I declare it to be my express desire that, in the awarding of prizes, no consideration whatever be paid to the nationality of the candidates."

As the will was drawn up by Nobel without legal aid, it was interpreted by a code of statutes, approved by the Swedish Government and consented to by the heirs. The distribution of prizes was begun on Dec. 10, 1901, the anniversary of Nobel's death. The amount of each prize varies with the income from the fund. In 1928 the amount was \$42,060.

The statutes provide for the establishment of Nobel institutes, one for each of the five sections, and one-fourth of the amount which falls to each section from the main fund is deducted for its expenses before prize distribution is made.

Provision is made that any prize may be reserved for one year; if not then distributed, the amounts revert to the main fund, or special reserves for each section. The peace prize has been reserved most frequently and special Nobel institutes have been created from the surplus funds. Another provision is: "The amount allotted to one prize may be divided equally between two works submitted, should each of such works be deemed to merit a prize." In 1904 the peace prize was awarded to the Institute of International Law, which marked the beginning of bestowing a prize upon a society rather than an individual.

The only individual who has received prizes from more than one section is a woman, Mme. Marie Curie, who has received the prize both in physics and chemistry. The British and American prize winners since the establishment have been: *Physics*, British—Lord Rayleigh (1904), J. J. Thomson (1906), W. H. Bragg (1915), W. L. Bragg (1915), Charles G. Barkla (1917), C. T. R. Wilson (1927); American—A. A. Michelson (1907), R. A. Millikan (1923), A. Compton (1927). *Chemistry*, British—Sir Wm. Ramsay (1904), Sir E. Rutherford (1908), F. Soddy (1921),

F. W. Aston (1922); American—T. W. Richards (1914). *Medicine*, British—Sir Ronald Ross (1902), A. V. Hill (1922), F. G. Banting and J. J. R. McLeod (Canada, 1923); American—A. Carrel (1912). *Literature*, British—R. Kipling (1907), Rabindranath Tagore (Indian, 1913), W. B. Yeats (Irish, 1923), G. Bernard Shaw (1925); American—none. *Peace*, British—Sir W. R. Cremer (1903), Sir A. Chamberlain (1925); American—T. Roosevelt (1906), Elihu Root (1912), Woodrow Wilson (1919), C. G. Dawes (1925). The awards announced in Dec. 1928 were: in physics, award reserved; in chemistry the award reserved from 1927 to Heinrich Wieland, for 1928 to Adolf Windaus; in medicine to Dr. Charles Nicolle of the Pasteur institute; in literature for 1927, Henri Bergson, and for 1928, Sigrid Undset; the peace prize for 1928 was reserved.

See Nobelstiftelsen, The Nobel Foundation Code of Statutes (Stockholm, 1901); A. R. Marble, *The Nobel Prize-winners in Literature* (1925).

NOBILE, UMBERTO (1885–), Italian explorer, was born at Avellino. He was educated at the Naples Polytechnic, and became an engineer. Later he obtained a post in the railway department of the ministry of public works in Rome. As a result of plans for airship construction made by him, he was given a post in the war ministry, and was entrusted with the construction of the airship "Roma," with the assistance of Uselli. His airship, the "Norge," was used for the flight with Amundsen to the Pole, in May 1926, when a landing was made at Teller, Alaska. Nobile was promoted to the rank of general, was made a marquis and appointed a professor at the Naples Technical College. A controversy subsequently arose both with Lincoln Ellsworth and Amundsen with reference to the credit for leadership of the expedition. In May 1928 Nobile set out on a second expedition to the North Pole, in the airship "Italia," but shortly after passing over the Pole on May 24, 1928, the airship crashed on the ice (May 25). The gondola and main cabin were smashed, and the 10 men in them thrown out on the ice. Seven of the party were carried away with the balloon, and were never traced. On May 30, three of the party, Malmgren, Mariano and Zappi, set out on foot, hoping to reach Cape North. After their departure on June 9, the remainder of the expedition managed to establish wireless communications with rescue parties, and on June 23 Nobile was rescued by an aeroplane belonging to the Swedish expedition. The six men remaining with the party were rescued. Mariano and Zappi were located on July 12, by the Russian airman Tchuknovsky. Malmgren (*q.v.*) died near Brock Island.

Nobile was found responsible for the loss of the "Italia" by an Italian Commission of Enquiry in 1929 and resigned his rank in consequence.

NOBLE, SIR ANDREW, 1ST BART., CR. 1902 (1832–1915), British physicist and artilleryman, was born at Greenock on Sept. 15, 1832, and was educated at Edinburgh Academy and at the Royal Military Academy, Woolwich. In 1849 he entered the Royal Artillery, attaining the rank of captain in 1855, and in 1857 became secretary to the Royal Artillery Institution. About this time the question of the supersession of the old smooth-bores by rifled guns was coming to the fore, and on the appointment of the select committee on rifled cannon in 1858 to report on the matter, he was chosen its secretary. He devised an ingenious method for comparing the probable accuracy of the shooting attainable with each type of gun. In 1859 he was appointed assistant-inspector of artillery, and in the following year he became a member of the ordnance select committee and of the committee on explosives, serving on the latter until its dissolution 20 years later. About the same time he was prevailed upon by Sir William, afterwards Lord, Armstrong to leave the public service and take up a post at Elswick. Here he became chairman of the company. About 1862 he invented his chronoscope for the measurement of exceedingly small intervals of time, and began to apply it in ballistic experiments for ascertaining the velocity with which the shot moves along the barrel of a gun with different powders and different charges. Then he joined Sir Frederick Abel in a classical research on "fired gunpowder," the experimental work being largely carried on at Elswick. The conclusions they reached

had a great effect on the progress of gunnery, for they showed increased pressures in the gun. Noble advocated nitro or "smokeless" powders, and the Elswick works provided facilities, which were not offered by the Government, for the necessary experimental work of the committee on cordite. Noble was the recipient of many honours. His scientific papers were collected as *Artillery and Explosives* (1906). He died in Argyllshire on Oct. 22, 1915.

NOCERA INFERIORE, formerly *NOCERA DEI PAGANI* (anc. city *Nuceria Alfaterna*, town and episcopal see, Campania, Italy, province of Salerno, at the foot of Monte Albino, 23 m. E.S.E. of Naples by rail, 135 ft. above sea-level. Pop. (1921) 22,504 (town); 24,404 (commune). In the old castle Helena, widow of Manfred, died after the battle of Benevento. Two miles east near the village of Nocera Superiore is the circular domed church of Sta Maria Maggiore, dating from the 4th century.

The city early became an episcopal see, and in the 12th century it sided with Innocent II. against Roger of Sicily, suffering severely for its choice. A colony of Saracens introduced by Frederick II. probably gave rise to the epithet ("of the pagans"), as well as to the town of Pagani, about 1 m. west.

NOCTILUCA, the organism which is the main and most usual cause of the "phosphorescence" of the sea. *Noctiluca* is a protozoan reaching a length of a millimetre, i.e., it may be visible to the naked eye. (See PROTOZOA; PHOSPHORESCENCE, ANIMAL.)

NOCTURN or **NOCTURNE**, in music a term meaning "right-piece," a dreamy, soft, musical composition. The name is almost inseparably connected with John Field (q.v.), who invented this form, although Chopin is also well-known as a nocturne-writer. The nocturne is usually associated with the pianoforte, especially in Northern Europe. The underlying idea of this type of composition is that the mood becomes of a more melancholy nature, as though to present definitely the vision of night. "Notturmo" (Italian) was used originally as a term for a type of serenade (q.v.). This was employed with signal success by Mozart in his three-movement opus for strings and two horns.

In the form "nocturn" the word is used as a form of *Nocturnae* or *Watches of the night*. On Sundays there are three nocturns; the first contains 12 psalms and the two others contain three psalms each. A lesson is read at the end of each nocturn and each lesson is divided into three portions.

NODDY, the name applied to a sea-bird, *Anous stolidus*, one of the Terns (q.v.), from its showing so little fear of man as to be accounted stupid. It is heavier in flight than most terns, with shorter wings and less forked tail. The plumage is of a uniform sooty hue, except the light grey crown of the head. The noddy is very generally distributed throughout tropical and sub-tropical oceans. It breeds in astounding numbers, on low cays and coral-islets, making a nest composed of sea-weed or small twigs. Other birds of the same genus are: the darker Pacific noddy (*A. s. sidgwayi*), the still darker Galapagos noddy (*A. s. galapagensis*) and the white-headed noddy (*A. leucocapillus*). There is also the white noddy (*Gygis alba*).

See J. B. Watson in *Papers from the Tortugas Laboratory*, No. 8.

NODE [Lat. *nodus*, a loop], in astronomy, one of two opposite points at which a heavenly body passes through the principal co-ordinate plane to which its motion is referred. In the case of the heavenly bodies this plane is commonly that of the ecliptic, but, in special cases, the plane through the origin parallel to the earth's equator or the plane of a planet's orbit is used. The ascending node is that at which the body moves from the south or negative towards the north or positive side of the plane. The moon's nodes are the points in which its path intercepts the plane of the ecliptic. In the geometry of curves, a node is the name given to the loop formed by a continuous curve crossing itself, the point of crossing is termed a "double point," and at it there are two non-coincident tangents to the curve; the remaining species of double points, termed "acnode," "spinode" or "cusp," admits of two coincident tangents (see CURVE).

NODIER, CHARLES (1780-1844), French author, was born at Besançon. His father, on the outbreak of the Revolution, was

appointed mayor of Besançon and Charles is said to have been a member of the Jacobin club when he could not have been more than 12 years old. He was sent to Strasbourg, where he lived in the house of Eulogius Schneider, the notorious Jacobin governor of Alsace, but a good Greek scholar. He became librarian in his native town, but his exertions in the cause of suspected persons brought him under suspicion. For a skit on Napoleon, in 1803, he was imprisoned for some months. He then lived a very unsettled life at Besançon, Dôle, where he married, and in other places in the Jura. During these wanderings he wrote *Le Peintre de Salzbouurg, journal des émotions d'un coeur souffrant, suivi des Méditations du cloître* (1803). He continued to lead an unsettled life until in 1824 he was appointed to the librarianship of the Bibliothèque de l' Arsenal. He was elected a member of the Academy in 1833, and died on Jan. 27, 1844. During his 20 years at the arsenal he was able to supply a centre and rallying place to a knot of young literary men of greater individual talent than himself—the so-called Romantics of 1830—and to colour their tastes and work very decidedly with his own predilections. Victor Hugo, Alfred de Musset and Sainte-Beuve all acknowledged their obligations to him. He was a passionate admirer of Goethe and of Shakespeare. The best examples of his work are to be found in the volume entitled *Mélanges tirés d'une petite bibliothèque*.

His *Description raisonnée d'une jolie collection de livres* (1844), which is a catalogue of the books in his library, contains a life by Francis Wey and a complete bibliography of his numerous works. See also Sainte-Beuve, *Portraits littéraires*, vol. ii.; G. Brandes, *Main Currents in 19th Century Literature* (1871); Prosper Mérimée, *Portraits historiques et littéraires* (1874); A. Estignard, *Correspondence inédite de Charles Nodier, 1796-1844* (1876); J. Vodoz, *La Fée aux Miettes, Essai sur le rôle du subconscient dans l'oeuvre de Charles Nodier* (1925).

NŌ DRAMA. In Japan in the beginning of the 15th century, the *Saru-gaku* (lit. "monkey music," consisting of juggling feats and comic remarks with actions to suit) of Yamato Province was revolutionized by Kan-nami Kiyotsugu and his son Se-ami Motokiyo, and what is now known as *nō-gaku*, or *nō* music or drama resulted. Not only did these two geniuses, under the encouraging patronage of the Shogun Yoshimasa, build on what was best in their own *Saru-gaku*, but they drew freely from *Den-gaku* (lit. "rice-field music") which had much in common with the *Saru-gaku*. What was graceful in them was ennobled to profundity in the *nō*, while their comical elements developed into *kyogen* (comic performance) usually given in conjunction with the *nō*.

The *nō-gaku* constituted the principal form of entertainment among aristocrats and the warrior class in the feudal Japan. It was sometimes given in the presence of the emperors, and there prevailed a custom for a time to invite the common people to the performances given in commemoration of some happy events by the Tokugawa Shoguns, who used the *nō* on all ceremonial occasions.

Staging.—The *nō* is performed on a wooden stage built above the ground, the regular size of which now is 18 ft. square, open on three sides, with a narrow extension on one side for the singers, and another on the back of the stage for the musicians and attendants. To that rear extension is attached aslant a passage called *hashigakari* (a bridge). The players appear from under the curtain at the one end of which the passage slightly slopes down. The stage, too, is very slightly tilted to the front. For acoustic purposes, big ceramic jars are placed, generally seven under the stage and two or more under the passage according to its length. Three pine saplings are planted at intervals along the front of the bridge. The wooden wall called *kagami-ita* (mirror board) on the back of the rear extension, forming a background to the stage, is always decorated with a painting of a pine tree, and the narrow panel adjoining it on the side with that of bamboo. These paintings, together with the saplings, may be taken to indicate that originally the *nō* was performed in the woods.

Character of the Nō Pieces.—The *nō* pieces, which number more than 250, are classified into five groups for convenience: (1) *waki-nō* (pieces in which *waki*, the secondary character,

MASKS WORN IN THE NO PERFORMANCES

1. "Okina" used by the principal character in *Okina*. Hōshō
2. "Masojiro" used by a young woman character. Kongo family in Kyoto
3. "Sanko" used for elderly man of common class. Kongo
4. "Daikujō" used for an elderly man of fierce character. Marquis Maeda's collection
5. "Zō" used for young woman. Marquis Maeda's collection
6. "Hannya" for woman demon. Marquis Maeda's collection
7. "Yamamba" used by the heroine in *Yamamba*. Marquis Maeda's collection

assume's preponderance in the play) generally dealing with Shinto or Buddhist deities; (2) *Shura-mono*, which commonly deals with ghosts of warriors; (3) *Kasura-mono*, with noble ladies playing the main parts; (4) *Genzai-mono*, or present-day piece, dealing with love, insanity and other manifestations of human nature; (5) pieces dealing with demons or goblins as subjects, or those of congratulatory nature with gay and joyous elements. For each programme of *nô* performance, which generally lasts a whole day, one from each of the above-mentioned five classes is given in the order mentioned, with a *kyogen* between each and generally a dance in an ordinary dress in addition. The whole programme is preceded by a piece called "Okina," which is held in special reverence, the person acting its chief character, Okina, symbolizing the radiant sun-goddess.

Construction of *Nô* Pieces.—The construction of the *nô* piece, though by no means uniform, is generally as follows. A *waki* (the secondary rôle), generally a monk or a minister of State, first appears and tells who he is. Then he walks a while, singing, suggesting that he is travelling. Coming to a standstill, he announces his arrival at a certain famous spot and takes his place by the post at the front right-hand corner facing the stage. Then the *maya jite* (the principal character in the first appearance) comes in the form of a farmer, fisherman or priest, etc., describing the scenery of the place, or speaking to *waki* resting at the post. The *waki* questions him, and the *maya jite* gives an historical account of the place and of heroes connected with it, or relates the origin of the temple or shrine as the case may require, thus furnishing the audience with a necessary background to the play. The *maya jite* then retires in a hurry. He was in reality no other than a Shinto or Buddhist deity, or a ghost of a warrior, in disguise. While *waki* is startled by the sudden disappearance, there come to the stage common farmers or wood-choppers and give in plain language, spoken more or less in the ordinary way, all detailed information concerning the place, generally reiterating what was already given in intonation, and retire. This allows a necessary time for the principal character to change for reappearance. While waiting, the *waki* sings, indicating a lapse of time. When it comes to an end, the *nochi jite* (the principal character in the latter appearance) in proper form and attire as a Shinto or Buddhist deity, or a spirit of a hero, comes to the stage and dances as if in a night stroll, revealing some spiritual attributes. In words and in action he recounts his bravery, his death struggle, or his suffering in the underworld, asking for the prayer of the *waki* for the peaceful repose of his soul. The *shite* tells his story as he performs, or he merely dances without any intonation. Generally there is a chorus who intonate either alone or with the performers.

Music and Accessories.—Generally several persons sitting on the side extension sing either in chorus, by themselves, or together with the performer. The musicians on the rear extension consist ordinarily of a player each on the transverse flute, the *tsuzumi* (small drum struck with tips of fingers over the shoulder), the *ôkawa* (a slightly larger drum struck on the knee also with tips of fingers) and the drum beaten with two sticks.

The accessories used on the stage in connection with the play are very simple. A fan is much in evidence in the dance (see FANS), the studied use of which is very effective with the manipulation of big sleeves. Costumes used in the *nô* are marvels of textile fabrics, refined taste being revealed in bold yet harmonious designs and colours. Above all, the mask to be worn by the principal character (*shite*) and the assistant (*shite-zure*) is a very important part of the *nô* performance (see MASKS). There have been great masters among carvers of *nô* masks in the feudal Japan whose works still remain in a large number.

Main Schools.—Ever since the great reformation at the beginning of the 15th century, the *nô* has had four main acknowledged schools or houses: Kwanze, Komparu, Hôshô and Kongô, all of which are still thriving. Later, another school, Kita won official recognition, while still another, Umewaka, also has many followers, the variation upheld by each school being but slight. On the whole, the *nô* performance may well be compared to a masterful oriental picture in black monochrome, both being

guided by highly idealistic aims and with artistic aspirations with many points in common, possessing alike great impelling qualities that thrill the devotee and weary the uninitiated. It has greatly influenced the Japanese stage and ordinary forms of dance known as *mai*, or *odori*, and it is bound to continue to do so. (See THEATRE; JAPANESE ART; PANTOMIME.)

NOEGGERATH, JOHANN JACOB (1788–1877), German mineralogist and geologist, was born at Bonn on Oct. 10, 1788. In 1814–15 he became commissioner of mines for some of the Rhine Provinces, and in 1818 professor of mineralogy and afterwards professor of geology, director of the museum of natural history and chief of the mining department in the university at Bonn. He obtained a very fine collection of minerals for the museum and achieved a wide reputation among mining engineers. The Carboniferous plant *Noeggerathia*, allied to the *Zamia* and cycads, was named after him. He died at Bonn on Sept. 13, 1877.

The following are his more important publications: *Über aufrecht im Gebirgsgestein eingeschlossene fossile Baumstämme und andere Vegetabilien* (1819–21); *Das Gebirge in Rheinland-Westphalen, nach mineralogischem und chemischem Bezüge* (4 vols., 1822–26); *Die Entstehung der Erde* (1843); and *Der Laacher See und seine vulkanischen Umgebungen* (1870).

NOEL, RODEN BERKELEY WRIOTHESLEY (1834–1894), English poet, son of Noel, Lord Barham, afterwards earl of Gainsborough, was born on Aug. 27, 1834. He was educated at Trinity college, Cambridge, and spent two years in the East. His works include *A Little Child's Monument* (1881), *Behind the Veil, and other Poems* (1863), *Beatrice, and other Poems* (1868), *The Red Flag* (1872), *Livingstone in Africa* (1874), *Songs of the Heights and Depths* (1885), *A Modern Faust, and other Poems* (1888), *Poor People's Christmas* (1890) and *My Sea, and other Poems* (1896). Roden Noel's versification was unequal and sometimes harsh, but he has a genuine feeling for nature, and the work is permeated by philosophic thought. He died at Mainz, on May 26, 1894.

His *Collected Poems* were edited (1902) by his sister, Victoria Buxton, with a notice by J. Addington Symonds.

NOGALES, a city on the southern boundary of Arizona, U.S.A., adjoining Nogales, Mexico (*q.v.*); a port of entry, headquarters of the Arizona customs district, and the county seat of Santa Cruz county. It is the southern terminus of Federal highway 89, and is served by the Southern Pacific railroad. The population was 5,199 in 1920 (49% foreign-born white) and was estimated locally at 6,500 in 1928. The international boundary is a barbed-wire fence down the middle of the main street of the two cities. Nogales has an altitude of 3,869 ft., and is surrounded by the Patagonia mountains, and is the site of Camp Stephen D. Little, an infantry post. The commerce of the customs district with Mexico in 1927 amounted to \$25,057,175 (58% imports). Stock-raising and mining (lead, silver and copper) are the leading occupations of the region. The old Spanish mission of Turnacacori is 18 m. N. In 1880 Nogales was a trading post. In 1893 it was incorporated as a town, and in 1919 as a city.

NOGARET, GUILLAUME DE (d. 1313), councillor and keeper of the seal to Philip IV. of France, was born between 1260 and 1270, the son of a citizen of Toulouse. The family took its name from a small property near Saint Félix de Caramon. In 1291 Guillaume was professor of jurisprudence at the University of Montpellier, and in 1296 became a member of the Curia Regis at Paris. His name is connected with Philip IV.'s quarrel with Pope Boniface VIII. (*q.v.*), to whom Nogaret was sent with an embassy in 1300. In Feb. 1303 Nogaret persuaded Philip to agree to a plan to seize Boniface and bring him to a council in France which should depose him. Nogaret went to Italy, and captured Boniface, with the help of Sciarra Colonna, but was eventually defeated by a rising of the townsmen of Anagni. The pope's death at Rome, on Oct. 11, saved Nogaret. The election of the timid Benedict XI. was the beginning of that triumph of France which

lasted through the Avignon captivity. Early in 1304 Nogaret was sent by Philip to demand from Benedict XI. absolution for the enemies of Boniface VIII. Benedict refused to receive Nogaret, and he was excepted from the general absolution of May 13, 1304, and issued against him and his associates the bull *Flagitiosum scelus*. A Frenchman, Bernard de Got (Clement V.) was elected pope on Benedict's death in 1304. The threat of proceedings against the memory of Boniface had forced Clement to absolve Nogaret. When Philip proposed an enquiry into the condition of the Templars as a preliminary to their arrest and the seizure of their property, Nogaret persuaded the renegade members to give evidence against their fellows. Clement's ineffective resistance still further delayed an agreement with Philip. Nogaret became keeper of the seal in 1307, and his talents as *advocatus diaboli* had further scope in the trial (1308-13) of Guichard, bishop of Troyes, charged with crimes which included witchcraft and incontinence. Clement feared similar proceedings against Boniface, and gave Nogaret absolution on April 27, 1311.

See E. Renan in *Histoire littéraire de la France*, xxvii. 233; R. Holzmänn, *Wilhelm von Nogaret* (Freiburg, 1898). For the sources consult Dom Bouquet, *Recueil de historiens des Gaules et de la France*, vols. xx.-xxiii.; *Annales regis Edwardi primi* in Rishanger ("Rolls" series), pp. 483-491, which gives the fullest account of the affair at Anagni.

NOGENT-SUR-MARNE, a suburb 11 kilometres east of Notre Dame de Paris, in the department of Seine, on a hill on the right bank of the Marne. Pop. (1926) 19,331. The Eastern railway here crosses the Marne valley by a viaduct 875 yd. in length. Nogent has a Gothic church, with a tower of the Romanesque period, in front of which there is a monument to Watteau, who died here in 1721. Chemical products are manufactured. The fine situation of the town gained it the name of Beauté, and Charles V. built a château here (demolished in the 18th century) which was presented by Charles VII. to Agnes Sorel with the title of Dame de Beauté. An island in the Marne to the south of the town is still known as the Île de Beauté. The increase of population here in recent years is very notable.

NOGUCHI, HIDEYO (1876-1928), Japanese bacteriologist, was born in Inawashiro, Yama, Fukushima, Japan, Nov. 24, 1876. He received the degree of M.D. in 1897 from the Tokyo Medical college and subsequently did post-graduate work in the United States and Europe, becoming connected with the Rockefeller Institute for Medical Research in New York in 1904. He was the first to obtain pure cultures of the spirochaete of syphilis and to establish the syphilitic nature of general paralysis and *tabes dorsalis* by demonstrating the organism in the cells of the central nervous system of persons dying of these diseases. He did considerable work on the analysis of the Wassermann reaction for the diagnosis of syphilis and devised a skin test for syphilis and a method for the detection of syphilitic and other pathological conditions in the spinal fluid. One of the first to recognize the germicidal properties of certain compounds of unsaturated fatty acids for acid-fast micro-organisms, e.g., the tubercle bacillus, he discovered the parasite of yellow fever in 1918 and prepared a prophylactic vaccine and a curative serum for combating this disease. He also isolated the parasite of Oroya fever and *Verruga peruviana*. During his investigations he contracted yellow fever and died in British West Africa on May 21, 1928.

His published works include *Snake Venoms* (1909), *Serum Diagnosis of Syphilis and Luetin Reaction* (1910) and *Laboratory Diagnosis of Syphilis* (1923).

NOISE AND ITS CONTROL. No rigid definition of noise is possible. By analogy with "dirt," it has been called "sound out of place," and it is usually a medley of individual sounds. For measuring noise the instrument most widely used, especially in America, is the audiometer devised by the Bell Telephone Laboratories, in which the noise is matched in the observer's ear against a standard noise produced by the instrument. In England measurements have been made with an electric audiometer invented by Mr. A. M. Low. "Noise units" have been used to express such measurements but most of these are of comparative value only. For scientific purposes the units should be purely physical; for example, to dynes per square centimeter.

A comprehensive survey of the intensity and sources of city

noise was made in 1925 and 1926 in New York city. Partial surveys have been made in London, Chicago, Boston, Washington and other cities. The noisiest normal street corner so far discovered anywhere in the world is the corner of Sixth avenue and Thirty-Fourth street in New York city; an intersection of three main highways, three surface car lines and a double-track line of the elevated railway. At this corner the noise intensity is sufficient to make the normal individual about two-thirds deaf. Noise intensity in exceptional places, like railway subways or noisy factories, may be twice or three times greater than this. On the average busy street of an American city the day-time noise is sufficient to render the normal individual one-fourth to one-third deaf. The ebb and flow of noise from hour to hour during the 24-hour day parallels precisely the increase and decrease of vehicular traffic on the streets. In physical units the New York city street noise was found to vary between 0.007 dynes per square centimeter and 20 dynes, averaging about 5 dynes.

Approximately 40% of the noise could be traced to the automobile trucks used for commercial deliveries; 25% to the elevated railway, and 20% to the surface cars. The remaining 15% was supplied by private automobiles, taxicabs, automobile horns, horse-drawn vehicles, riveting and excavating machines, alarm signals of the fire and police departments and other occasional noise-producers. At no place on city streets do human speech and human feet make measurable contributions to the noise. At windows street noise decreases with height, but much less so than would be expected from the physical law of attenuation of sounds in the open air, the discrepancy being due to reflection of the noise between the buildings on the two sides of the street.

The usual assumption that noise is harmful to man is by no means proved. Noise is known to affect the human heart beat as well as the rate at which heat energy is set free in the human body, but the details of these effects have not been studied. Most individuals accustom themselves to living or working in noisy surroundings and only nervous individuals who fail to make this adjustment suffer harmful effects. It has been urged that the greater use of bodily energy in noisy surroundings may cause bodily ills. Searching investigations of these problems are now (1929) under way in several American laboratories of psychology. Contrary to the usual opinion, there is no dependable evidence that life or work in noisy places decreases the acuteness of hearing, except during the first few minutes after the noise ceases.

Much noise could be prevented by denying use of the streets to vehicles improperly cared for, and which rattle or squeak, especially automobile trucks; also by preventing loose, rattling parts on surface cars and by removing loose or wide crossings in the rails of street railways and by restricting the blowing of horns. It is possible that the average street noise of a city could be reduced at least one half by adequate enforcement of such regulations. The construction of noise-proof rooms or noise-proof houses is possible on well-known principles of architectural acoustics but is too expensive for general use. (E. E. F.)

Law.—In law noise may be defined as an excessive, offensive, persistent or startling sound. By the common law of England freedom from noise is essential to the full enjoyment of a dwelling house, and acts which affect that enjoyment may be actionable as nuisances. But it has been laid down that a nuisance by noise, supposing malice to be out of the question, is emphatically a question of degree (*Gaunt v. Finney*, 1872, 8 Ch. Ap. 8). The noise must be exceptional and unreasonable. The ringing of bells, building operations, vibration of machinery, fireworks, bands, a circus, merry-go-rounds, collecting disorderly crowds, dancing, singing, etc., have been held under certain circumstances to constitute nuisances so as to interfere with quiet and comfort, and have been restrained by injunction. Noise occasioned by the frequent repetition of street cries is frequently the subject of local by-laws, which impose penalties for infringement.

NOLA, an ancient city and see of Campania, Italy, province of Naples, pleasantly situated in the plain between Mount Vesuvius and Apennines, 16½ m. E.N.E. of Naples by rail, 121 ft. above sea-level. Pop. (1921) 8,333 (town); 15,672 (commune). There is an ancient Gothic cathedral with its lofty tower. July

26 is devoted to a great festival in honour of St. Paulinus (*q.v.*). The church erected by him in honour of St. Felix in the 4th century is extant in part. Giordano Bruno (*q.v.*) was born at Nola in 1580. The Etruscans were in Nola about 500 B.C. They helped Neapolis against the Roman invasion (328 B.C.). The Romans made themselves masters of it in 313 B.C. In the Social War it was betrayed into the hands of the Samnites. Sulla in 80 B.C. subjected it with the rest of Samnium. Seven years later it was stormed by Spartacus. Nola became a Roman colony under Augustus, who died there. It was sacked by Genseric in 455, by the Saracens in 806 and 904, captured by Manfred in the 13th century, and damaged by earthquakes in the 15th and 16th.

Nola lay on the Via Popillia from Capua to Nuceria and the south, and a branch road ran from it to Abella and Abellinum. While independent it issued an important series of coins, and in luxury it vied with Capua. Its territory was very fertile. A large number of vases of Greek style were manufactured here of pale yellow clay with shining black glaze, decorated with skilfully drawn red figures. Of the ancient city, numerous ruins, an amphitheatre, still recognizable, a theatre, a temple of Augustus, etc., existed in the 16th century. The neighbourhood was divided into pagi or villages, the names of some of which are preserved to us (Pagus Agrifanus, Capriculanus, Lanitanus). (T. A.)

NÖLDEKE, THEODOR (1836–), German Semitic scholar, was born at Harburg on March 2, 1836, and studied at Göttingen, Vienna, Leyden and Berlin. In 1859 his history of the Koran won for him the prize of the French Académie des Inscriptions, and he rewrote it in German with additions (*Geschichte des Korans*, Göttingen, 1860). He has taught at Göttingen (1861), Kiel (1868) and Strassburg (1872). In the main his work deals with Semitic languages, and the history and civilization of Islam.

Among his best-known works are: *Das Leben Mohammeds* (1863); *Beiträge zur Kenntnis der Poesie der alten Araber* (1864); *Die alttestamentliche Literatur* (1868); *Untersuchungen zur Kritik des Alten Testaments* (1869); *Zur Grammatik des klassischen Arabisch* (1896); *Fünf Mo'allagat, übersetzt und erklärt* (1899–1901); *Beiträge zur semitischen Sprachwissenschaft* (1904); *Neue Beiträge zur semitischen Sprachwissenschaft* (1910). In the *Encyclopædia Britannica*, he wrote on Persia, the Koran and other subjects.

NOLLEKENS, JOSEPH (1737–1823) British sculptor, was born on Aug. 11, 1737, in Dean Street, Soho, London, where his father, a native of Antwerp, the "old Nollekens" of Horace Walpole, was a painter of some repute. In his thirteenth year he entered the studio of the sculptor Peter Scheemakers for drawing and modelling. In 1760 he went to Rome, and his marble bas-relief, "Timoclea before Alexander," brought him a prize of fifty guineas from the Society of Arts in 1762. Garrick and Sterne were among the first English visitors who sat to him for busts; another important piece belonging to this early period is the "Mercury and Venus chiding Cupid." On his return to England he became an associate of the Royal Academy (1771), and in 1772 a member. By this time he had become known to George III., whose bust he shortly afterwards executed, and henceforward, until about 1816, he was the most fashionable portrait sculptor of his day. He himself thought highly of his early portrait of Sterne. Others were those of Pitt, Fox, the prince of Wales (afterwards George IV.), Canning, Perceval, Benjamin West and Lords Castlereagh, Aberdeen, Erskine, Egremont and Liverpool. Among his numerous marble groups and statues are the "Bacchus," "Venus taking off her Sandal," "Hope leaning on an Urn," and (his own favourite performance) "Venus anointing Herself." His work is remarkable for delicacy of workmanship, but deficient in vigour and originality. A later characteristic of Nollekens was his miserliness. He died in London on April 23, 1823, leaving a large fortune.

NOLLE PROSEQUI, a term of English law now only used of a stay of proceedings by indictment or by information entered by the attorney general. The *nolle prosequi* is a matter purely for his discretion, and will not be granted unless very good ground be shown for his interference. The object of it generally is to obtain a stay of proceedings against an accomplice in order to procure his evidence. This object is, however, more usually effected by the prosecution offering no evidence and the judge

directing an acquittal.

In the United States the attorney general has not always the same discretion with which English law invests him. Although in some States the prosecuting officer may enter a *nolle prosequi* at his discretion, in others the leave of the court must be obtained.

NOMADS, "wanderers," primitive pastoral people who have no settled territory.

Nomads seem to exist in every large territory. Some, like the gypsies (*q.v.*), becoming international. There are Asiatic nomads of all types, the chief being the Mongols whose nomadism became highly specialized. The Basques (*q.v.*) are generally supposed to have been nomads from a remote corner of Asia and the report that shifting colonies of *Euskeru* stock are to this day found in South America supports this view.

Northern Asia is the wide home of numerous wandering tribes whose very names have only recently been recorded. These tribes have a definite relation with the settled peoples over whose territory they roam, as is the case with the African nomads (*see below*). Indo-China (*q.v.*), has its nomad peoples, and South-west China is an area over which several nomad stocks wander. The change from nomadism to a settled state of occupation in well-defined areas is rare but not unknown.

Nomads proper are those who roam over different territories in actual quest of sustenance; as the name implies, they are pastoral people depending on grazing for their animals and edible roots and fruits for themselves. (*See BUSHMEN.*) These nomads have extraordinary powers of adaptability and can support long periods of hunger. The Australian aborigines are sufficiently skilled in woodcraft to trap animals by simply stealing upon them quietly and using the most primitive weapons. The pampas Indians are horseback nomads and wander to and fro over large tracts of territory.

The Bedawin (Bedouins) or Arabs of the desert are among the most familiar of all pastoral nomads, and their nomadism has no known beginning. In times of drought and food shortage such nomads as these and the Hottentots (*q.v.*), are compelled to raid their agricultural settled neighbours. The Kirghiz, an Altai people, are the prominent nomads of Central Asia and their ballads tell of their love of wandering and their passion for their horses, their only tangible possessions.

In recent years much attention has been directed to the nomads of East Africa, as it is believed that from these sprang the original individual peoples of Africa. Some of these nomads are pygmies.

It is probable that at one time they all spoke a distinct language and that many still preserve their own language, while using the language of the tribes among whom they reside. The pygmies of the upper Welle speak the Mbuba language in a manner markedly different from the Mbuba pronunciation, substituting for certain consonants a curious gasp or hiatus almost approximating to a click. The Sanya of north-east Kenya and certain of the Watta are also said to use clicks. The Sandawe (*q.v.*) of Tanganyika Territory, whose skulls possess distinctly Hottentot characters, retain the typical Bushman clicks and gutturals. Rarely has the tribal name been ascertained, the different nomadic groups being called by the names bestowed on them by neighbouring tribes, but the persistence of some of these appellations is remarkable. Some form of the name Twa is widespread among the Bantu: thus the Bushmen of South Africa are known to their neighbours as Abatoa and Batwa is common throughout the Congo and Uganda. The word is said to mean "Bushdwellers," and is probably unconnected with the Watta of southern Abyssinia which is derived from an old Cushitic root meaning "Wanderers." Aka is a name, given to geographically distinct groups of nomads.

In the mountainous forest country of south-west Uganda we find semi-pygmy hunters known as Batwa, and the name reappears on the upper slopes of mount Elgon at an altitude of from 9,000–11,000 ft., where they build earth-roofed huts and live principally on rats, other small mammals and honey.

The Sanya and Choni, hunting tribes living on the banks of the Sabaki and the Tana in Kenya, are also known as Watta to the Galla. They are similar to the Boni of Jubaland, and together with the Midgan and the Sandawe, who also practise circumcision.

are the only nomad communities who practice clitoridectomy.

The Doko pygmies were first described in 1842 by Sir W. C. Harris and later by Borelli and Donaldson Smith, and Rigby also in 1842 reported from hearsay evidence the existence of some pygmies called Berikimo about six weeks inland from Mombasa. The latter are probably the pygmies near Lake Baringo, and the former may be the dwarf Dume who are found in the vicinity of Lake Stephanie. Another group of pygmy nomads exists on the slopes of Mt. Kilimanjaro known as Wapare.

Among the Turkana to the west of Lake Rudolf we find the Teuth, who live on roots and grubs and hunt the smaller mammals, and farther south the Ogiek, known to the Masai as Doroba from the Masai word for tsetse fly to which their arrows are likened, wander over a wide area of forest and bush country between Lake Victoria and the eastern lowlands, maintaining a livelihood by hunting and trapping. Among the Nandi the Ogiek are the hunters, but the Kunono fulfil this menial role for the Masai. The Embu speak of pre-Embu inhabitants of Kenya as "Agumba" or "Asi," pygmies, forest-dwellers and hunters. The northern Watta of Lake Tana are fishers and skilled watermen, who use papyrus rafts, and on Lake Kwanya the Kenyi, a Bantuized type of nomad, live on the papyrus marshes and are completely aquatic without any interests on the land, being reminiscent culturally of the Batwa on Lake Bangweulu.

Wherever the nomads are found in East Africa they are treated as pariahs and are engaged in trades or occupations which are considered ignoble, such as hunting, fishing, metallurgy, leather-tanning and pottery. Among the Kaffa and the Galla they provide the executioners. They are dispossessed rather than conquered, and though among the Kaffa they perform menial services like the collection of fuel it is just among the Kaffa that their tribal organization is most developed under an independent chief.

They adopt the language of the tribes among whom they live, and in many cases their social organization, costume and even religion. Thus the Sanya have a clan organization based on Galla clans with Galla clan names, and have imitated the Galla initiations and system of age-grades. The Somaliland nomads use Mohammedan invocations and celebrate the Mohammedan feasts in addition to their own pagan ritual. But, generally speaking, their religion is a vague ancestor-worship. Except when, like the southern Watta, they build temporary villages they are monogamous, and the family wanders from place to place erecting no more than a rude shelter for the night. When anything more permanent is built the little huts are situated close to river banks and are roughly thatched with palm fronds. The northern Watta have portable cane huts which they carry with them in their wanderings. Caves are also used as dwellings and others build hiding-places in trees. They possess no domesticated animals except dogs, and few practise agriculture, and that only of the most elementary kind. Their weapons are the bow and arrow with sometimes a spear in addition, and poison is applied to all weapons. The northern Watta, like the Ogiek, use a hunting spear with a detachable head, which carries the owner's distinctive mark enabling him to claim the kill. Game pits are used also.

Usually they are naked, but they may adopt some of the costume of their neighbours. Thus among the Kaffa the nomads have adopted the Kaffa headdress, a conical hat of monkey fur, and wear the large skin aprons worn by their Kaffa overlords. The Fuga, adjacent to the Watta, now clothe themselves with the typical Galla kilt. The Midgan women plait their hair after the Somali fashion, but long, plaited hair is an indigenous characteristic among several groups, particularly in the Bantu zone, as among the Amba negrillos on the Western flanks of Ruwenzori. The Ogiek plait their hair like the Nandi and wear a skull-cap made from the stomach of a goat like their Kamasia neighbours.

Everywhere the nomads, despite their low status, are respected and feared, both for their knowledge of poisons and of sorcery in which they are thought to be most proficient. This attitude points to the probability that they were the original owners of the country, their conquerors recognizing their greater spiritual affinity with the soil together with its magical implications; and tends to discredit a Watta legend (of doubtful authenticity) that the Watta

were banished from Egypt and on arrival at their present habitats were subjected by the Hamites who were already in possession of the country.

NOME, an Alaskan town on the shore of Seward peninsula, 115 m. from St. Michael; in 1900 the largest settlement in the Territory. Pop. (1900) 12,488; (1920) 852. Gulch gold was found near Nome on Anvil creek in Sept. 1898, and diggings on the ocean beach were first worked in July 1899. The rush to Nome in 1900 was one of the most remarkable stampedes in American mining history; the town soon had hotels, banks, stores, several newspapers and weekly mails from the United States; for part of the year there were, it was estimated, 20,000 inhabitants. By 1903 the population had greatly decreased, and in subsequent years the winter population averaged about 3,500, the summer population from 7,000 to 8,000. In 1905 the gold output of the Nome region amounted to about \$2,500,000, nearly all from placers, though some quartz mining was done. The output in 1926 in Nome and vicinity (Seward peninsula) was \$1,873,000. The nearest harbour is at Point Clarence, 80 m. west. At Nome, the winter ice-floes are sometimes 30 ft. high on the beach. It was first called Anvil City; the name "Nome" is derived from Cape Nome, first so called on a chart dated 1849, and said to have been a draughtsman's mistake for the query "?Name" on the original chart.

NOMENOË or **NOMNOE** (d. 851), duke of Brittany. To pacify Brittany, Louis the Debonair named him count of Vannes in 819 and governor or duke of Brittany in 826. Throughout the reign of Louis, Nomenoë maintained peace in Brittany. But in 841 he resolved to make himself independent of Charles the Bald. In 843 Charles made a vain attempt to subdue Brittany. In 844 Nomenoë invaded Maine, and in 845 the emperor was completely defeated at Ballon near Bain-de-Bretagne. In 846 Charles recognized the independence of Brittany. Having resolved to detach the duchy from the ecclesiastical province of Tours, Nomenoë accused the Frankish bishops of Vannes, Quimper, Dol and Léon of simony at the council of Coëtloh in 848, replaced them by Bretons, and erected Dol into a metropolitan see. In 849 Nomenoë attacked the Frankish county of Anjou. Charles established a garrison at Rennes. Nomenoë seized Rennes, Nantes and Upper Brittany, and ravaged Maine. In 851 he seized Anjou and invaded Beauce. He died suddenly, leaving as his successor his son Erispoë.

See A. de la Borderie, *Histoire de Bretagne*, vol. ii. (1898); R. Merlet, "Guerres d'indépendance de la Bretagne," in the *Revue de Bretagne, de Vendée et d'Anjou* (1891).

NOMINALISM, the name of one of the two main tendencies of mediaeval philosophy, the other being Realism (from Lat. *nomen*, name). The controversy between nominalists and realists arose from a passage in Boëthius' translation of Porphyry's *Introduction to the Categories of Aristotle*, which propounded the problem of genera and species, (1) as to whether they subsist in themselves or only in the mind; (2) whether, if subsistent, they are corporeal or incorporeal; and (3) whether separated from sensible things or placed in them. The Realists held that universals alone have substantial reality, existing *ante res*; the Nominalists that universals are mere names invented to express the qualities of particular things and existing *post res*; while the Conceptualists, mediating between the two extremes, held that universals are concepts which exist in our minds and express real similarities in things themselves. Though a strong realist tendency is evident in the system of Erigena (9th century), the controversy was not definitely started till the 11th century: it lasted till the middle of the 13th, when the first period of scholastic philosophy ends. Under an appearance of much vain subtlety the controversy about universals involved issues of the greatest speculative and practical importance: realism represented a spiritual, nominalism an anti-spiritual, view of the world; while realism was evidently favourable, and nominalism unfavourable, to the teaching of the Church on the dogmas of the Trinity and the Eucharist. Nominalism was a doctrine of sceptics and suspected heretics, such as

Berengar of Tours and Roscellinus. Even Abelard's mediating doctrine of conceptualism (*q.v.*) was sufficiently near to obnoxious ideas to involve him in lifelong persecution. The principles of the great orthodox philosophers of the later scholastic period which begins in the 13th century, Albertus Magnus and Thomas Aquinas, were those of moderate realism. When nominalism was revived in the 14th century by the English Franciscan, William of Occam, it gave evidence of a new tendency in thought, a distrust of abstractions and an impulse towards direct observation and inductive research, a tendency which had its fulfilment in the scientific movement of the Renaissance. Occam's dictum "*Entia non multiplicanda sunt praeter necessitatem*" was inspired by a spirit similar to that of Bacon. Though nominalism is properly a mediaeval theory, the tendency has passed over into modern philosophy: the term "nominalist" is often applied to thinkers of the empirical, sensationalist school, of whom J. S. Mill may be taken as the chief representative. (H. St.)

NOMOGRAPHY, a comparatively recent development in applied geometry, analogous to descriptive geometry or to graphical statics. Its object is the general study of the representation, by means of diagrams call *nomograms*, of mathematical laws (Gr. *nomos*, a law) which are expressed analytically by means of equations with any number of variables. The principle involved in representations of this kind was first applied, in the case of a law involving only two variables, by Descartes when, by means of co-ordinates, he showed that every equation in two variables corresponds to a plane curve.

In constructing such a graph we may neglect all measurements, simply drawing on squared paper, divided, say, into millimetres and having two graduated axes, *OX* and *OY*. A simple reading is then sufficient to give the different values of the variables as thus connected. This method of representation is now perfectly familiar even to those who are not mathematicians.

Thus, to represent the law, $f(z_1, z_2) = 0$, trace a curve whose cartesian equation is, $f(x, y) = 0$, on squared paper where $x = z_1$, and $y = z_2$. In the case of a law involving three variables, $f(z_1, z_2, z_3) = 0$, the solution that first suggests itself is to give to z_3 any arbitrary value and then to proceed as in the example above. If, however, we give to z_3 a series of sufficiently contiguous values, and for each of these construct the lines to represent the laws of z_1 and z_2 , then it suffices to write beside each line the value of z_3 which served in its construction; for then the lines $x = z_1$, and $x = z_2$, parallel to the axes of the diagram, and the line z_3 , pass through the same point if the values of z_1 , z_2 , and z_3 , satisfy the given equation. Margetts applied such an idea in his *Longitude and Horary Tables* (published in London in 1791). It was also put into systematic use by Pouchet and published in his *Arithmétique linéaire* (an appendix to his *Métrologie terrestre* [Rouen, 1797]). Since that time the idea has gained wide usage.

It should be observed that it is arbitrary to take z_1 and z_2 and that we can as well replace the axes by two simply infinite systems of lines, the one determined by the values of z_1 , and the other by the values of z_2 . At the outset, one will be tempted to see in this only a useless complication, since representation by means of rectangular axes in a plane does not lend itself to equations in three variables. However, there are many instances where, in replacing the rectangular axes by other systems of lines made to correspond to z_1 and z_2 , we obtain straight lines also for z_3 , which formerly had to be traced out point by point on the ordinary squared paper. Hence arises a greater rapidity, simplicity and precision of the new construction.

The underlying idea of such a transformation was formulated in 1842 by Lalanne, under the name, the *principle of anamorphosis*. This transformation was generalized to a high degree in 1884 by Massau. M. d'Ocagne also helped to generalize this transformation when, recognizing the ease of drawing circles, he developed a theory of representation of equations by three systems of circles (S.52 in the first edition of his *Traité de Nomographie*, 1899).

By means of concurrent lines it is impossible to represent equations of more than three variables, since it is not possible to represent on a plane any system of lines of more than two parameters. Nevertheless, it was possible to use this method for cer-

tain equations in more than three variables if, by introducing auxiliary variables, one could replace the given equation by a series of equations in three variables. A particular example of this device was proposed by Lallemand, in 1885, in the form of *binary scales* which he introduced in his *abaques hexagonaux* (an ingeniously combined variation, in view of certain practical ends, of Lalanne's *abaques* with their three pencils of parallel lines). In view of the nature of a nomographic diagram, Lalanne applied to it the name *abacus* ($\alpha\beta\alpha\xi$), and the term has remained.

But to obtain an *intrinsic* representation of an equation of more than three variables, without introducing auxiliary variables, it is necessary to make use of some other principle of representation. The first principle of this kind to appear was that of *collinear points*, which was introduced by M. d'Ocagne in 1884, and has proved to be so usable that, for equations with four variables, such as are found in practical work, it is employed almost universally. The method was derived from a particular application of Charles's principle of duality, together with a special system of tangential co-ordinates (called *parallels*); it substituted for the concurrent lines of the older anamorphotic diagrams the collinear points; and where in the older method it was only possible to represent a simply infinite system of lines, one could diagrammatize a doubly infinite system of points. This explains why, with concurrent lines, intrinsic representation was limited to three variables, and why it is now possible to include as many as six variables.

As a typical example of an equation which it was not possible to represent by means of concurrent lines, which can easily be treated by means of collinear points, there may be mentioned quadrinomial equations, or more particularly, a complete cubic equation, which we meet with in certain problems of hydraulics and resistance of materials; also the fundamental formulas of spherical trigonometry (which leads to the nomographic solution of all problems in astronomy of position and in navigation); d'Ocagne has also shown that all such problems can be resolved by means of a special unique nomogram. (*Comptes Rendus de l'Académie des Sciences*, vol. 138, p. 70, 1904; and *Bulletin de la Société Mathématique de France*, vol. 32, p. 196, 1904.)

In 1891, under the name *Nomography*, then used for the first time, M. d'Ocagne worked out a synthesis of all the methods of graphic representation proposed up to that date, taking the various points of difference and welding them into a unity of conception. Since then he has continued to search for means of extending these methods into various fields of practice.

In considering a number of planes superimposed upon each other, each with its given geometrical elements numbered or not (called *constants*), among which is established a certain graphic liaison, he has been able to extend these methods and make them as general as possible with a given number of variables. To develop this idea, let us call E_1 a geometrical element (point or line) defined by the parameter z_1 . Now, the aggregate of elements E_i , constitutes the system (E_1), and each element is determined by the corresponding value of z_1 .

If such systems as (E_1), (E_2), . . . , (E_n), fixed or subject to displacement, one with respect to another, co-exist in a plane, and if they are placed in such a way as to realize between the elements a given graphic liaison, this liaison will be expressed by an analytical relation of the corresponding values of the variables, z_1, z_2, \dots, z_n such as $f(z_1, z_2, \dots, z_n) = 0$. This aggregate of numbered systems, completed at the moment when graphic liaison is realized between them, constitutes a nomogram of the equation. Such a nomogram permits, by a simple reading (which guides the graphic liaison in question), the determination of the values of any one of the variables entering into the equation considered, when the values of the other $n-1$ are given.

After these explanations it is easy to perceive what the object is in the more general problems of nomography; one might formulate it thus: one equation being given, to construct a nomogram by means of systems (E_1), (E_2) . . . (E_n) as quickly and easily as possible (*i.e.*, by means consisting exclusively, if possible, of points, straight lines, or circles); a graphic liaison would be established at once between them.

To do this, it is necessary at the outset by a kind of inverse process, to study the types of nomograms conceived *a priori* as the most simple for obtaining the canonical forms of the corresponding equations; for recognizing the conditions necessary for an equation to be reduced to one of these forms; and when this reduction is possible, for deciding the simplest and most direct means of constructing the corresponding systems. It was the need for presenting the nature of mathematical problems that gave rise to nomography, problems into the details of which we need not enter here.

However, without entering into detail, one can take account, more or less, of the manner by which one forms rationally the fundamental types of nomograms. To do this it is first necessary to understand what, being immediately discernible, constitutes a graphic liaison. The only relation of position between two geometrical elements that one can judge at a glance with sufficient exactness is a contact and, more specifically, a contact between line and point; in this connection the parallelism of two straight lines (which one can also judge with some precision) may also be considered, for it is in effect the contact of one of the straight lines with the point at infinity of the other.

The notion of the graphic contact being thus understood, we come easily to the conviction that every graphic liaison intervening in a nomogram consists simply in the simultaneity of many contacts between numbered elements or constants. Such is the postulate that is to be found at the base of nomography. While we must occasionally consider intervening contacts, confined in practice almost always to contacts between points and lines (parallelism included), the contacts between lines are so infrequent that we may neglect them in this sketch.

It is proper to recall here, as we have noted above, that we can only consider, on a plane, those systems of lines which depend upon a single parameter; on the other hand, it is possible to consider a doubly infinite system of points which has been formed by the mutual intersections of lines taken in two simply infinite systems. The aggregate of these two systems forms what is known as a *réseau* (net). From this it follows that the maximum number of variables directly intervening in the same contact is, at most, three; two being affected by the point, the third by the line entering into the contact. But there must be three contacts, from one plane to the other, to fix the position of a moving plane in reference to a fixed plane. The position being thus fixed, it is then possible to establish a contact between elements belonging to each of the planes; we may then secure an intrinsic representation for equations having as many as 12 variables. This principle was communicated to the Académie des Sciences de Paris by M. d'Ocagne in 1893 (*Comptes Rendus*, vol. 117, p. 216 and 277). If one of four intervening contacts is reduced to a parallelism of the axes OX and $O'X'$ of the two planes, the orientation of the moving plane remains constant in relation to the fixed plane, and can be treated by a type of nomogram which permits intrinsic representation of as many as nine variables. This problem was made the subject of a profound study by Margoulis under the title *L'abaque à transparent orienté*.

If we consider a case where n moving planes are fixed simultaneously on a fixed plane, the fixation of each of them is made by three contacts, and it can be seen that we thus arrive at the most general type of nomogram permitting the intrinsic representation of equations up to $3(n+1)$ variables.

Nomography reached its full development in the comprehensive *Traité* of M. d'Ocagne, published in 1899, and crowned with the Prix Poncelet (in 1902) by the Académie des Sciences. Since the appearance of this work, later theoretical developments have been made by Soreau, Farid Boulad, Clark, Gercevanoff, Margoulis and others, and the applications have multiplied to an extraordinary degree. Among these applications, the most numerous are those derived from the principle of the collinear points, relating moreover to all kinds of technical fields. The library of the Ecole des Ponts et Chaussées in Paris has a considerable collection of material, brought together for most part by M. d'Ocagne. Next to the above method, the orientation of transparents, due to Margoulis, seems to be the most fruitful. Indeed, he has opened up a large

number of interesting applications relating to hydrodynamics, aerodynamics, aviation, etc.

NONCONFORMIST, a term denoting historically (a) those persons who at the beginning of the 17th century refused to conform to certain practices, e.g., the wearing of the surplice, kneeling at the reception of the Sacrament, etc., of the Church of England; (b) those who, after the passing of the Act of Uniformity 1662, refused to conform to that act and ceased to be members of the church. In current usage the term "nonconformist" is applied in Great Britain to any member of a church not conforming to the ceremonies, worship and doctrines ("forms") of the Church of England, but is generally used of a member of the so-called Free Churches, or Protestant Dissenters, and is not usually applied to Roman Catholics.

NONCONFORMITY, LAW RELATING TO. See ENGLISH HISTORY; BAPTISTS; CONGREGATIONALISM; METHODISM; FRIENDS, SOCIETY OF, etc.; also OATH. It is proposed here to note the matters in which the law as to nonconformists still differs from that applicable to members of the Church of England.

(1) *Judicial Notice.* Where the tenets and authorities of a nonconformist body come in question they must be proved by evidence. By Lord Lyndhurst's act, the Nonconformist Chapels Act, 1844, where no particular religious doctrine or mode of worship has been prescribed by the deed or instrument of trust the usage of the congregation for 25 years is to be taken as conclusive evidence of the doctrine and worship which may be properly observed in such meeting-houses. (2) *Tribunal.* Matters arising in nonconformist bodies can only be tried by the ordinary secular courts, and generally depend upon the question whether a minister has done any act which is not in accordance with the rules governing the particular body of which he is a minister. A nonconformist body is in law nothing more than a voluntary association, whose members may enforce discipline by any tribunal assented to by them, but must be subject in the last degree to the courts of the realm. (3) *Status of Ministers.* A nonconformist minister is not in holy orders, and his chapel is not a consecrated building. His status is, however, recognized to a limited extent. By the Toleration Act, 1 Will. and Mar., c. 18, a minister, preacher or teacher of a nonconformist congregation is exempt from certain parochial offices, as that of churchwarden. He is also exempt from serving in the reserve forces or on a jury. These privileges only attach

where the place of worship of which he is a minister has been duly registered (the Places of Worship Registration Act, 1855), unless in the case of bodies subject to special legislation as Quakers. By the Municipal Corporations Act, 1882, s. 12, a nonconformist minister (as is a clerk in holy orders) is disqualified from being elected an alderman or councillor of a town council, but under the Local Government Act, 1888, a clerk in holy orders, or other minister of religion, may be a councillor or alderman of a county council, and, under the London Government Act, 1899, of a metropolitan borough. (4) *Marriage*. The first act of parliament relieving dissenters (other than Jews and Quakers) from restrictions was the Marriage Act of 1836. By that act the ceremony of marriage might be performed in a nonconformist place of worship, but it must be after due notice to the superintendent registrar and in his presence or in that of a registrar, and the building must be one that is duly certified for marriages. The Marriage Act, 1898, dispensed with the necessity of the attendance of a registrar at marriages celebrated at a nonconformist place of worship, substituting in place thereof a person duly authorized by the trustees of the place of worship, if the persons intending to be married so desire; but the parties may, if they wish, still require the presence of the registrar. Marriage by banns, licence or special licence cannot take place except in a church. (See *MARRIAGE*.) (5) *Burial*. By the Burial Laws Amendment Act, 1880, burial may take place in a churchyard without the rites of the Church of England. But in such a case notice must be given in a specified form, which is unnecessary where the burial service is conducted by a clergyman of the Church of England. (See *BURIAL*.) (6) *Parish Offices*. By 1 Will. and Mar., c. 18, s. 5, a dissenter chosen churchwarden and scrupling to take the oaths may execute his office by deputy. His acceptance of office is made optional by the act; there is nothing to prevent his discharging it if he see fit to do so. This seems to be still the law, although a declaration was substituted for the oath by the Statutory Declarations Act, 1835, s. 9. (See *DISSENTER*; *JEWS*; *ROMAN CATHOLICS*.)

NONFEASANCE, MISFEASANCE, MALFEASANCE. The expressions "nonfeasance" and "misfeasance," and occasionally "malfeasance," are used in English law with reference to the discharge of public obligations existing by common law, custom or statute. The rule of law laid down is that no action lies for nonfeasance, *i.e.*, for failure or refusal to perform such obligation, but that an action does lie for damage resulting from misfeasance or malfeasance, *i.e.*, for negligently and improperly performing the obligation. (See *NEGLIGENCE*.) At present the terms misfeasance and nonfeasance are most often used with reference to the conduct of municipal authorities with reference to the discharge of their statutory obligations. In the case of nonfeasance there is a remedy by indictment or *mandamus* or by the particular procedure prescribed by the statutes. This rule is fully established in the case of failure to repair public highways; but in other cases the courts are astute to find evidence of carelessness in the discharge of public duties, and on that basis to award damages to individuals who have suffered thereby. Misfeasance is also a term used with reference to the conduct of directors and officers of joint-stock companies.

NONIUS MARCELLUS, Latin grammarian and lexicographer, flourished at the end of the 3rd or the beginning of the 4th century A.D. He is the author of a sort of lexicon called *De compendiosa doctrina*, in 20 sections or chapters, the first twelve of which deal with language and grammar, the remaining eight with special subjects (navigation, costume, food, arms). It is valuable as preserving fragments from old dramatists, annalists, satirists and antiquarian writers. In the quotations from the authors cited Nonius always follows the same order, beginning with Plautus and ending with Varro and Cato. In the 5th century Julius Tryphonianus Sabinus brought out a revised and annotated edition.

Editions by L. Müller (1888); J. H. Onions, bks. i.-iii. (1895); W. M. Lindsay (1903).

NONJURORS, the name given to those beneficed clergy of the Church of England who refused to take the oaths of alle-

giance to William and Mary in 1689. They were about 400 in number, and included William Sancroft, archbishop of Canterbury, and four others of the "seven bishops": Thomas Ken of Bath and Wells, John Lake of Chichester, Thomas White of Peterborough and Francis Turner of Ely, together with the bishops of Gloucester, Worcester and Norwich. Other distinguished nonjurors were: William Sherlock, master of the Temple, Jeremy Collier, the ecclesiastical historian, George Hickes, dean of Worcester, Nathanael Spinckes, John Fitzwilliam, canon of Windsor, Henry Dodwell, Camden professor of history at Oxford, Henry Hyde, second earl of Clarendon, and Roger North, the lawyer. Afterwards their number was augmented by refusals to swear the oaths of allegiance to George I. Ken, the most eminent of the nonjurors, disapproved of their subsequent proceedings, and Sherlock and Dodwell afterwards took the required oaths, the former becoming dean of St. Paul's.

Believing in the doctrine of non-resistance to established authority, the nonjurors argued that James II. was still the rightful king, and likened the position of William to that of Cromwell. With the approval of William III., Gilbert Burnet, bishop of Salisbury, attempted to reconcile them to the new order; and it was only when the generous terms offered by Burnet had been refused, that, in Feb. 1690, they were deprived of their sees and other benefices. Although they had only a small following among the mass of the people, who were not required to take the oaths of allegiance, Sancroft and his colleagues claimed to represent the true Church of England, and requested James II. in his exile to nominate two new bishops to carry on the episcopal succession. James chose Hickes and Thomas Wagstaffe (1645-1712), who were consecrated in 1694 as bishops of Thetford and Ipswich respectively. A further consecration took place in 1713 when Collier, Spinckes and Samuel Hawes (d. 1722), were consecrated "bishops at large." In 1718 the introduction of a new communion office with some "usages" taken partly from primitive liturgies, and partly from the first prayer-book of Edward VI. caused a schism among the nonjurors, dividing them into "Usagers" and "Non-Usagers." The four "usages" were: The mixed chalice, prayers for the faithful departed, prayer for the descent of the Holy Ghost on the consecrated elements, and the Oblatory Prayer, offering the elements to the Father as symbols of His Son's Body and Blood. Accepting the "usages" the two bodies united in 1731, but other dissensions followed, although the episcopal succession was maintained until the death of a bishop named Charles Booth in 1805. The last nonjuror was probably James Yeowell, who died in 1875. Public worship was conducted in chapels or "oratories," and in private houses.

In Scotland the nonjurors included the greater part of the clergy of the Episcopal Church, which ceased to be the state church in 1689. The Scottish clergy maintained their opposition to the government until the death of Prince Charles Edward Stuart in 1788, when the bishops met at Aberdeen, and unanimously agreed to submit to the government of King George III. A large number of the Presbyterians in Scotland, principally found among the Cameronians, also refused to take the oaths of allegiance to William and Mary; but as their reasons for this refusal were quite different from those of the episcopalian nonjurors, they are not usually referred to by this name (see *CAMERONIANS*).

For the history of the nonjurors, see Macaulay, *History of England* vol. ii. (1895); T. Lathbury, *History of the Nonjurors* (1845); J. H. Overton, *The Nonjurors* (1902), a defence of the sect.

NONNUS (Egyptian for "saint"), Greek epic poet, a native of Panopolis (Akhmim) in the Egyptian Thebaid, probably lived at the end of the 4th or beginning of the 5th century A.D. His principal work is the *Dionysiaca*, an epic in 48 books, the main subject of which is the expedition of Dionysus to India and his return, a subject convenient at the time owing to the popular comparison of Alexander with Dionysus. In its luxuriance and preoccupation with action, it resembles the Indian epics. His chief merit consists in the systematic perfection to which he brought the Homeric hexameter, but this very quality tends to monotony. His influence on later poetic vocabulary was considerable.

We also possess under his name a paraphrase (*μεταβολή*) of the

Gospel of St. John, which is chiefly interesting as apparently indicating that Nonnus in his later years was a convert to Christianity. His style, in this content, produces an impression of extreme bombast and want of taste. According to an epigram in the Palatine Anthology (ix. 198), Nonnus was also the author of a *Battle of the Giants*, and four lines of the *Bassarica* (also on Dionysus) have been preserved in Stephanus of Byzantium.

Editio princeps (1569); H. Köchly ("Teubner" series, with critical introduction and full index of names, 1858); the most generally useful edition is that by the comte de Marcellus (1856), with notes and prolegomena, and a French prose translation. On the metre, see J. G. Hermann, *Orphica* (1805), p. 690; A. Ludwich, *Beiträge zur Kritik des Nonnus* (1873), critical, grammatical and metrical; C. Lehrs, *Quaestiones epicae* (1837), pp. 255-302, chiefly on metrical questions; on the sources, R. Köhler, *Über die Dionysiaka des Nonnus* (1853), a short and connected analysis of the poem, with a comparison of the earlier and later myths; see also I. Negrissoli, *Studio critico . . . Nonnus Panopolita*, with short bibliography (1903). The paraphrase on St. John (editio princeps, c. 1505) is edited by F. Passow (1834) and A. Scheindler (1881), with complete index.

NONPAREIL (see PRINTING; TYPE), a size of type smaller than minion and larger than ruby. It is also known as 6-point. It is mainly used for footnotes. The following matter is printed in nonpareil:

In Europe, as late as the second half of the 17th century, every book and every public and private document was written by hand; all figures and pictures, even playing cards and images of saints, were drawn with the pen or painted with the brush.

NONPAREIL or **PAINTED BUNTING**, a small, brilliantly coloured finch (*Passerina ciris*) with blue head, green-yellow back, scarlet body and black wings and tail. After wintering in Central America, the painted bunting arrives in the southern states of the U.S.A. in April, and breeds north to Virginia, Ohio and Kansas. The "pin-tailed nonpareil" of Africa (*Erythrura prasina*) is blue in colour; the male has a long tail. It belongs to the *Ploceidae*. (See WEAVER-BIRD.)

NONPARTISAN LEAGUE, an American political and economic organization of farmers founded by Arthur C. Townley at Bismarck, N.D., in Feb. 1915. For years the farmers of the State had complained of exploitation by grain speculators, bankers and politicians. The 1915 session of the legislature, at which members of the Equity Society—a farm organization—received scant attention, fanned agrarian discontent into immediate flame. The Nonpartisan League, applying modern sales methods, rapidly organized the farmers into a cohesive political body, which captured control of the State Republican Party and elected its candidates for State offices and Congress. In 1916 the league began work outside North Dakota, and eventually established active organizations in 12 other Western and Middle Western States, where influence was exerted in behalf of sympathetic candidates with varying degrees of success. Though confining its own membership to farmers, the league regularly co-operated with urban labour in political action. During the World War the league was bitterly attacked on the ground of the socialist connection of some of its leaders and its advocacy of conscription of wealth to pay for the hostilities. In 1919 the league put its economic programme into effect in North Dakota. A State-owned bank, mill and terminal elevator, home-building association, and hail, fire and tornado insurance constituted the principal enterprises. All of these, except the home-building association, were still in operation in 1928. The league, as such, gradually disintegrated, though not before it had given birth to the Farmer-Labor Party in Minnesota and had stimulated many farmers to "non-partisan" voting.

BIBLIOGRAPHY.—Because of the bitter controversy over the league, little unbiased discussion exists. See H. E. Gaston, *The Nonpartisan League* (1920), and C. E. Russell, *Story of the Nonpartisan League* (1920) both sympathetic, while A. A. Bruce, *The Nonpartisan League* (1921) is hostile. The files of the *Nonpartisan Leader* (later the *National Leader*), which was published up to July 1923, give a running account of the league's work. (N. A. C.)

NON-SHATTERABLE GLASS: see GLASS, SAFETY.

NONSUIT, in law, the name given to a judgment whereby an issue is determined against the plaintiff. It was a term peculiar to the English common-law courts before the Judicature Acts, and was simply the expression of the opinion of the court that, apart from the merits, the plaintiff's case was incomplete. It did not in

any way act as a bar to his bringing another action for the same cause. Although judgment of nonsuit still exists, it has, since the Judicature Acts, the same effect as a judgment on the merits, unless the court otherwise directs.

In the United States, litigants often take a "nonsuit" when a case has been settled out of court or they realize the futility of further proceedings.

NORD, the most northern department of France. Area 2,228 sq. miles. Pop. (1926) 1,969,159. Bounded for 21 m. by the North sea, it has Belgian territory on the north-east and east. It lies below, and parallel to, the chalk scarp of Artois, famous for its defence in the War of 1914-18. The coast is formed largely of sand-dunes drained by canals. The department is crossed by the Scheldt (Escaut) with its tributaries and by the Sambre, the chief tributary of the Meuse. The climate of Nord is colder than that of France in general, the mean temperature being 49° or 50° F. The average annual rainfall is about 28 inches.

In agricultural and industrial importance Nord is the first of French departments. In the south-east stock-raising flourishes; in the central zone beetroot is characteristic, while mixed farming prevails in the north-west. Cereals (especially wheat and oats) and potatoes are grown in abundance, while flax, tobacco, chicory, colza and hops are minor crops. Market-gardening and horticulture are practised in some localities. There are mineral springs, notably at St. Amand, where the mud baths are used in the treatment of rheumatism. The mineral wealth lies chiefly in coal mines forming part of the Valenciennes basin, the most important in France, which extends into Belgium and Pas-de-Calais. The textile industry centres in Lille, Roubaix and Tourcoing, which spin and weave cotton, linen and wool, as also around Fourmies. Other centres are Armentières (cloth-weaving), Dunkirk (flax, jute and hemp-spinning), Cambrai (batiste and other delicate fabrics; also chicory), Douai, Avénes, le Cateau and Caudry. Other great industries are glass, brick, pottery and sugar manufacture, alcohol-distilling, dyeing, iron-founding and steel production. Branches of the metallurgical industry are at Denain, Hautmont, Maubeuge, Valenciennes, Douai, Raismes, etc. Dunkirk and Gravelines equip fleets for the cod and herring fisheries. Dunkirk is the chief port. Its system of inland navigation is highly developed, comprising a line of waterways from the Scheldt to the North sea at Dunkirk, with which the coal basin of Valenciennes is linked by the canalized Scheldt and the textile region of Lille by means of the Deûle canal and the canalized Lys.

The department is divided into six arrondissements (Avesnes, Cambrai, Douai, Dunkirk, Lille, Valenciennes) with 68 cantons and 668 communes. It forms the archiepiscopal diocese of Cambrai and part of the region of the I. army corps (headquarters at Lille) and of the educational division of Lille. Its court of appeal is at Douai.

NORDAU (originally **SÜDFELD**), **MAX SIMON** (1848-1923), Jewish-Hungarian author, was born at Budapest on July 29, 1849, and practised medicine in his native town. He made his name by his pseudo-philosophical *Entartung* (Eng. trs. *Degeneration*, 1895), which was translated into many languages, and had a great vogue. Other works were *The Conventional Lies of Society* (Eng. version 1895), and *Biologie der Ethik* (1921). Nordau was an ardent Zionist, and took Herzl's side in wishing to accept the British Government's offer of land for a Jewish settlement in East Africa. In 1903 an attempt was made on his life by a Jew opposed to the scheme. He died on Jan. 22, 1923.

His works include novels and stories: *Gefühlskomödie* (1892); *Die Drohnenschlacht* (1897), *Morganatisch* (1904), etc.; dramas: *Das Recht zu lieben* (2nd ed. 1894), *Doktor Kohn* (1898), and others; some books of travel; and the critical works *Zeitgenössische Franzosen* (1901), and *Von Kunst und Künstlern* (Leipzig, 1905).

NORD DE FRANCE, COMPAGNIE DES CHEMINS DE FER DU. This company was one of the earliest formed for general transport in France. It was founded on Sept. 18, 1845, and in the following year its rolling stock totalled 175 locomotives, 420 trains and 1,600 trucks. The mileage in that year was 355 km., necessarily confined to a very limited area. Year by year the company made new departures and put out new branches exploiting new territories, and in 1928 the rolling stock

had increased to 2,857 locomotives, 7,322 trains, and 88,742 trucks. The length of lines operated had increased tenfold to 3,830 kilometres. The company's activities were somewhat limited by the area it professed to serve, and the formation of other railway companies, whose tracks hedged in the field already occupied by the Compagnie du Nord.

The company serves the industrial area north of Paris to the English Channel, and is the main artery system of communication from the big manufacturing plants to Paris. It is, from its closeness to England, much concerned with the cross-Channel ferry steamers, making connections with express train and boat services for visitors to Paris. Express passenger and freight services are constantly maintained, and the company arranges special programmes of trains for the holiday season, to connect at Paris with the trains of other lines for Switzerland, Italy, etc. The total invested capital of the company had reached (in Dec. 1927) the sum of 6,642,499,000 francs. (GIR.)

NORDDEUTSCHER LLOYD STEAMSHIP COMPANY. The Norddeutscher Lloyd was founded on Feb. 20, 1857, by Consul Hermann Heinrich Meier. The first steamer line was between Bremen and England. On June 19, 1858, Lloyd's first ocean steamer, the "Bremen," commenced the first trip to New York. The following years were chiefly devoted to building up traffic from Bremen to North America; in 1868 the boats of the Norddeutscher Lloyd already served all the large ports of the east coast of North America; in 1870 the West Indian and Baltimore lines were called into existence. Under the management of Lohmann, the company advanced in the year 1890 to the position of the fourth largest shipping company in the world. In the year 1881 the company, following English examples, introduced the first fast steamer in the New York line. The year 1886 brought about the opening of the Government mail steamer line to East Asia and Australia. The credit for having made the company the leading passenger shipping company of the pre-war period is due to Heinrich Wiegand, who took over the management of the company on Lohmann's death. Under Wiegand the twin-screw system was introduced and the existing line further extended. The fast steamers of the Kaiser class were by the turn of the century the most perfect which had been employed up to then in the territory of ship construction. The Lloyd fleet attained in hold-capacity shortly before the outbreak of the World War nearly 1,000,000 Gr.R.T.

The Peace Treaty then destroyed with one blow the results of 60 years' efforts. Of the fleet existing in 1914, 135 sea steamers, 358 lighters, river barges and other auxiliary vessels, of altogether 982,951 Gr.R.T. there remained to the company only their sea-side steamers, small coast vessels, lighters and tugs. The steamer "Grüssgott" (781 Gr.R.T.) was then the company's largest steamer. Added to the ship losses were the losses to buildings, docks and firm inventory abroad. In America there were lost in particular the very valuable dock installations in Hoboken.

In the meantime the company has succeeded by extensive reconstruction activity, the purchase and re-purchase of foreign tonnage and the admission of the fleets of the Roland-Line, Hamburg-Bremen Afrika-Line and the Dampschiffahrtsgesellschaft Horn, in once more bringing their tonnage up to 93% of the pre-war position and again displaying their house-flag on all seas. Among the vessels of the new Lloyd fleet, which numbered on January 1, 1929, about 928,109 Gr.R.T. (including the two four-screw turbine fast steamers "Bremen" and "Europa" also a number of re-constructed freight steamers), the s.s. "Columbus" (32,400 Gr.R.T.) working between Bremen and New York occupies a special position in her capacity as the present largest vessel of the German trading fleet. For the purpose of building up this important service the reconstructed "Bremen" and "Europa" will also find application in this direction after their completion.

The share capital of the Norddeutscher Lloyd amounted in 1928 to 160,000,000 marks ordinary capital and 5,000,000 marks preference shares. (EH.)

NORDENSKIÖLD, NILS ADOLF ERIK, BARON (1832-1901), geographer and Arctic explorer, was born at Helsingfors, on Nov. 18, 1832. He was the son of Nils Gustav Nordenskiöld,

a mineralogist and a traveller. Compelled to leave Russia for political reasons, he settled at Stockholm. He received an offer from Otto Torell, the geologist, to accompany him on an expedition to Spitsbergen. To the observations of Torell on glacial phenomena Nordenskiöld added the discovery at Bell Sound of remains of Tertiary plants, and on his return became professor and curator of the mineralogical department of the Swedish State Museum. In 1861 he took part in Torell's second Spitsbergen expedition. Of the further expedition to the same quarter promoted by the Swedish academy of science in 1864, Nordenskiöld was the leader. Three years later he headed an expedition in the iron steamer "Sofia," and reached the highest northern latitude (81° 42') then attained in the eastern hemisphere. In 1870, with three young naturalists, he visited the vast inland ice-sheet of Greenland. On his next expedition in 1872 the tenders were caught in the ice, and the crews of the three vessels were forced to winter in Spitsbergen. In 1875-1876, however, a successful voyage eastwards, including the ascent of the Yenisei, led him to attempt the discovery of the long-sought North-East Passage. Starting from Karlskrona on June 22, 1878, in the "Vega," he doubled Cape Chelyuskin in the following August, and after being frozen in at the end of September near Bering Strait, completed the voyage successfully in the following summer.

On his return to Sweden he received an enthusiastic welcome, and in April 1880 was made a baron and a commander of the Order of the Nordstjärna. In 1883 he again visited the east coast of Greenland, and succeeded in forcing through the great ice barrier, a feat attempted in vain during more than three centuries. He died at Stockholm on Aug. 12, 1901.

Baron Nordenskiöld also published *Facsimile Atlas* (1889) and *Periplus* (1897). The former contains reproductions of geographical documents printed during the 15th and 16th centuries, and the latter, a work of far greater research, deals with the history of early cartography and the sailing charts in use among mariners during the middle ages.

NORDENSKJÖLD, OTTO (1869-1928), Swedish explorer, was born in 1869; his father was a brother of Baron A. E. Nordenskiöld (q.v.). He specialized in geology in the University of Uppsala and after travels in Tierra del Fuego and Alaska, he led an expedition (Oct. 1901) to the South Polar regions. He landed at Snow Hill island, off the east coast of Graham Land. Weather conditions made it impossible for the "Antarctic," which had continued her course to Tierra del Fuego, to relieve them in 1902-03, and she sank in the attempt. After several attempts at rescue had been made, they were eventually brought back by a vessel sent by the Argentine Government in Nov. 1903. ("Antarctic" *Trä är bland sydpolens isar*, 2 vols. Stockholm, 1904; Eng. trs. *Antarctica*, 1905). In 1920-21 Professor Nordenskiöld explored the Peruvian and Chilean Andes. He died on June 3, 1928.

NORDERNEY (i.e., "northern island"), the largest of the East Friesland group, belongs to Hanover. Pop. (1925) 5,406. It is 8 m. long and about 1½ m. broad and is reached by steamer from Norddeich, Bremerhaven or Hamburg, and at low tide by road. The village is a popular resort. Norderney is associated with Heinrich Heine's *Nordseebilder*.

NORDHAUSEN, a town in the province of Prussian Saxony. It is situated on the Zorge to the south of the Harz mountains, at the west end of the Goldene Aue (Golden Plain), a fruitful valley watered by the Helme. Pop. (1925) 34,987. Nordhausen possessed a royal palace in 874 and a convent was founded here in 962. It was destroyed by Henry the Lion in 1180, but was soon rebuilt and was made a free imperial town in 1253. In this and the following century several diets and other assemblies were held here. The protector (*Vogt*) of the town was the elector of Saxony and from 1702 to 1715 the elector of Brandenburg. Nordhausen accepted the reformed doctrines in 1522. It was annexed by Prussia in 1803 and again in 1815, having in the meantime belonged to the kingdom of Westphalia. The upper and lower parts of the town are connected by flights of steps. Among its churches the most noteworthy are the Roman Catholic cathedral, late Gothic with a Romanesque crypt, and the Protestant church of St. Blasius. Near the mediaeval town hall stands a Roland's

column, the ancient symbol of free commercial intercourse and civic liberty. The chief importance of the place arises from its distilling of "Korn Schnapps," a spirit somewhat akin to whisky.

NORDICA, LILLIAN (1859-1914). American operatic soprano, was born at Farmington (Me.), May 12, 1859, trained at Boston, and later at Milan, under Sangiovanni. She made her début at Brescia in 1879, sang at Covent Garden, London (1887-93), and at the Metropolitan Opera House, New York, after 1895. She died at Batavia, Java, May 10, 1914.

NÖRDLINGEN, a town of Germany, in the republic of Bavaria, on the Eger. Pop. (1925) 8,589. From 898, when first mentioned, to 1215 Nördlingen was subject to the bishops of Regensburg, but about 1215 it became a free city of the Empire. It was annexed to Bavaria in 1803. It is still surrounded with walls and towers. The church of St. George is a Gothic structure erected in the 15th century and restored in 1880. The Late Gothic town hall has a collection of pictures and antiquities.

Military Operations.—Nördlingen was the scene of two great battles in the Thirty Years' War (*q.v.*). In the first, which was fought on Sept. 5 and 6, 1634, the hitherto invincible Swedish army, commanded by Duke Bernhard of Saxe Weimar and Marshal Horn, was defeated with great loss by a somewhat superior army of Imperialists and Spaniards under Gen. Gallas, Horn being taken prisoner. In the second battle, fought 11 years later (Aug. 3, 1645), Condé (then duke of Enghien) and Turenne were the leaders on the one side, and Mercy and Johann von Weert, the dashing cavalry commander whose onset had decided the battle of 1634, on the other. The Germans were posted some 5m. to the east of Nördlingen, about Allerheim. In rear of the village the plain was occupied by Mercy's army in the customary two lines, foot in the centre, horse in the wings. The French army, similarly arrayed, was more heterogeneous than the German. After a cannonade in which it suffered more severely than its entrenched enemy, the French centre furiously attacked the village of Allerheim; the fighting here was very heavy, and on the whole in favour of the Germans, although Mercy was killed. The right wing of the French cavalry was swept off the field by Johann von Weert's charge, but the German troopers, intoxicated with success, dispersed to plunder. On the French left, meanwhile, Turenne saved the day. Fighting cautiously at first with his leading line to gain time for his second to come up, he then charged and broke up the hostile right wing of cavalry, while some battalions of infantry scaled the hill and captured the Bavarian guns. Unlike Weert the marshal kept his troops in hand, and swung round upon the Bavarian infantry behind Allerheim, who were at the same time cannonaded by their lost guns. A prolonged fight now ensued, in which the Bavarians had the worst of it, and Weert, returning at last to the field, dared not attempt to engage afresh. The armies faced one another all night with their sentries 50 paces apart, but in the morning the Bavarians were found to have retreated. Nothing was gained by the victors but the trophies and the field of battle, and the losses of both sides had been enormous. Nördlingen, therefore, is a classical instance of the unprofitable and costly *bataille rangée* of the 17th century.

See Beyschlag, *Geschichte der Stadt Nördlingen* (Nördlingen, 1851), and Mayer, *Die Stadt Nördlingen, ihr Leben und ihre Kunst im Lichte der Vorzeit* (Nördlingen, 1856).

NORE, THE, sandbank at the mouth of the river Thames, England, marked by buoys and a lightship, with revolving light. This ship lies 3 m. from the Kent coast, about the same from the Essex coast, and 47½ m. below London Bridge. The first light was placed as an experiment by Mr. Hamblin, its patentee, in 1731.

NORFOLK, EARLS AND DUKES OF. The 1st earl of Norfolk was RALPH DE GUADER, a follower of William the Conqueror, who forfeited the earldom when he revolted against William in 1075; the 2nd was HUGH BICOP (d. 1177), one of Stephen's supporters, to whom the earldom was granted by this king before 1141. Hugh's grandson, HUGH (d. 1225), the 3rd earl of this line, married Matilda, daughter of William Marshal, earl of Pembroke, and from the Marshals their son ROGER (d. 1270), the 4th earl, inherited the office of marshal of England. This powerful family of Bigod retained the earldom until ROGER,

the 5th earl, died childless in Dec. 1306.

The next earl of Norfolk was THOMAS OF BROTHERTON (1300-1338), a younger son of Edward I., to whom the earldom was granted in 1312 by his half-brother, Edward II. In addition to the estates which had formerly belonged to the Bigods Thomas received the office of marshal. He joined Queen Isabella when she landed in England in 1326, and was one of the group of nobles who brought about the deposition of Edward II. He died in August 1338, leaving no son. The survivor of his two daughters, Margaret (c. 1320-1400), who was countess of Norfolk in her own right, married John de Segrave, 3rd Lord Segrave (d. 1353), and their only child Elizabeth (d. c. 1375) became the wife of John de Mowbray, 4th Lord Mowbray (d. 1368), and the mother of two sons John and Thomas. In 1397 the countess Margaret was created duchess of Norfolk, and at the same time her grandson Thomas Mowbray was made duke of Norfolk.

On the death of John Mowbray, 4th duke of this creation, in 1476 the dukedom became extinct, but the earldom passed to his daughter Anne, wife of the young Richard, duke of York, who was murdered in the Tower with whom the earldom became extinct.

The dukedom was given in 1483 to John Howard whose mother, Margaret Mowbray, was a daughter of Thomas Mowbray the 1st duke. The dukedom has remained in the Howard line until the present day. (See HOWARD.)

NORFOLK, HENRY FITZALAN HOWARD, 15TH DUKE OF (1847-1917), was born in London on Dec. 27, 1847, and succeeded his father, the 14th duke, in 1860. He was educated at the Oratory School, Edgbaston, and then spent some time with his uncle, Lord Lyons, in Constantinople. The duke was post-master-general from 1895 to 1900, first Lord Mayor of Sheffield in 1895, and served in the yeomanry in the South African War. His position as head of the English Roman Catholics and as premier duke and Earl Marshal made him for many years conspicuous in public life. He was throughout his life in close connection with the Vatican, and was sent by Queen Victoria in 1887 on a special mission to Leo XIII. He did not always agree with the policy of the Irish Catholic hierarchy, but he did much for Catholic education in Ireland. He was keenly interested in education generally; was one of the founders of Sheffield University, and its first vice-chancellor. The duke was concerned in the building of many Catholic churches in England, notably the church of St. John the Baptist at Norwich. He died in London on Feb. 11, 1917.

NORFOLK, JOHN HOWARD, 1ST DUKE OF (of the Howard line) (c. 1430-1485), was the son of Sir Robert Howard by his wife Margaret, daughter of Thomas Mowbray, the first duke of that family. In 1455 John Howard was sent to parliament as member for Norfolk, although he "hadde no lyvelode in the shire"; in 1461 he was knighted; and in 1470, although he appears to have been a consistent Yorkist, he was created a baron by Henry VI. He was treasurer of the royal household from 1467 to 1474, and went to France with Edward IV. in 1475. After Edward's death, however, he supported Richard III., who created him duke of Norfolk and made him earl marshal of England in June 1483. He was killed at Bosworth whilst fighting for this king on Aug. 22, 1485, and the title thus suffered attainder.

NORFOLK, THOMAS HOWARD, 2ND DUKE OF (1443-1524), son of the preceding, shared his father's fortunes; he fought at Barnet for Edward IV. and was made steward of the royal household and created earl of Surrey in 1483. Taken prisoner at Bosworth he was attainted and remained in captivity until January 1489, when he was released and restored to his earldom but not to the dukedom of Norfolk. He was then entrusted with the maintenance of order in Yorkshire and with the defence of the Scottish borders; he was made lord treasurer and a privy councillor in 1501, and he helped to arrange the marriage between Margaret, the daughter of Henry VII., and James IV. of Scotland. Henry VIII., too, employed him on public business, but the earl grew jealous of Wolsey, and for a short time he absented himself from court. He commanded the army which defeated the Scots at Flodden in September 1513, and was created duke of Norfolk in February of the following year, with precedence as

of the creation of 1483. In his later years Norfolk worked more harmoniously with Wolsey. He was guardian of England during Henry's absence in France in 1520, and he acted as lord high steward at the trial of his friend Edward Stafford, duke of Buckingham, in 1521. Among his sons were William, 1st Lord Howard of Effingham (1510?-1573), and Sir Edward Howard (c. 1477-1513), lord high admiral, who defeated the French fleet off Brest in August 1512, and died during an engagement in April 1513.

NORFOLK, THOMAS HOWARD, 3RD DUKE OF (1473-1554), eldest son of the 2nd duke, married in 1495 Anne (1475-1512), daughter of Edward IV., thus becoming a brother-in-law of Henry VII., who had married Anne's sister Elizabeth. He became lord high admiral in 1513, and led the van of the English army at Flodden in September, being created earl of Surrey in February 1514. In 1513 he took for his second wife Elizabeth (d. 1558), daughter of Edward Stafford, duke of Buckingham. In 1520 Surrey went to Ireland as lord-deputy, but soon vacated this post to command the troops which sacked Morlaix and ravaged the neighbourhood of Boulogne in 1522; afterwards he raided and devastated the south of Scotland. He succeeded his father in May 1524, and as the most powerful nobleman in England he headed the party hostile to Cardinal Wolsey. He favoured the divorce of Henry VIII. from Catherine of Aragon, and the king's marriage with his niece Anne Boleyn. In 1529 he became president of the council, but in a few years his position was shaken by the fate of Anne Boleyn, at whose trial and execution he presided as lord high steward. But his military abilities rendered him almost indispensable to the king, and in 1536, just after the rising known as the Pilgrimage of Grace had broken out, he was despatched into the north of England; he temporized with the rebels until the danger was past, and then, as the first president of the council of the north, punished them with great severity. Sharing in the general hatred against Thomas Cromwell, Norfolk arrested the minister in June 1540. He led the English army into Scotland in 1542 and into France in 1544; but the execution of Catherine Howard, another of his nieces who had become the wife of the king, had weakened his position.

His son Henry Howard, earl of Surrey (*q.v.*), was arrested on a charge of treason; Norfolk himself suffered the same fate as accessory to the crime. In January 1547 Surrey was executed; his father was condemned to death by a bill of attainder, but owing to the death of the king the sentence was not carried out. Norfolk remained in prison throughout the reign of Edward VI., but in August 1553 he was released and restored to his dukedom. Again taking command of the English army he was sent to suppress the rebellion which had broken out under Sir Thomas Wyatt, but his men fled before the enemy. He acted as lord high steward at the trial of John Dudley, duke of Northumberland; and he died on Aug. 25, 1554. Norfolk was a brutal and licentious man, but was a supporter of the Roman church, being, as he himself admits, "quick against the sacramentaries."

NORFOLK, THOMAS HOWARD, 4TH DUKE OF (1536-1572), son of Henry Howard, earl of Surrey, was born on March 10, 1536. His tutor was John Foxe, the martyrologist. Norfolk, who had already been married three times, was regarded as a suitable husband for Mary queen of Scots, who had just taken refuge in England. He presided over the commission appointed by Elizabeth to inquire into the relations between the Scottish queen and her subjects; and although he appears to have believed in Mary's guilt he was anxious to marry her. Among the Scots Maitland of Lethington favoured the proposed union; Mary herself consented to it; but Norfolk was unwilling to take up arms, and while he delayed, Elizabeth ordered his arrest and he was taken to prison in October 1569. In August 1570, after the suppression of the rising in the north of England, the duke was released; but he entered into communication with Philip II. of Spain regarding the proposed invasion of England by the Spaniards. After some hesitation Norfolk placed himself at the head of the conspirators; and in return for his services he asked the king of Spain "to approve of my own marriage with the Queen of Scots." But the plot failed; Norfolk's treachery was revealed to Lord Burghley, and in September 1571 he was arrested.

He was beheaded on June 2, 1572. He always regarded himself as a Protestant. Norfolk's first wife, Mary (1540-1557), daughter and heiress of Henry Fitzalan, 12th earl of Arundel, bore him a son, Philip, who in consequence of his father's attainder was not allowed to succeed to the dukedom of Norfolk, but became 13th earl of Arundel in succession to his maternal grandfather in 1580. Norfolk left two other sons, Thomas Howard, created earl of Suffolk in 1603, and Lord William Howard (*q.v.*).

NORFOLK, THOMAS MOWBRAY, 1ST DUKE OF (c. 1366-1399), son of John de Mowbray, 4th Lord Mowbray, was created marshal of England for life in 1385. He was then Lord Mowbray and earl of Nottingham. In 1387 Nottingham began to act with Thomas of Woodstock, duke of Gloucester, his own brother-in-law, Richard Fitzalan, earl of Arundel, and the party of nobles who wished to deprive the king of his power. They routed the royal favourite Robert de Vere, earl of Oxford, at Radcot Bridge, and Richard was at their mercy. Owing partly to Nottingham's moderate counsels the suggestion to depose him was not carried out, but in the "merciless parliament" of 1388 his favourites were "appealed" of treason and were sentenced to death. For nearly two years the chief power was in the hands of the lords appellants, as Nottingham and his friends were called, but in 1389 the king regained his authority. He detached Nottingham from his colleagues and made him warden of the Scottish marches; later he became captain of Calais and the royal lieutenant in the north-east of France. Richard took him to Ireland in 1394 and soon afterwards sent him to arrange a peace with France and his marriage with Isabella, daughter of King Charles VI. But the earl's supreme service to the king was in 1397 when Richard took a tardy but severe vengeance upon three of the appellants. In their turn these lords were "appealed" of treason before the parliament, and as on the former occasion Nottingham was one of the accusers. He was present when Gloucester was arrested at Pleshey, and Froissart says that he actually beheaded Arundel himself. Gloucester was entrusted to his keeping at Calais, and in September 1397 he reported that his prisoner was dead. The duke had been murdered, and Nottingham was probably responsible, although the evidence against him is not conclusive. As a reward he received most of Arundel's lands in Surrey and Sussex, and was created duke of Norfolk. He now began to fear for his own safety, and took the duke of Hereford, afterwards King Henry IV., into his confidence. Hereford carried his words to the king, who summoned him to his presence, and at Oswestry Norfolk accused Hereford of speaking falsely. A court of chivalry decided that the dispute should be referred to the arbitrament of single combat at Coventry; but when everything was ready (Sept. 16, 1398) for the fight Richard interposed and ordered both combatants into banishment. Norfolk was deprived of his offices, but not of his titles; he left England for Dordrecht, and after passing some months in wanderings he reached Venice, where he died on Sept. 22 or 27, 1399. The concluding scene of the duke's life in England forms the staple material of act i. of Shakespeare's *Richard II.*

NORFOLK, an eastern county of England, bounded north and east by the North sea, south-east and south by Suffolk and west by Cambridgeshire and Lincolnshire. The area is 2,044.4 sq.m., the county being the fourth in size in England.

Physical Features.—The county as a whole is low-lying, no point reaching up over 350 feet. In the extreme west we have the flat fens composed of recent alluvium, which is crossed by various dykes and ditches which help to drain the district; windmills used for this purpose are a conspicuous feature, though they are being replaced by pumping engines. To the east of the Ouse the land rises somewhat, where we have the north easterly extension of the chalk hills of England. These form the oldest rocks in the county, except for a few small patches of Kimeridge clay lying along their western side. The cretaceous rocks dip eastward under various glacial deposits such as boulder clay and gravel. The indeterminate nature of the drainage is due to glacial action. The heights also die away southward and eastward, and here the land is generally fertile and well wooded, with occasional expanses of heath. The rivers follow rather irregular courses, what

watershed there is lying across the centre of the county from south-east to north-west; the Cromer Morainic ridge forms a secondary parting at right-angles to the first. The largest rivers in the east of the county are the Yare and its tributaries the Bure and the Waveney, which forms a large part of the boundary with Suffolk. In the river valleys are large stretches of alluvial deposits.

Nearly two-thirds of the boundary of the county is formed by tidal water, but there are few bays or inlets. For the most part the coast-line is flat and low, and has been greatly encroached on by the sea, several villages having been engulfed since the Conquest. At certain points, however, blown sand is filling up some arms of the sea. From the mouth of the Yare to Happisburgh the shore is skirted by sandbanks. Thence for 20 m. it is formed of cliffs consisting of clay and masses of embedded rocks. These cliffs are succeeded by a low shingly or sandy coast stretching as far as St. Edmund's point. The shores of the Wash are formed of mudbanks, which are left dry at low water. At various points off the coast there are submarine forests, especially in Brancaster bay and in the neighbourhood of Cromer and Happisburgh.

Archaeology and History.—Palaeolithic implements have been found in the county in the valley of the Little Ouse and near Cromer. The county, because of the low rainfall and fairly strong winds, was never very heavily forested, and as such it offered a suitable home for Neolithic man, who has left extensive traces of his occupation on the chalk of the west and along the gravels in the east. A few miles north-east of Brandon there are extensive pits in the chalk dug by early man when quarrying for flint (Grimes' Graves), and in them were found numerous deer antlers used by him as picks. Bronze weapons are fairly numerous, and their distribution tallies generally with those of Neolithic artefacts. Evidence of probable contacts across the North sea is borne out by the fact that 11 beakers have been discovered in the county. Finds of the early Iron age are not numerous, but towards the end of the pre-Christian era and for some time after, Norfolk was part of the lands of the Iceni. This tribe accepted the suzerainty of the Romans at the Conquest, but at the death of their ruler, Prasutagus, and following the injustice of the Romans to his wife, Boudicca (Boadicea), and his daughters, they rebelled. Successful at first, they were finally completely defeated, and their territories ravaged by the victors. Of Roman remains in the county we have the settlement of Caister-by-Norwich, perhaps a small village at Caister-by-Yarmouth and a fort at Brancaster which guarded the Wash and the north coast, and which was the headquarters of the Count of the Saxon shore. A Roman road, known as the Péddar way, probably following a more ancient track, crosses the Little Ouse a few miles east of Thetford, and runs north-north-west across the country to near Hunstanton; another road from Colchester to Caister-by-Norwich enters the county by Scole. The eastward continuation of the pre-Roman Icknield way also crossed the county.

The district was invaded in the second half of the 5th century by Angle tribes from north Germany, who, having secured the coast districts, worked their way inland along the river valleys. East Anglia owned successively the supremacy of Kent, of Mercia and Northumbria, until in 827 the whole land was united under the rule of Egbert. In 867 the Danes under Ingvar and Ubba defeated and killed King Edmund at Thetford, and Norfolk formed an integral part of the Danelaw. In the renewed Danish attacks of the 11th century Norwich and Thetford were destroyed. At the time of the Norman invasion Norfolk formed part of Harold's earldom. Norfolk formed part of the diocese of East Anglia from its foundation in 630, and in 1075 the bishop's see was placed at Thetford, whence it was transferred to Norwich in 1093. (*See NORWICH.*)

Architecture.—With a few exceptions, the majority of the churches are Decorated or Perpendicular, or a mixture of both styles. The churches of the marshes in the north-west are noteworthy, especially those of Tilney All Saints and Walpole St. Peter's, the finest Perpendicular edifice in Britain; the rich Norman church of Castle Rising should also be mentioned. At Northwold remains one of the rare Easter sepulchres. Apart from the churches in the towns, those of Worstead, Hingham, Cawston and

Terrington St. Clement may be quoted as typical examples of the numerous fine later Gothic churches. Norfolk possessed an unusually large number of monastic foundations, but of these the remains are few and comparatively unimportant. The cathedral church of Norwich was originally connected with a very richly endowed Benedictine monastery. A foundation of almost equal importance was that of Augustinian canons at Walsingham, where there are remains of an Early English and Decorated church, a Decorated refectory and a Perpendicular gateway. The shrine of Our Lady of Walsingham was the resort of great numbers of pilgrims. Other monastic remains are Bromholm priory near North Walsham; slight Early English fragments of Beeston Augustinian priory, west of Cromer; good Norman and later remains at Binham (Benedictine) north-east of Walsingham; the Benedictine nunnery of Carrow near Norwich; the fine church (Norman and later) of the Benedictine priory at Wymondham; and the remains at Castle Acre and Thetford.

The shire-system was not definitely established in East Anglia before the Conquest, but the Domesday boundaries of Norfolk were practically those of the present day. The 36 Domesday hundreds were subdivided into leets, of which no trace remains, and the boroughs of Norwich and Thetford ranked as separate hundreds, while Yarmouth was the chief town of three hundreds. Norfolk and Suffolk were united under one sheriff until the reign of Elizabeth, the shire court for the former being held at Norwich.

In the war between John and his barons Roger Bigod garrisoned Norwich castle against the king. In the rising of 1381 Norwich was plundered by the insurgents, and in the rising of 1549 against enclosures Norwich was again captured by the rebels under Ket. In the Civil War of the 17th century Norfolk as a whole adhered to the parliamentary cause, forming one of the six counties of the Eastern Association. Lynn, however, was held for the king, and Norwich was one of the first cities to welcome back Charles II.

There are several old mansions of interest, such as the Jacobean brick building of Blickling hall, Barningham hall (1612), Hunstanton, the moated Oxburgh hall, and Cressingham manor, both of the 15th century. The larger mansions, however, such as Sandringham, are of modern date. Paston and Oxnead were successively the seats of the Paston family whose Letters are famous.

Politics and Agriculture.—Norfolk returned members to parliament in 1290, and in 1298 the county and the boroughs of Lynn, Norwich and Yarmouth returned each two members. Thetford acquired representation in 1529, and Castle Rising in 1558. Under the Reform Act of 1832 the county returned four members in two divisions, and Castle Rising was disfranchised. Under the act of 1868 the county returned six members in three divisions, and Thetford and Yarmouth were disfranchised.

At the time of the Domesday survey sheep-farming flourished almost throughout Norfolk, a flock of 1,300 being mentioned at Walton, and horses were extensively bred; numerous beehives, nearly 600 water-mills and valuable river fisheries are mentioned; and salt was made in the hundreds of Freebridge and East Flegg. There was also, after the Conquest, a well developed trade with Flanders in wool. The worsted trade was introduced by Flemish immigrants as early as the 12th century, and the woollen trade became especially prosperous in the hundreds adjoining the Wash. This immigration and those of religious refugees from the Continent in later times have introduced into the population an element which has enabled the county to produce a large number of notable men. Linen was manufactured at Aylsham in the 14th century. Fuller, writing in the 17th century, describes Norfolk as abounding in all good things, and especially rabbits, herrings and worsteds. The leather industry flourished in Norman times.

The great variety of the soils in the county has helped to make it rich agriculturally, and where the land is not suitable for ploughing it is usually good for pasture. It was at Holkham, in this county, that Thomas Coke, earl of Leicester, carried out experiments in the cultivation of wheat and began to improve the standard of livestock in Britain. In 1926 the total acreage under crops and grass was 1,007,803, of which one-tenth was under wheat, nearly a fifth under barley, while oats occupied more than half the acreage of wheat. Rye covered 7,824, beans and peas

over 13,000 acres. The area of sugar beet was 32,384 ac., of potatoes 19,000 ac., and of root crops 127,381 acres. Clover and rotation grasses for hay occupied 115,503 ac., and orchards over 8,000 acres.

Industries, Communications, etc.—The weaving of silk and wool is still carried on at Norwich and also shawl weaving, although the staple trade of the town is now boots and shoes. Silk is also manufactured at Yarmouth, Wymondham and North Walsham. Flour-mills are numerous all over the county, and there are agricultural implement works at Norwich, Lynn, Thetford, East Harling, North Walsham, Walsingham and East Dereham. Lime-burning, brick-making, tanning, malting and brewing are carried on in various districts. There are extensive mustard and starch works at Norwich. The sea-coast is of a dangerous nature and there is a lack of harbours. A large trade, however, is carried on at Yarmouth, which is also famous for its herring fishery. The other principal port is Lynn, and there is a small trade at Wells.

The L.N.E. railway serves King's Lynn, Thetford, Norwich, Swaffham and Yarmouth, and has numerous branches. The M. and Gt.N.Jt. railway runs from Lynn to Cromer, Norwich and Yarmouth. The eastern rivers afford water communication with Great Yarmouth, while the Great and Little Ouse and some of the drainage cuts communicate with Lynn.

The area of the administrative county is 1,315,064 ac., with a population (1921) of 504,293. The municipal boroughs are—King's Lynn; Norwich, a city and county borough and the county town; Thetford; and Yarmouth, properly Great Yarmouth, a county borough. The county is in the south-eastern circuit, and assizes are held at Norwich. There are two courts of quarter sessions. Each of the four municipal boroughs has a separate court of quarter sessions. Norfolk is mainly in the diocese of Norwich, with small parts in those of Ely and Lincoln. For parliamentary purposes the county is divided into five divisions—King's Lynn, South-Western, Northern, Eastern and Southern—and also includes the parliamentary borough of Norwich (two members), and part of the parliamentary borough of Great Yarmouth (one member). Of the three boys' public schools in the county, two are in Norwich, viz., King Edward VI.'s school and the City of Norwich school. The third, Gresham's school, was founded at Holt, near Sheringham, in 1555, by Sir Thomas Gresham (*q.v.*).

Broads and Rivers.—The rivers and broads (lakes) of Norfolk, together with the few in Suffolk, form over 200 m. of navigable waterway. They are now, however, chiefly used by pleasure craft, though a diminishing number of trading wherries still carry coal and other goods between the large towns, such as Yarmouth, and the villages. The southern rivers are wider and deeper than the northern, and the Yare can be navigated by sea-going trading vessels as far as Norwich.

The formation of a broad may be due either to the widening of a river or to a sea-estuary becoming completely enclosed by sand-banks. The broads tend to become overgrown with reeds which, if they are not cut (they can be utilized to make a very durable thatch), rot and fall to the ground, and, aided by the general silting up, they may cause the broad to be replaced by dry land. Several of the broads have to be dredged to preserve a navigable channel, some of them (*e.g.*, Hickling broad) being extremely shallow.

Some of the broads are extremely beautiful; notably Wroxham, Salhouse and South Walsham (up the Bure), which are surrounded by wooded country; Barton broad (up the Ant); and Horsea mere (up the Thurne, not far from the sand dunes and near to Hickling broad), which is of quite a different character, being surrounded by reedy marshland, the haunt of hundreds of different species of wild birds. The bittern (*q.v.*) was saved from extinction at an island on Hickling broad, and now flourishes in considerable numbers. The bearded tit (*see* TITMOUSE) has also been saved from the same fate. The fishing is good, and wild duck are shot from a "Breydon duck-punt" which carries a heavy gun aimed by manoeuvring the boat itself.

Jessopp, Arcady (1887), and other works; Quarterly Review (1897), where other literature is cited; G. C. Davies, Norfolk Broads and Rivers (Edinburgh, 1884); Christopher Marlowe, People and Places in Marshland (1927).

NORFOLK, a city of Madison county, Nebraska, U.S.A., in the north-eastern part of the State, on the Elkhorn river, at an altitude of 1,525 feet. It is on Federal highway 81, and is served by the Chicago and North Western, the Chicago, St. Paul, Minneapolis and Omaha and the Union Pacific railways. The population was 8,634 in 1920 (88% native white) and was estimated locally at 12,500 in 1928. The city was founded in 1866, incorporated in 1881, and chartered in 1886.

NORFOLK, a seaport of Virginia, U.S.A., on the Hampton Roads. It is on Federal highways 17 and 117, and is served by the Atlantic Coast Line, the Chesapeake and Ohio, the Norfolk Southern, the Norfolk and Western, the Pennsylvania, the Seaboard Air Line, the Southern and the Virginian railways (all interconnected by an industrial belt line), and by interurban trolleys, motor-bus and trunk lines, several ferries and about 60 steamship lines. Pop. 115,777 in 1920 (108 males to 100 females, and 37% negroes); estimated at 184,200 in 1928.

The city has a land area of 27 sq.m. and 50 m. of water front on Hampton Roads, Chesapeake bay, the Elizabeth "river" (which is a tidal estuary, not a river), and the Lafayette river (another estuary). Immediately opposite is the city of Portsmouth. The town of Berkley was annexed to Norfolk in 1906, and lying beyond it is the still independent town of South Norfolk.

The waters about Norfolk, Portsmouth and Newport News (officially known as the Port of Hampton Roads, and under the jurisdiction of the State Port Authority created in 1926) form one of the finest natural harbours of the world, where a thousand ships at a time have found berthing space or anchorage without taxing its capacity. The part known as Norfolk harbour (which includes the Portsmouth waters) is 15.5 m. long, varies from $\frac{1}{2}$ to 2 m. in width, and is connected with the bay by a 40 ft. channel. On the Norfolk water front there are 154 piers, largely owned by railroads, steamship lines and ship-building companies. The army supply base, north of the Lafayette river, established in 1917 and representing an investment of \$30,000,000, was leased by the city from the United States in 1919, and beyond it a modern municipal terminal has been constructed (at an expenditure of \$6,000,000) including a grain elevator with a capacity of 800,000 bushels, a dock specially equipped for shipping garden and farm produce and a general merchandise pier 1,210 ft. long, with transit sheds and warehouses. The business section of the city is compactly built up with hotels, stores and office-buildings that seem tall in proportion to the width of the streets.

Some beautiful ante-bellum homes and interesting old buildings remain, including St. Paul's church (1737) which has a British cannon-ball embedded in its walls; the Old Norfolk academy (built in 1840), now used temporarily by the juvenile and domestic relations court; and the colonnaded city hall (1847). There are public parks covering 500 ac., 22 playgrounds, 40 public-school buildings, 181 churches, 2 newspapers, a public library with six branches, a municipal market built in 1923 at a cost of \$500,000 and a picturesque municipal armoury, around which an open-air flower market is held the year round. Virginia beach, a popular resort on the Atlantic, 5 m. below Cape Henry, is 20 m. east of Norfolk, and there are many other recreation spots in the vicinity. The water-supply, sufficient for a much larger city, comes partly from works built in 1872-73, which for some time had been seriously inadequate, and partly from Lake Prince (20 m. W.) through a new system constructed since 1920 at a cost of \$6,000,000. Since 1919 the city has operated under a commission-manager form of government. The assessed valuation for 1927 was \$175,818,039.

Norfolk is the centre of many activities of the Federal Government. The Norfolk navy yard is on the Portsmouth side of the Elizabeth river (*see* PORTSMOUTH), and the naval hospital is also in Portsmouth. In Norfolk (directly opposite the navy yard) is the St. Helena naval reservation, now used as a naval air-landing

field. Within the city are also a U.S. Public Health Service hospital, a branch of the U.S. Hydrographic Office, district headquarters of the Coast Guard; headquarters of the customs district of Virginia and various other offices. At Sewall point, on the northern edge of Norfolk, is the Hampton Roads naval operating base, comprising a training station where nearly 50,000 men were trained for the navy during the World War; a supply station with warehouse floor-space of 55 ac. and the navy's principal fuel-reserve depot; a naval air station and a submarine base.

Since the opening of the World War, Hampton Roads has become one of the important ports of the United States in respect of foreign trade, handling in 1925 5,644,675 tons of imports and exports, over 5% of the total of the country. More than half the tobacco exported from the United States moves through Hampton Roads, and in 1927 the railroads dumped altogether 19,816,806 tons of coal at this port, for coastwise and foreign trade and for bunkering purposes. It is also an important oil-bunkering port, with a storage capacity of 2,500,000 barrels. About $\frac{1}{3}$ of the total tonnage of Hampton Roads moves through the Norfolk harbour. Norfolk is surrounded by one of the finest truck-farming districts of the United States, and is the shipping point for immense quantities of potatoes, spinach, kale, beans, cauliflower, tomatoes and strawberries. Norfolk's industries had an output in 1925 valued at \$35,454,752. Shipbuilding is perhaps the most important. Among products are fertilizers (1,000,000 tons a year), peanut and cotton seed oil, sea-foods, textiles, automobiles, cement and lumber.

Norfolk was laid out in 1688 (on 50 ac. of land bought from Nicholas Wise, a carpenter, for 10,000 lb. of tobacco) to be a centre of trade, and was incorporated as a borough in 1736. On Jan. 1, 1776, it was furiously bombarded by the British under Lord Dunmore. Sailors set fire to the warehouses along the water front, and the town burned for three days, until all the buildings except St. Paul's church were destroyed. After the Revolution it was rebuilt, and grew rapidly until the Embargo Act of 1807 ruined its commerce at a single stroke. In the War of 1812 Norfolk was attacked and successfully defended. It was chartered as a city in 1845. In 1855 there was a disastrous epidemic of yellow fever, brought in by a man-of-war. At the outbreak of the Civil War Norfolk had a population of 14,620. The navy yard was burned and abandoned by the Federals in April 1861, and the city was held by the Confederates until May 10, 1862. Recovery after the war was gradual until 1880, when the population was 21,966. After that growth was more rapid, to 34,871 in 1890, 46,624 in 1900, and 67,452 in 1910. The Ter-Centennial Exposition, celebrating the founding of Jamestown, was held here in 1907, on ground now within the city limits and occupied by the naval base. During the World War Norfolk had a period of intoxicating prosperity, due at first to heavy shipments of orders to the Allies, and after 1917 to the activities at the army supply base and the naval operating base and navy yard. Correspondingly severe was the post-war deflation, when the army base was closed down, the fleet transferred to the Pacific coast and the naval training station reduced to a skeleton organization; but in the following years substantial foundations were laid for a healthy commercial, civic and industrial development.

NORFOLK AND WESTERN RAILWAY COMPANY, THE, primarily a coal carrier, with a total investment of \$425,614,646.55 and a total capitalization of \$162,998,600 on Dec. 31, 1927, employed in 1928, 30,000 persons and operated 4,477 m. of track in six States in the United States, namely: Virginia, West Virginia, North Carolina, Maryland, Ohio, and Kentucky. Its main line runs from Norfolk and Lambert Point, Va., the eastern terminus, on the Port of Hampton Roads, through agricultural, livestock and mineral sections of Virginia, through vast coal fields in West Virginia and thence into Ohio to Cincinnati and Columbus, the western terminals. A line from Roanoke, Va., to Hagerstown, Md., makes connections for the east and north; two lines into North Carolina, one from Roanoke, Va., to Winston-Salem and the other from Lynchburg, Va., to Durham, make connections with the south. One of the first railroads in the country to employ electric traction, the N. and W. greatly increased its

operating efficiency by electrifying 210 m. of track on mountain grades in West Virginia. The coal traffic of the road has grown from 70,000 tons in 1883 to almost 43,000,000 tons in 1927.

The road had its beginning in Virginia in 1837 as the City Point Railroad running between Petersburg and City Point, a distance of ten miles. The South Side (which purchased the City Point), Norfolk and Petersburg, and Virginia and Tennessee railroads, all in Virginia and built between 1849 and 1858, running from Norfolk to the Tennessee line at Bristol, consolidated in 1870 as the Atlantic, Mississippi and Ohio R.R. Co., with a total trackage of 479 miles. This road was sold in 1881 and became the Norfolk and Western Railroad Company. Between 1881-91 it built three lines into the coal fields of Virginia and West Virginia extending beyond to Ohio and acquired by purchase two other roads, one running from near Ironton, Ohio to Columbus, and the other, from Roanoke to Hagerstown. In Sept. 1896, the railroad was organized as the Norfolk and Western Railway Company. Later in the year it purchased the two lines running from Virginia into North Carolina. In 1901 it bought a second line in Ohio, from Sciotoville to Cincinnati. Since that time the road has had a steady development, with double tracking, branch construction and the complete modernization of all its facilities. (A. C. N.)

NORFOLK ISLAND: see PACIFIC ISLANDS.

NORICUM, a district south of the Danube, corresponding to part of Styria and Carinthia, Austria, Bavaria and Salzburg. The population was Illyrian afterwards subordinate to various Celtic tribes. The country is mountainous and the soil poor, but it was rich in iron, and the famous Noric steel was used for Roman weapons. The inhabitants were warlike and paid more attention to cattle-breeding than to agriculture. Gold and salt were found in considerable quantities; the wild nard grew in abundance, and was used as a perfume. Noricum was the southern outpost of the Celtic peoples and the starting-point of their attacks upon Italy. The cemeteries of Hallstatt (*q.v.*), less than 40m. from Noreia, contained weapons and ornaments from the bronze age up to the fully developed iron age. Prof. Ridgeway (*Early Age of Greece*, i. ch. v.), holds that here was the cradle of the Homeric Achaeans. For a long time the Noricans enjoyed independence under princes of their own, and carried on commerce with the Romans. In 16, having joined with the Pannonians in invading Histria, they were defeated by Publius Silius, proconsul of Illyricum. From this time Noricum was called a province, although not organized as such, but remaining a kingdom with the title *regnum Noricum*, under the control of an imperial procurator. In the reign of Marcus Antoninus the Legio II. Pia was stationed at Noricum, and the commander of the legion became governor.

Peaks, *The General Civil and Military Administration of Noricum and Raetia* (Chicago, 1907); full references to ancient authorities in A. Holder, *All-celtischer Sprachschatz*, ii. (1904).

NORMAL SCHOOLS: see TEACHERS, TRAINING OF.

NORMAN, SIR HENRY WYLIE (1826-1904), field-marshal and colonial governor, was born on Dec. 2, 1826, and entered the Indian army at the age of seventeen. Norman served in numerous frontier campaigns between 1850 and 1854, and in the suppression of the Sonthal rebellion of 1855-56. In the Mutiny campaign he was constantly engaged, being present at the siege of Delhi, the relief of Lucknow and a number of other affairs. As adjutant-general of the Delhi Field Force, he was one of the leading spirits of the siege, and afterwards became its chief chronicler. Altogether he was mentioned twenty-five times in despatches. He held various important positions at Simla and at Whitehall until 1883. He was then governor of Jamaica (1883-88), governor of Queensland (1888-95), agent-general for Queensland, and in 1901 governor of the Royal Hospital, Chelsea. In 1902 he was made a field-marshal. He died on Oct. 26, 1904.

See Sir William Lee Warner, *Memoirs of Field-marshal Sir Henry Wylie Norman* (1908).

NORMAN, MONTAGU COLLET (1871-), British financier, was educated at Eton and King's college, Cambridge. He served in the South African War, 1900-01 and was awarded

the D.S.O. He afterwards became connected with the financial side of business, and his active association with the Bank of England began during the World War. In 1918 he was appointed deputy-governor and in 1920 governor of the Bank of England. He was re-elected for the seventh time in 1926, having held the post for longer than any previous governor. In 1922 he accompanied Mr. Baldwin, then chancellor of the exchequer, to the United States to arrange for the funding of the British war debt. During his governorship the gold standard was restored. In 1923 he was made a privy councillor.

NORMAN, a city of central Oklahoma, U.S.A., 18 m. S. of Oklahoma City, on a plateau 1,170 ft. above sea-level, overlooking the valley of the South Canadian river; county seat of Cleveland county. It is on Federal highway 77, and is served by the Oklahoma and the Santa Fe railways. Pop. (1920) 5,004 (98% native white) estimated locally at 10,000 in 1928. It is the seat of the University of Oklahoma (opened in 1892) with 5,000 students in winter and 2,500 in summer; and of the State Hospital for mental diseases, with 1,400 patients. The university occupies a campus of 177 acres. Its grounds and buildings are valued at about \$4,000,000; its revenues for the year ending June 30, 1927, were \$1,418,465. The faculty numbers about 280. Norman was founded in 1889 and chartered as a city in 1902. Since 1919 it has had a commission-manager form of government.

NORMAN, in architecture, the Romanesque style developed in Normandy and England during the 11th and 12th centuries, up to the time of the general adoption of Gothic architecture in both countries. As it was only shortly before the Norman conquest of England that Normandy became settled and civilized enough to produce an architecture, the origin in both countries is the same, and early types extremely similar. This common early Norman differed from Romanesque in its love of geometric ornament such as zig-zags, general crudeness in carving figures and leaves, and a daring originality in construction ideas, probably owing much to the fact that Lanfranc of Pavia (d. 1089) had introduced Lombard ideas into many Norman abbeys.

Although the English and French phases of the style were thus identical at the start, they soon became different. The French was characterized by careful, structural articulation (Abbaye-aux-Dames and Abbaye-aux-Hommes, Caen, both founded in 1062, but altered later), and elaboration of tower and spire (S. Michel de Vauelles, Caen, 12th century). In England the chief characteristics are enormous length of church plan, the frequent use of great round columns for the nave arcade (Gloucester cathedral, 1089-1100; Tewkesbury abbey, 1123; and Durham cathedral, alternate piers, 1099-1128) and great decorative richness (Prior's door, Ely cathedral, late 12th century; S. Mary's chapel, Glastonbury abbey, 1186; the front of Ilfley church, 12th century; and the Galilee porch at Durham, c. 1175). The general Norman structural genius is most markedly shown in the ribbed vault of Durham cathedral, whose date is much debated, being placed as early as 1133 and as late as the 13th century. (See BYZANTINE AND ROMANESQUE ARCHITECTURE.)

NORMANBY, CONSTANTINE HENRY PHIPPS, 1ST MARQUESS OF (1797-1863), British statesman and author, son of Henry, 1st earl of Mulgrave (1755-1831), was born on May 15, 1797. The 1st earl (who was created baron in 1794 and earl in 1812) was a distinguished soldier, and Pitt's chief military adviser; and he held the offices of chancellor of the duchy of Lancaster (1804), secretary for foreign affairs (1805), first lord of the admiralty (1807-10), and master of the ordnance (1810-18). In 1792 he inherited the earlier Irish barony of Mulgrave—created in 1767 for his father, Constantine (1722-75) grandson of Sir Constantine Phipps (1656-1723), the lord chancellor of Ireland—from his elder brother Constantine (1744-92), a naval captain.

His son, the 1st marquess, was governor of Jamaica (1830-35) and lord-lieutenant of Ireland (1835-39). He was created marquess of Normanby in 1838, and held successively the offices of colonial secretary and home secretary in the last years of Lord Melbourne's ministry. From 1846 to 1852 he was ambassador at Paris, and from 1854 to 1858 minister at Florence. The publication in 1857 of a journal kept in Paris during the stormy

times of 1848 (*A Year of Revolution*), brought him into violent controversy with Louis Blanc, and he came into conflict with Palmerston and Gladstone, on French and Italian policy. He died on July 28, 1863. He was succeeded as 2nd marquess by his son George (1819-90), a liberal statesman, who became governor of Queensland (1871-74), New Zealand (1874-79), and Victoria (1879-84).

NORMANDY, a province of old France, bounded on the N.E. by the river Bresle, which falls into the Channel at Tréport and separates Normandy from Picardy, and then roughly by the Epte, which divides the Vexin into two parts.

Under the feudal régime, the energy of the Norman dukes prevented the formation of many powerful lordships, and there are few worthy of note, save the countships of Eu, Harcourt, Le Perche and Mortain. The duchy of Normandy, which was confiscated in 1204 by King Philip Augustus of France, formed in the 16th century the *gouvernement* of Normandy; the extent of this *gouvernement* did not, as a matter of fact, correspond exactly to that of the duchy, for Le Perche, which had been part of the duchy, was annexed to the *gouvernement* of Maine, while the Thimerais, which had belonged to the countship of Blois, was joined to the *gouvernement* of Normandy. In the 17th century this *gouvernement* was divided into three *généralités* or *intendances*: those of Rouen, Caen and Alençon. For judicial purposes Normandy was under the jurisdiction of the parlement of Rouen, created in 1499. Since 1791 the territory of the old duchy has composed, roughly speaking, the departments of Seine-Inférieure, Eure, Calvados, Manche and Orne.

History.—The province of *Lugdunensis Secunda*, which included Normandy, was conquered by Clovis before 506, and during the Merovingian times followed the fortunes of Neustria. In the 9th century this country was ravaged by the Northmen, and at length was formally ceded to them. The definitive establishment of the Normans, to whom the country owes its name, took place in 911, when by the treaty of Saint-Clair-sur-Epte, concluded between King Charles the Simple of France and Rollo, chief of the Normans, the territory comprising the town of Rouen and a few *pagi* situated on the sea-coast was ceded to the latter. Later, Rollo received from the king of France Bessin and Maine. Although baptized, he seems to have retained many pagan customs. The legend that he married Gisela, daughter of Charles the Simple seems to be unfounded.

History is here obscure. The first two dukes, Rollo and his son William "Longsword," displayed a certain fidelity to the Carolingian dynasty, and in 936 William did homage to Louis IV. d'Outremer. He died on Dec. 17, 942, assassinated by the count of Flanders. During the minority of his successor, Duke Richard, King Louis IV., who was making an expedition into Normandy, was captured by the inhabitants of Rouen and handed over to Hugh the Great. From this time onwards the dukes of Normandy began to enter into relations with the dukes of France; and in 958 Duke Richard married Hugh the Great's daughter. He died in 996. At the beginning of the reign of his son, Richard II. (996-1026), there was a rising of the peasants, who formed assemblies with a view to establishing fresh laws for the management of the forests. This attempt at insurrection, described by William of Jumièges, and treated by many historians, on the authority of the poet Wace, as a sort of democratic movement, was put down with an iron hand. Richard III. reigned from 1026-27 and Robert the Magnificent or the Devil (1027-35). In 1031 Robert supported King Henry I. of France against his brother Robert, who was laying claim to the throne, and in return for his services received the French Vexin. The duke died on a pilgrimage to Jerusalem, leaving as his heir an illegitimate son, William, born of his union with the daughter of a tanner of Falaise and left under the protection of the king. In 1047 Henry I. had to defend the young duke against an army of rebellious nobles, whom he succeeded in beating at Val-ès-dunes. In the following year the king of France was in his turn supported by the duke of Normandy in his struggle against Geoffrey Martel, count of Anjou; the two allies besieged Moulherne (1048); and the war was continued between the duke of Normandy and the count of Anjou by the

siege of Alençon, which was taken by Geoffrey Martel, then retaken by William, and that of Domfront, which in 1049 had to surrender to Duke William.

In 1054 the duke married Matilda, daughter of Baldwin V., count of Flanders. The king of France before long became alarmed at William's ambitions, and encouraged William Busac, count of Eu and Montreuil, in his claim to the ducal crown. In 1054 he invaded Normandy with his brother Odo and this count, but Odo was beaten at Mortemer. In 1058 the king of France, joined by Geoffrey Martel, count of Anjou, tried to revenge himself, but was beaten at the ford of Varaville.

Towards the same time occurred the temporary annexation of Maine to Normandy. Herbert II., the young count of Maine, who was a vassal of the count of Anjou, did homage to William between 1055 and 1060, perhaps after the defeat of Geoffrey Martel; he promised to marry one of William's daughters, and betrothed his sister Margaret to the duke's son, Robert Curthose, on the understanding that, if he died leaving no children, the countship was to fall to William. After his death, the people of Maine revolted (1063), choosing as their lord Walter of Mantes, count of Vexin; but William, after one campaign, succeeded in imposing Norman authority. Three years later, he took possession of England, of which he was crowned king in 1066. Normandy now became the scene of William's quarrels with his son, Robert Curthose, who laid claim to Normandy and Maine, and with the aid of King Philip I. of France succeeded in defeating his father at Gerberoi in 1079.

After the death of William (Sept. 7, 1087), his eldest son, Robert Curthose, kept Normandy and Maine, and his second son, William Rufus, became king of England. In 1096 Robert departed on a crusade and pledged the duchy to his brother for 10,000 livres. When Robert returned, William Rufus had just died, and his youngest brother, Henry, had already taken possession of the crown. Henry was ambitious of uniting Normandy to England; in 1105, with the aid of Helias, count of Maine, and the son of Geoffrey Martel, count of Anjou, he took and burnt Bayeux, but failed to take Falaise. On Sept. 28, 1106, he defeated his brother at Tinchebrai, took him prisoner, and seized Normandy. Thus the centre of gravity was changed; England had at first been dependent on Normandy, Normandy was now subordinate to England.

Union with England.—From 1106 to 1204 Normandy remained united to England. Henry I. carried on hostilities against the king of France and William Clito, son of Robert Curthose, whose claim to the duchy of Normandy was upheld by Louis VI., and won an important victory over his opponents at Brémule (1119). After the disaster of the White Ship (1121), in which the Atheling William lost his life, Henry's only surviving child was a daughter, Matilda, widow of the emperor Henry V. In 1127 Matilda married Geoffrey the Fair, eldest son of Fulk V., count of Anjou. After the death of Henry I. in 1135, a struggle arose between Matilda, who claimed the kingdom of England and the duchy of Normandy in the name of her son Henry, and Theobald, count of Champagne, grandson of William the Conqueror on the side of his mother Adela, the candidate of the Normans of Normandy, while the Norman party in England supported Stephen, brother of Theobald. In 1144 Theobald, whose position had been much weakened since the taking of the castle of Rouen, gave up his rights in Normandy to Matilda's husband Geoffrey, count of Anjou, in favour of Henry Plantagenet. Between 1139 and 1145 Geoffrey, with French and Flemish help, gradually subdued Normandy, and on his death, in 1151, his son Henry Plantagenet was master of Normandy as well as count of Anjou. In 1152, by his marriage, Aquitaine also was secured to himself and his descendants, and in 1153 he was recognized as heir to the throne of England. The duchy of Normandy, though nominally in feudal dependence on the king of France, thus became part of the great Angevin empire, of which the power and resources were more than equal to that of the French kings (*see* FRANCE: *History*, and ENGLISH HISTORY).

From the first the French kings were fully conscious of the menace of the Angevin power. The reign of Louis VII. was occupied by the struggle against Henry II. Philip Augustus (1180–

1223) pursued the same policy with greater tenacity and success. He began by taking part against Henry II. with his son and successor, Richard, who obtained the throne on the death of Henry II. in 1189. From the point of view of Normandy, the most important events of Richard's reign were: the truce of Issoudun, by which Philip Augustus kept the Norman Vexin which he had just conquered (1195), the building by Richard of Château-Gaillard (1196), and finally the defeat of Philip Augustus by Richard at Courcelles, near Gisors (1198). On the death of Richard at Chalus in 1199 the position of Philip Augustus was critical. The situation was modified under the reign of John Lackland, Richard's brother, who had himself crowned duke of Normandy at Rouen (April 25, 1199). Philip Augustus set up in opposition to him Arthur of Brittany, son of Geoffrey and grandson of Henry II., and the first phase of the struggle between the kings of France and England continued until the treaty of Goulet (1200). But in 1202 Philip made a fresh attempt to seize the Continental possessions of the kings of England. An excuse for reopening hostilities offered itself in the abduction, by John, of Isabel of Angoulême, the betrothed of Hugh le Brun, son of the count of La Marche. The barons appealed to Philip Augustus, who summoned John to appear before the royal judges; he failed to appear, and was consequently condemned by default, as a disloyal vassal, to have all the fiefs which he held in France confiscated (April 1202). The confiscation, a purely formal operation, was followed by the actual conquest.

In June 1202 Philip Augustus invaded Normandy and besieged the castle of Arques, near Dieppe; at the same time Arthur of Brittany was taken prisoner by John at Mirebeau in Poitou, and imprisoned in the castle of Falaise, from which he was removed to Rouen and died, probably assassinated by John's orders. The conquest of Normandy began with the occupation of Château-Gaillard after an eight months' siege (Sept. 1203–April 1204); the rest of Normandy was taken during the following months, Rouen surrendering in 1204 but obtaining a guarantee of her privileges. The conquest of Normandy by the French was not, however, recognized officially till the treaty of Paris (1259). In 1329 the duchy of Normandy was revived in favour of John, son of King Philip VI.

The Hundred Years' War.—Owing to her geographical position, Normandy suffered heavily during the Hundred Years' War. In 1346 Edward III., at the instance of Godefroi d'Harcourt lord of Saint-Sauveur, invaded Normandy, landing at Saint-Vast-la-Hougue (July 12); and arriving at Caen on July 25, he laid waste the country as far as Poissy. After the accession of John II. (1350), Normandy was given as an appanage to the dauphin Charles. The treaty of London (1359) stipulated for its cession to England, but the provisions of the treaty were modified by those of the treaty of Brétigny (1360), and it remained in the possession of France.

The most striking event of the war in Normandy during the reign of Charles V. (1364–80), was the siege of Saint-Sauveur-le-Vicomte, which was occupied by the English, and only surrendered after a siege of several years. The opening years of the reign of Charles VI. (1380–1422) were disturbed by a revolt which broke out in Rouen against the *aides* which the royal Government had tried to impose (1381). In 1415 the war with England was resumed: an English army of 60,000 men landed on Aug. 14 at the mouth of the Seine, took Harfleur on Sept. 16, and finally defeated the army of the king of France at Agincourt. During the following years the whole of Normandy was occupied, Rouen holding out for nearly six months (July 29, 1418–Jan. 13, 1419), and Henry V. of England entrusted the administration of Normandy to a special council. After the expeditions of Joan of Arc and the treaty of Arras the position of the English in Normandy became insecure; at the end of 1435 the whole district of Caux, and in 1436 that of the Val de Vire revolted; Mont-Saint-Michel, which had never been taken by the English, continued to resist, and in order to keep guard over it the English built Granville. But Normandy was not recovered by the French till after the sack of Fougères (1449). Cotentin was reconquered by Richmond (*see* ARTHUR, duke of Brittany) and the duke of Brittany;

Rouen surrendered on Oct. 29, 1449. An English army was sent into Normandy under the leadership of Thomas Kyriel; it landed at Cherbourg and marched across Cotentin to Bayeux, but was met at Formigny (April 15, 1450) by the count of Clermont and utterly routed. Caen, and finally Cherbourg, capitulated.

After the French conquest, the history of Normandy is less eventful. The kings of France maintained the provincial Estates and the University of Caen, founded by the kings of England, and transformed the Exchequer of Normandy into a permanent court of justice (1499) which was called the parlement of Normandy. Among the measures which contributed to the increase of the prosperity of Normandy should be noted the construction in 1752 of the Hâvre de Grace.

During the 16th century the Protestant Reformation met with some success in Normandy. The Reforming movement began with Pierre Bar in 1528, and the first apostle of the Reformation at Rouen was François Legay, called Boissnormand. Caen received the Reformed religion in 1531, and Alençon in 1582. In the massacre of St. Bartholomew's day (1572) more than 500 victims were slaughtered by the Catholics. After 1588 the Catholic party of the League established itself in Normandy, and King Henry IV. had to conquer it by force of arms. The most famous engagements during this expedition were the king's victories at Arques and Ivry, but he failed to take Rouen, which was defended by Alexander Farnese, duke of Parma, and only surrendered after the abjuration of the king.

(R. LA.; F. M. S.)

NORMANS, the softened form of the word "Northman," applied first to the people of Scandinavia in general, and afterwards specially to the people of Norway. In the form of "Norman" it is the name of those colonists from Scandinavia who settled in Gaul, founded Normandy, adopted the French tongue and French manners, and from their new home set forth on new errands of conquest, chiefly in the British islands and in southern Italy and Sicily. Normans and Northmen must be carefully distinguished. For these Normans began to adopt a new religion, a new language, a new system of law and society, new thoughts and feelings on all matters. To all outward appearance the Norman conquest of England was an event of an altogether different character from the Danish conquest. The one was a conquest by a people whose tongue and institutions were still palpably akin to those of the English. The other was a conquest by a people whose tongue and institutions were palpably different from those of the English. The Norman settlers in England felt no community with the earlier Danish settlers in England. In fact the Normans met with the steadiest resistance in a part of England which was largely Danish. But the effect of real, though unacknowledged, kindred had none the less an important practical effect. There can be no doubt that this hidden working of kindred between conquerors and conquered in England, as compared with the utter lack of all fellowship between conquerors and conquered in Sicily, was one cause which made so wide a difference between the Norman conquests of England and of Sicily.

Character of the Normans.—The English and the Sicilian settlements form the main Norman history of the 11th century. The new creed, the new speech, the new social system, had taken such deep root that the descendants of the Scandinavian settlers were better fitted to be the armed missionaries of all these things than the neighbours from whom they had borrowed their new possessions. With the zeal of new converts they set forth very much in the spirit of their heathen forefathers. The same spirit of enterprise which brought the Northmen into Gaul seems to carry the Normans out of Gaul into every corner of the

world. Their character is well painted by a contemporary historian of their exploits, Geoffrey Malaterra. He sets the Normans before us as a race specially marked by cunning, despising their own inheritance in the hope of winning a greater, eager after both gain and dominion, given to imitation of all kinds, holding a certain mean between lavishness and greediness—i.e., perhaps uniting, as they certainly did, these two seemingly opposite qualities. Their chief men, he adds, were specially lavish through their desire of good report. They were, moreover, a race skilful in flattery, given to the study of eloquence, so that the very boys were orators, a race altogether unbridled unless held firmly down by the yoke of justice. They were enduring of toil, hunger, and cold whenever fortune laid it on them, given to hunting and hawking, delighting in the pleasure of horses, and of all the weapons and garb of war. Love of imitation is marked. Little of original invention can be traced to any strictly Norman source; but no people were ever more eager to adopt from other nations, to take into their service and friendship from any quarter men of learning and skill and eminence of every kind. To this admirable quality is perhaps to be attributed the fact that a people who accomplished so much, who settled and conquered in so large a part of Europe, has practically vanished from the face of the earth.

Their Faculty of Adaptation.—But Geoffrey hardly did justice to the Normans if he meant to imply that they were simple imitators of others. Their position was very like that of the Saracens. In no department of science or art did any Saracen, strictly speaking, invent anything; but they learned much both from Constantinople and from Persia, and what they learned they largely developed and improved. The Normans did just the same. They adopted the French tongue, and were presently among the first to practise and spread abroad its literature. They adopted the growing feudal doctrines of France, and worked them, both in Normandy and in England, into a harmonious system. From northern Italy, as it would seem, they adopted a style of architecture which grew in their hands, both in Normandy and in England, into a marked and living form of art. Settled in Gaul, the Scandinavian from a seafaring man became a landsman. Even in land-warfare he cast aside the weapons of his forefathers; but he soon learned to handle the weapons of his new land with greater prowess than they had ever been handled before. He welcomed the lore of every stranger. Lanfranc brought law and discipline; Anselm brought theology and philosophy. The gifts of each were adopted and bore fruit on both sides of the Channel. And no people ever better knew how to be all things to all men. The Norman power in England was founded on full and speedy union with the one nation among whom they found themselves. The Norman power in Sicily was founded on a strong distinction between the ruling people and the many nations which they kept in peace and prosperity by not throwing in their lot with any one among them.

The quality which Geoffrey Malaterra expresses by the word "effrenatissima" is also clearly marked in Norman history. It is, in fact, the groundwork of the historic Norman character. It takes in one case the form of ceaseless enterprise, in another the form of that lawlessness which ever broke out, both in Normandy and in every other country settled by Normans, when the hand of a strong ruler was wanting. But it was balanced by another quality which Geoffrey does not speak of, one which is not really inconsistent with the other, one which is very prominent in the Norman character, and which is, no less than the other, a direct heritage from their Scandinavian forefathers. This is the excessive litigiousness, the fondness for law, legal forms, legal processes, which has ever been characteristic of the people. If the Norman was a born soldier, he was also a born lawyer. But nothing so well illustrates this formal side of the Norman character as the whole position of William the Conqueror himself. His claim to the crown of England is something without earlier precedent, something as far as possible removed from the open violence of aggressors who have no pretexts with which to disguise their aggression. It rested on a mass of legal assumptions and subtleties, fallacious indeed, but ingenious, and, as the result proved,

effective. His whole system of government, his confiscations, his grants, all that he did, was a logical deduction from one or two legal principles, arbitrary certainly in their conception, but strictly carried out to their results. Even Norman lawlessness in some sort took a legal shape. In the worst days of anarchy, in the minority of William or under the no-reign of Robert, the robber-baron could commonly give elaborate reasons for every act of wrong that he did.

The Normans were, therefore, crusaders before crusades were preached. Norman warriors had long before helped the Christians of Spain in their warfare with the Saracens of the Peninsula, and in Sicily it was from the same enemy that they won the great Mediterranean island. Others had done a kindred work in a more distant field as helpers of the Eastern emperors against the Turks of Asia. All these might pass for religious wars, and they might really be so; it needed greater ingenuity to set forth the invasion of England as a missionary enterprise designed for the spiritual good of the benighted islanders. The Norman, a strict observer of forms in all matters, attended to the forms of religion with special care. No people were more bountiful to ecclesiastical bodies on both sides of the Channel; the foundation of a Benedictine monastery in the 11th century, of a Cistercian monastery in the 12th seemed almost a matter of course on the part of a Norman baron. On the other hand, none were less inclined to submit to encroachments on the part of the ecclesiastical power, the Conqueror himself least of all.

Neither England nor Sicily has become a Norman land, and the tongue which the Norman brought with him into both has not for ages been spoken in either. Norman influence has been far stronger in England than in Sicily, and signs of Norman presence are far more easily recognized. But the Norman, as a distinct people, is as little to be seen in the one island as in the other, a result due to different and almost opposite causes. The whole circumstances of the conquest of England constrained the conquerors to become Englishmen in order to establish themselves in the conquered land. In William's theory, the forcible conquest of England by strangers was an untoward accident. The lawful heir of the English crown was driven against his will to win his rights by force from outside. But he none the less held his crown as an English king succeeding according to English law. Moreover, every Norman to whom he granted lands and offices held them by English law in a much truer sense than the king held his; he was deemed to step into the exact position of his English predecessor, whatever that might be. This legal theory worked together with other causes to wipe out all practical distinction between the conquerors and the conquered in a wonderfully short time. By the end of the 12th century the Normans in England might fairly pass as Englishmen, and they had largely adopted the use of the English language. The fashionable use of French for nearly two centuries longer was far more a French fashion than a Norman tradition. When the tradition of speaking French had all but died out, the practice was revived by fashion. Still the tradition had its effect. The fashion could hardly have taken root except in a land where the tradition had gone before it.

The Normans in England therefore became Englishmen, because there was an English nation into which they could be absorbed. The Normans in Sicily could hardly be said to become Sicilians, for there assuredly was no Sicilian nation for them to be absorbed into. While the Normans in England were lost among the people of the land, the Normans in Sicily were lost among their fellow-settlers in the land. The Normans who came into Sicily must have been much less purely Norman than the Normans who came into England. Indeed, we may doubt whether the Norman invaders of Sicily were Norman in much more than being commanded by Norman leaders. They were almost as little entitled to be called pure Scandinavians as the Saracens whom they found in the island were entitled to be called pure Arabs. The conquest of England was made directly from Normandy, by the reigning duke, in a comparatively short time, while the conquest of Sicily grew out of the earlier and far more gradual conquest of Apulia and Calabria by private men. The Norman settlements at Aversa and Capua were the work of adventurers, making their own

fortunes and gathering round them followers from all quarters. They fought simply for their own lands, and took what they could by the right of the stronger. They started with no such claim as Duke William put forth to justify his invasion of England; their only show of legal right was the papal grant of conquests that were already made. The conquest of Apulia, won bit by bit in many years of what we can only call freebooting, was not a national Norman enterprise like the conquest of England, and the settlement to which it led could not be a national Norman settlement in the same sense. The Sicilian enterprise had in some respects another character. By the time it began the freebooters had grown into princes. Still there was a wide difference between the duke of the Normans and the duke of Apulia, between an hereditary prince of 150 years' standing and an adventurer who had carved out his duchy for himself.

The characteristic point of Norman rule in Sicily is that it is the rule of princes who were foreign to all the inhabitants of the island, but who were not more foreign to the inhabitants of the island than different classes of them were to one another. The Norman conqueror found in Sicily a Christian and Greek-speaking people and a Muslim and Arabic-speaking people. The relations between the two differed widely in different parts of the island, according to the way in which the Saracens had become possessed of different towns and districts. In one place the Christians were in utter bondage, in another they were simply tributary; still, everywhere the Muslim Saracen formed the ruling class, the Christian Greek formed the subject class. We speak of the Saracen very much as we speak of the Norman; for of the Muslim masters of Sicily very many must have been only artificial Arabs, Africans who had adopted the creed, language and manners of Arabia. In each case the Arab or the Norman was the kernel, the centre round which all other elements gathered and which gave its character to the whole. Besides these two main races, Greek and Saracen, others came in through the Norman invasion itself. There were the conquerors themselves; there were the Italians, in Sicily known as Lombards, who followed in their wake; there were also the Jews, whom they may have found in the island, or who may have followed the Norman into Sicily, as they certainly followed him into England. The special character of Norman rule in Sicily was that all these various races flourished, each in its own fashion, each keeping its own creed, tongue and manners, under the protection of a common sovereign, who belonged to none of them, but who did impartial justice to all. Such a state of things might seem degradation to the Muslim, but it was deliverance to the native Christian, while to settlers of every kind from outside it was an opening such as they could hardly find elsewhere. But the growth of a united Sicilian nation was impossible; the usual style to express the inhabitants of the island is "omnes" or "universi Siciliæ populi." In the end something like a Sicilian nation did arise; but it arose rather by the dying out of several of the elements in the country, the Norman element among them, than by any such fusion as took place in England.

Normans in Scotland, Wales and Ireland.—From England, the Norman spread into Scotland, Wales and Ireland. In Scotland he was not a conqueror, but a mere visitor, and oddly enough he came as a visitor along with those whom he had himself overcome in England. Both Normans and English came to Scotland in crowds in the days of Margaret, Edgar and David, and Scottish national feeling sometimes rose up against them. In Scotland again the Norman settlers were lost in the mixed nationality of the country, but not till they had modified many things in the same way in which they modified things in England. They gave Scotland nobles and even kings; Bruce and Balliol were both of the truest Norman descent; the true Norman descent of Comyn might be doubted, but he was of the stock of the Francigenæ of the Conquest. In Wales the Norman came as a conqueror, more strictly a conqueror than in England; he could not claim Welsh crowns or Welsh estates under any fiction of Welsh law. The Norman settler in Wales, therefore, did not to any perceptible extent become a Welshman. In Ireland the Norman was more purely a conqueror than anywhere else; but in Ireland his power of adaptation caused him to sink in a way in

which he sank nowhere else. While some of the Norman settlers in Ireland went to swell the mass of the English of the Pale, others threw in their lot with the native Irish, and became, in the well-known saying, *Hibernis ipsis Hiberniores* (see BURGH).

NORMANTON: see CARPENTARIA, GULF OF.

NORMANTON, an urban and colliery district of Yorkshire, England, 3 m. N.E. of Wakefield, on the L.M.S. and L.N.E. railways. Pop. (1921), 15,858. It is situated at an altitude of about 150 ft., in the Calder valley, 1½ m. from the right bank of the river, and is a railway junction for the line from Manchester to Leeds via Wakefield, and for the main line from the south via Chesterfield. A mound in the neighbourhood, called Haw hill, is believed to be a barrow. Traces remain of a moat surrounding the town. Altofts, a neighbouring parish, was the home of Sir Martin Frobisher in the 16th century.

NORNS, in Northern mythology, the female divinities of fate, like the Gr. Μοῖραι generally represented as three in number, and said to spin, or weave, the destiny of men. They dwell beside the "Spring of fate," beneath the "world-tree," Yggdrasil's ash, which they water from the spring. Sometimes the Norns are indistinguishable from the Valkyries (q.v.). They appear as prophetesses (*völur*) at the birth of children. The most famous story is contained in the *Tháttir af Nornagesti*. (See TEUTONIC PEOPLES.)

NORRIS, FRANK (1870-1902), American novelist, was born in Chicago (Ill.). March 5, 1870. Believing that America ignored her own national epic, he devoted himself to his uncompleted trilogy of the wheat. *The Octopus* (1901) shows with a striking use of symbolism the raising of the wheat in California and the hold of the railway upon the ranchmen; *The Pit* (1903) is a powerful portrayal of the lure of board of trade gambling; the author's early death prevented completion of the third volume, dealing with consumption in Europe. Reared in Chicago (Ill.), educated at the San Francisco high school, the University of California, and Harvard, he studied art in Paris and served in South Africa as war correspondent for the *San Francisco Chronicle*. In 1896-97 he was associate editor of the *San Francisco Wave*; and in 1898 he was war correspondent in Cuba for *McClure's Magazine*. He died Oct. 25, 1902.

Besides the wheat trilogy, Norris's most important works are: *A Deal in Wheat, and Other Stories of the New and Old West* (1903); *The Third Circle* (1909), another collection of tales; *The Responsibilities of the Novelist, and Other Literary Essays* (1903); *Moran of the Lady Letty* (1898), a tale of adventure off the California coast; *Blix* (1899), a love story; *McTeague* (1899), a story of the San Francisco slums; and *Vandover and the Brute* (1914), a repulsive study of degeneration, issued with an introduction by Charles G. Norris. For a bibliography see F. T. Cooper's *Some American Story Tellers* (1911).

NORRIS, GEORGE WILLIAM (1861-), American legislator, was born on a farm in Sandusky county, Ohio, on July 11, 1861. The death of his father and only brother while he was very young left the family in straitened circumstances, and Norris was required to work out among the farmers in the summer and attend school only in the winter. He afterwards taught school and studied law, and earned enough to finish his law course at Valparaiso university. He was admitted to the bar in 1883. In 1885 he moved to McCook, Neb., and began to practise. He was later elected prosecuting attorney of Furnas county, and in 1895 district judge of the 14th judicial district; re-elected in 1899, he was serving in this position when in 1902 he became

a U.S. representative. He was re-elected for five successive terms and in 1910 was the leader of the insurgent group which successfully held out for a reform of House rules, and thus put an end to the autocratic control of the speaker. He also led the fight against secret committee meetings. He was elected to the Senate in 1912, 1918 and 1924. He was one of the few who voted against the entrance of the United States into the World War, against the selective draft and anti-sedition acts, and he denounced the Versailles Treaty. He fought for the direct election of senators, and for presidential primaries. He was the author of a proposed amendment to abolish "lame-duck" Congresses. The Norris bill for retention of the Muscle Shoals power development by the Government, which passed the Senate in March 1928, marked the first indication of success in his six year fight to prevent Muscle Shoals from being acquired by private power interests. He was a leader in the demand for farm relief legislation, advocating a Government marketing corporation. He became the accepted leader of the independent group in Congress. Though nominally a Republican, party ties have rested lightly upon him, his dictum being that the people "ought to be independent of all parties." In 1926, outraged by Republican campaign expenditure in Pennsylvania, he entered that State to speak in favour of the Democratic nominee. In 1928 he supported Smith for the Presidency.

NORRIS, HENRY NORRIS or NORREYS, BARON (c. 1525-1601), belonged to an old Berkshire family, many members of which had held positions at the English court. His father, Henry Norris, was a grandson of Sir William Norris, who commanded the royal troops against Lambert Simnel at the battle of Stoke in 1487. Like his brother John (d. 1564), the elder Henry Norris obtained a post at the court of Henry VIII.; he gained the king's favour and was rewarded with many lucrative offices. He belonged to the party which favoured the elevation of Anne Boleyn; but in May 1536 he was arrested on the charge of intriguing with her, and though he was probably innocent of any serious offence, he was beheaded on May 17, 1536. His son Henry regained some of his father's lands and entered upon court life, being a member of parliament under Edward VI. During Mary's reign he was one of those who were entrusted with the custody of the princess Elizabeth, and when the princess became queen she amply repaid the kindness which Norris had shown to her when he was her guardian at Woodstock. In 1566 he was knighted and sent as ambassador to France, where he remained until 1570, and in 1572 he was created Baron Norris of Rycote. He died in June 1601.

The eldest of his six sons, Sir WILLIAM NORRIS, died in Ireland in Dec. 1579, leaving a son Francis (1579-1623), who succeeded to his grandfather's barony and also to the estates of his uncle Sir Edward Norris. In 1621 Francis was created earl of Berkshire. He left no sons and the earldom became extinct, but the barony descended to his daughter Elizabeth (d. 1645), the wife of Edward Wray (d. 1658). Their daughter Bridget (1627-57) married as his second wife Montagu Bertie, 2nd earl of Lindsey, and their son James Bertie (1654-99) became Baron Norris (or Norreys) in 1657, and was created earl of Abingdon in 1682. His descendants the Berties, earls of Abingdon, still hold this barony.

Sir EDWARD NORRIS (d. 1603), the 1st Lord Norris's third son, served with the English troops in the Netherlands from 1585 to 1588. He is chiefly remembered owing to his fierce quarrel with Philip, count of Hohenlohe (1550-1606), called Hollock by the English, in August 1586 at Gertruydenberg.

NORRIS, SIR JOHN (c. 1547-1597), English soldier, was the second son of Henry Norris, Baron Norris of Rycote, and gained his earliest military experience in the civil wars in France. In 1573 he went to Ulster with Walter Devereux, earl of Essex, winning fame by his conduct in the guerrilla wars against the Irish, and being responsible for the massacre on the island of Rathlin in July 1575. He was again in Ireland in 1584, but the greater part of these years was spent in service in the Netherlands. In 1588, when the Spanish Armada was expected, he was marshal of the camp at Tilbury; later in the same year he served the queen as ambassador to the Dutch states, and in 1589 he and Sir Francis

Drake led the fleet which ravaged the coasts of Spain and Portugal. In 1591, and again in 1593, he aided Henry IV. of France in his struggle with the League in Brittany; and in May 1595 he landed again in Ireland, where he was lord president of Munster. He was to assist the lord deputy, Sir William Russell, in subjugating Ulster. After fighting and negotiating with the O'Neills in Ulster, and warring in Connaught, he asked for his recall. This was not granted, but he was supplanted in his military command; and he retired to Munster and died at Mallow on July 3, 1597. His monument is in the church of Tattendon, Berkshire.

See J. L. Motley, *The United Netherlands*, vol. ii. (1904); and R. Bagwell, *Ireland under the Tudors*, vol. iii. (1890).

NORRIS, JOHN (1657–1711). English philosopher and divine, was born at Collingbourne-Kingston in Wiltshire. He was educated at Winchester and Exeter college, Oxford, being subsequently elected to a fellowship at All Souls'. His first original work was *An Idea of Happiness* (1683), in which, with Plato, he places the highest happiness or fruition of the soul in the contemplative love of God. He studied the works of Malebranche and of Descartes and his followers and opponents. Of English thinkers, More and Cudworth, the so-called Cambridge Platonists, had influenced him most; and in 1685 his study of their works led to a correspondence with More, published after his death by Norris as an appendix to his Platonically conceived essay on *The Theory and Regulation of Love* (1688). He also corresponded with Mrs. Astell (*q.v.*) and Lady Masham, the friend of Locke, to whom he addressed his *Reflections upon the Conduct of Human Life* (1689). In 1689 Norris was presented to the living of Newton St. Loe, in Somersetshire. In 1690 he published a volume of *Discourses upon the Beatitudes*, followed by three more volumes of *Practical Discourses* between 1690 and 1698. In an appendix to his *Discourses* he gave "Cursory Reflections" on Locke's *Essay on the Human Understanding* which anticipate many later criticisms of Locke's philosophy, though he was at one with Locke in dismissing the "grey-headed, venerable doctrine" of innate ideas. The last 20 years of Norris's life were spent at Bemerton, to the living of which he had been transferred in 1691. In 1691–1692 he was engaged in controversy with his old enemies the "Separatists," and with the Quakers, his Malebranchian theory of the divine illumination having been confounded by some with the Quaker doctrine of the light within. In 1697 he wrote *An Account of Reason and Faith*, one of the best of the many answers to Toland's *Christianity not Mysterious*. Reason, according to Norris, is nothing but the exact measure of truth, that is to say, divine reason, which differs from human reason only in degree, not in nature. In 1701 appeared his most important work, *An Essay towards the Theory of the Ideal or Intelligible World*. The first volume treats the intelligible world absolutely; the second, which appeared in 1704, considers it in relation to human understanding. It is a complete exposition of the system of Malebranche, in which Norris refutes the assertions of Locke and the sensualists. In 1708 Norris wrote *A Philosophical Discourse concerning the Natural Immortality of the Soul*, defending that doctrine against the assaults of Dodwell. He died at Bemerton, and a monument was erected to his memory in the church. He occupies a place in the succession of ecclesiastical and mystical thinkers of whom Coleridge is the last eminent example.

See Wood, *Athenae Oxonienses* (ed. Bliss), iv.; *Biographia Britannica*; Leslie Stephen in *Dictionary of National Biography*; J. Tulloch, *Rational Theology and Christian Philosophy in England in the 17th Century* (1874), who calls Norris "as striking and significant a figure in the history of English philosophy," as Berkeley, another idealist.

NORRIS, WILLIAM EDWARD (1847–1925). English novelist, was born on Nov. 18, 1847, the son of Sir W. Norris, chief justice of Ceylon. He was educated at Eton, and called to the bar at the Inner Temple in 1874. His first story, *Heaps of Money*, appeared in 1877, and was followed by *Mademoiselle de Mersac* (1880), *Matrimony* (1881), *No New Thing* (1883), *My Friend Jim* (1886), *The Despot's Lady* (1895), *Matthew Austin* (1895), *The Widower* (1898), *Pauline* (1908), *Not Guilty* (1910); *The Rt. Hon. Gentleman* (1913); *Barbara and Company* (1914); *The Triumphs of Sarah* (1920); *Sabine and Sabina* (1922); *Next of Kin* (1923) and *Trevalion* (1925). He died on Nov. 19, 1925.

NORRISTOWN, a borough of Pennsylvania, U.S.A., the county seat of Montgomery county; on the Schuylkill river, 17 m. N.W. of the centre of Philadelphia. It is served by the Pennsylvania and the Reading railways. Pop. 32,319 in 1920 (82% native white); estimated locally at over 39,000 in 1928. Across the river is the borough of Bridgeport (pop. 4,680 in 1920). Norristown is a residential suburb of Philadelphia, and its industries are textile machinery and stockings for children. The Eastern Pennsylvania State hospital for the insane is located here. Valley Forge (*q.v.*) is 7 m. S.W. of the city. The site of Norristown is part of a manorial estate purchased from William Penn in 1704 by Isaac Norris. The borough was incorporated in 1812.

NORRKÖPING, the fourth town of Sweden, in the district (*län*) of Östergötland, 113 m. S.W. of Stockholm by the Malmö railway. Pop. (1927), 60,400. A bull of Pope Lucius III. shows that Norrköping existed in 1185. In the 17th century, Duke John of Östergötland introduced German craftsmen into Norrköping. Under Charles XII. the town suffered not only from war but from pestilence, 2,700 of its inhabitants perishing in 1710–1711. After the Russian invasion of 1719 the population was only 2,600. Norrköping occupies both banks of the Motala, the wide and rapid emissary of lake Vetter. Fires in 1719, 1812, 1822 and 1826 have caused rebuilding on modern lines. The falls in the river afford motive power to the cloth and cotton mills (spinning and weaving)—the staple industries—and to factories for sugar, paper, lithography, tobacco and carpets, joinery works and breweries. There are also ship-building yards and docks. Fine granite is quarried at Grafversfors, 7½ m. north. The inlet of Bråvik affords excellent harbour facilities for vessels up to 18½ ft. draught near the quay, and safe anchorage up to 30 ft. in the Pampas roads, 6 m. from the town.

NORSE LANGUAGE. The Old Norwegian language (till the Reformation) was not, like the modern language, confined to Norway and the Färoe islands, but was for some time spoken in parts of Ireland and the north of Scotland, the Isle of Man, the Hebrides, Shetland and Orkney (where it continued to the end of the 18th century), and also in certain parts of western Sweden.

The runic inscriptions in Old Norse are few in number (about 150) and of trifling philological importance, since they belong almost wholly to the period between 1050 and 1350, and are consequently not much earlier than the earliest literature. The whole literature preserved is written in the Latin alphabet. The earliest manuscripts are not much later than the oldest Old Icelandic ones and are of the greatest interest. The masses of charters which occur throughout the whole middle age of Norway from the beginning of the 13th century give information, especially of dialect.

In Old Norwegian the most primitive forms occur in old poems from times as remote as the days of Þorbiörn Hornklofi (end of the 9th century). The language at this epoch differed very little from other Scandinavian dialects. From the 13th century, Norwegian, owing to geographical and political circumstances, is considerably influenced by the eastern Scandinavian languages. The tendency in Norwegian to reduce the use of the so-called *u-Umlaut* has already appeared. There appears another kind of vowel-assimilation, almost unknown to Icelandic, the vowel in terminations being in some degree influenced by the vowel of the preceding syllable. Thus, for instance, we find in some manuscripts that the vowels *e*, *o*, *ø*, and long *a*, *æ*, are followed in terminations by *e*, *o*; *i*, *u*, *y* and short *a*, *æ*, on the other hand, by *i*, *u*—as in *böner*, prayers, *konor*, women; but *tíðir*, times, *tungur*, tongues. The same fact occurs in certain Old Swedish manuscripts. When Norwegian had been united later with Sweden under one crown (1319) we meet pure Suecisms in the Norwegian literary language. In addition to this, the 14th century exhibits several differences from the old language: *ri*, *rn* are sometimes assimilated into *li*, *nn*—as *kall* (elder *karl*). man. *konn* (*korn*), corn, *prestanner* (*prestarnir*), the priests; *i* passes into *y* before *r*, *l*—as *hyrðir* (*hirðir*), shepherd, *lykyl* (*lykill*), key; final *-r* after a consonant is changed into *-ar*, *-er*, *-ir*, *-or*, *-ur* or *ær*, sometimes only *-a*, *-e*, *æ*—as *hester* (*hestir*), horse, *böker* (*bökr*), books, the names *polleifræ* (*þorleifr*), *Guðlaifæ* (*Guðleifr*). About the beginning of the 15th cen-

tury initial *kv* occurs for old *kv* (not, however, in pronouns, which take *kv* only in western Norway), as the local name *Quiteseið* (*kvitr*, white). During the 15th century, Norway being united with Denmark, and at intervals also with Sweden, a great many Danisms and a few Suecisms are imported into the language. Towards the end of the middle ages the Danish influence shows an immense increase, until at last Norwegian as a literary language is supplanted by Danish. Many Norse dialects developed in the 13th, 14th and 15th centuries. The language of western Norway resembles Icelandic, and the language of eastern Norway is still nearer to contemporary Old Swedish. The present dialectal division was in all essentials accomplished about the year 1600.

NORTH, BARONS. The English title of Lord North of Kirtling was created for Edward North (c. 1496–1564), son of Roger North, a London citizen, in 1554; he was a successful lawyer, clerk of the parliament (1531) and chancellor of the court of augmentations (1545). His second son was Sir Thomas North (q.v.), and he was succeeded as 2nd baron by his son Roger, a courtier and soldier of Queen Elizabeth's day, who married the daughter of Lord Chancellor Rich.

DUDLEY NORTH, 3rd Baron North (1581–1666), son of Sir John North and of Dorothy, daughter and heiress of Sir Valentine Dale, was born in 1581 and succeeded his grandfather, the 2nd Baron North, at the age of 19. He was educated at Cambridge, and married in 1599 Frances, daughter of Sir John Brockett of Brockett Hall, Hertfordshire. He travelled in Italy, took part in the campaign of 1602 in the Netherlands, and on his return became a conspicuous figure at court, excelling in athletic exercises as well as in poetry and music, and gaining the friendship of Prince Henry. In 1606, while returning from Eridge to London, he discovered the springs of Tunbridge Wells, which cured North himself of a complaint and quickly became famous. He also recommended the Epsom springs to the public. He supported and subscribed to the expedition to Guiana made by his brother Roger North (c. 1582–c. 1652) in 1619, and when Roger departed without leave Dudley was imprisoned for two days in the Fleet. In 1626 he attached himself to the party of Lord Saye and Sele in the Lords, who were in sympathy with the aims of the Commons; and when the civil war broke out he was on the side of the parliament. In 1641 he was a member of the Lords' committee on Religion, and served on the committee to consider Laud's attainder in 1644, finally voting for the ordinance in Jan. 1645. He was placed on the admiralty commission in 1645, and acted as lord lieutenant for Cambridgeshire. He was one of the small group of Lords who continued attendance in the House of Peers, and on Dec. 19, 1648, with three others, visited Fairfax, when they "cast down their honours at his Excellency's feet" and protested their desire not to retain any privileges prejudicial to the public interest. (Gardiner's *Civil War*, iv. 285.) He passed the rest of his life in retirement at Kirtling in Cambridgeshire, with his family, finding "employment with many airy entertainments as poetry, writing essays, building, making mottoes and inscriptions as well as in music." He wrote *A Forest of Varieties* (1645), a miscellany of essays and poems, another edition of which was published in 1659 under the title of *A Forest promiscuous of various Seasons' Productions*. He died on Jan. 16, 1666. North is described as "full of spirit and flame," of imperious temper but of well-balanced judgment, Lord Holland declaring that "he knew no man less swayed with passion and sooner carried with reason and justice." He left, besides one daughter, two sons, the elder of whom, Sir Dudley, succeeded him as 4th Baron North.

DUDLEY NORTH, 4th Baron North (1602–77), increased the family fortune by marrying the daughter of Sir Charles Montagu, brother of the 1st earl of Manchester. He was an accomplished man, of studious bent, and had 14 children, of whom the third son, Francis, became lord chancellor as Lord Guilford; the fourth was Sir Dudley North (q.v.), the economist; the fifth, John (1645–83), master of Trinity, Cambridge, and professor of Greek in the university; and the sixth, Roger (q.v.), the lawyer and historian.

The eldest son, Charles (d. 1691), was created Lord Grey

of Rolleston during his father's life, and succeeded his father as 5th Baron North; and on the death of his son, William, 6th Lord North, without issue, in 1734, the barony of North went to a cousin, Francis North, 3rd baron, afterwards 1st earl of Guilford. The title of Lord North is that by which the 2nd earl of Guilford, prime minister from 1770–82, is best known in history. (See GUILFORD, BARONS AND EARLS OF.)

George Augustus, 3rd earl of Guilford (d. 1802), left three daughters, and the barony of North fell into abeyance till 1841 when it vested in Susan, Baroness North (1797–1884), wife of John Sidney Doyle, who took the name of North; at her death her son William Henry John North (b. 1836) succeeded as 11th baron, the title now being separate from that of Guilford.

NORTH, SIR DUDLEY (1641–1691). English economist, was 4th son of Dudley, 4th Lord North, who published *Passages relating to the Long Parliament*, of which he had himself been a member. He was born on May 16, 1641, and in his youth was carried off by gipsies and recovered with some difficulty by his family. He engaged in foreign trade, especially with Turkey, and spent many years at Constantinople and Smyrna. During the Tory reaction under Charles II. he was one of the sheriffs forced on the city of London with an express view to securing verdicts for the Crown in state trials. He was knighted, and was appointed a commissioner of customs, afterwards of the treasury, and again of the customs. Under James II., "he took," says Roger North, "the place of manager for the Crown in all matters of revenue." After the Revolution he was called to account for his alleged unconstitutional proceedings in his office of sheriff. He died on Dec. 31, 1691.

His tract entitled *Discourses upon Trade, principally directed to the cases of the interest, coinage, clipping and increase of money*, was published anonymously in 1691, and was edited in 1856 by J. R. McCulloch in the *Select Collection of Early English Tracts on Commerce* printed by the Political Economy Club of London. In this emphatic assertion of the free-trade doctrine against the prevailing system of prohibitions, North shows that wealth may exist independently of gold or silver, its source being human industry, applied either to the cultivation of the soil or to manufactures. The export of money in the course of traffic, instead of diminishing, increases the national wealth, trade being only an exchange of superfluities. Nations are related to the world just in the same way as cities to the State or as families to the city. North emphasizes more than his predecessors the value of the home trade. With respect to the interest of capital, he maintains that it depends, like the price of any commodity, on the proportion of demand and supply, and that a low rate is a result of the relative increase of capital, and cannot be brought about by arbitrary regulations. In arguing the question of free trade, he urges that every advantage given to one interest over another is injurious to the public and that no trade is unprofitable to the public.

North, Locke and Petty are named by Wilhelm Roscher as the "great triumvirate" of English economists of the period.

NORTH, MARIANNE (1830–1890), English naturalist and flower-painter, was born at Hastings on Oct. 24, 1830, the eldest daughter of a Norfolk landowner, descended from Roger North (1653–1734). She trained as a vocalist under Madame Sainton Dolby, but her voice failed, and she then devoted herself to painting flowers. After the death of her parents she resolved to paint the flora of distant countries and with this objective she went to Canada, the United States and Jamaica, and spent a year in Brazil, where she did much of her work at a hut in the depths of a forest (1871–72). Later, she visited Tenerife, California, Japan, Borneo, Java, Ceylon, Australia, New Zealand, South Africa, the Seychelles and Chile; and the scientific accuracy with which she represented plant life gives her work a permanent value. In 1882, her gallery at Kew Gardens was opened. It contains her paintings. She died at Alderly in Gloucestershire on Aug. 30, 1890.

NORTH, ROGER (1653–1734), English lawyer and biographer, was the sixth son of the 4th Baron North. He acquired a good practice at the bar, being helped by his elder brother Francis, who became lord chancellor and was created Baron Guil-

ford (*q.v.*), and in 1684 he became solicitor-general. But the Revolution stopped his advancement, and he retired to his estate of Rougham in Norfolk, and increased his fortune by marrying the daughter of Sir Robert Gayer. He collected books, and was constantly occupied in writing. He is best known for his *Lives of the Norths*, published after his death, together with his own autobiography (see the edition in Bohn's *Standard Library*, 1890, by Jessopp), a classic authority for the period. He died at Rougham on March 1, 1734.

He is to be distinguished from Roger North (1585-1652), brother of the 3rd baron, one of the captains who sailed with Raleigh in 1617, and who projected the plantation of Guiana.

NORTH, SIR THOMAS (1535?-1601?), English translator of *Plutarch*, second son of the 1st Baron North, was born about 1535. He is supposed to have been a student of Peterhouse, Cambridge, and was entered at Lincoln's Inn in 1557. In 1574 he accompanied his brother, Lord North, on a visit to the French court. He served as captain in the year of the Armada, and was knighted about three years later. He was a justice of the peace for Cambridge in 1592 and again in 1597, and he received a pension (£40 a year) from the queen in 1601. He translated, in 1557, Guevara's *Reloj de Principes* (commonly known as *Libro Aureo*) (see GUEVARA) under the title of *Diall of Princes*. The English of this work is one of the earliest specimens of the ornate, copious and pointed style for which educated young Englishmen had acquired a taste in their continental travels and studies. With its mannerisms and constant use of antithesis, it set the fashion which was to culminate in Lyly's *Euphues*. His next work was *The Morall Philosophie of Domi* (1570), a translation of an Italian collection of eastern fables. The first edition of his translation of *Plutarch*, from the French of Jacques Amyot, appeared in 1579. The first edition was dedicated to Queen Elizabeth, and was followed by other editions in 1595 and 1603, containing in each case fresh *Lives*. The influence of North's vigorous English on contemporary writers was very great, and some critics have called him the first master of English prose. The book formed the source from which Shakespeare drew the materials for his *Julius Caesar*, *Coriolanus* and *Antony and Cleopatra*. It is in the last-named play that he follows the *Lives* most closely, whole speeches being taken direct from North.

See *Plutarch's Lives of the Noble Grecians and Romans: English ed. by Sir T. North* (in Tudor Translations, 1895); *Shakespeare's Plutarch* (a selection ed. C. F. T. Brooke, 1909); *The Diall of Princes* (reprinted 1921); F. Bushby, *Three Men of Tudor Times* (1911).

NORTH, THE, originally those of the English Colonies in America north of the Mason and Dixon line (*q.v.*), as distinguished from those south. They were New Hampshire, Massachusetts, Rhode Island, Connecticut, New York, New Jersey and Pennsylvania. With the extension of settlements across the Alleghenies, the Ohio river was considered as a continuation of the Mason and Dixon line to the Mississippi river. Missouri, west of the Mississippi, was before the Civil War, considered part of the South because it was a slave-holding State, but after the Civil War it became a part of the North in its political and economic life. West of Missouri the boundary between the two sections followed the southern boundary of Kansas (37° N. lat.) to the Great Plains. Beyond were the Western States which, because they supported the North, were usually considered part of it during the great struggle over slavery. The characteristic Northern life and settlement was broken, however, by the Great Plains which may, therefore, be considered to form the western boundary of the section.

The division between the North and the South was in no slight degree a natural one. In the North land and climate made small farms with diversified crops the only profitable type of agriculture. In the older sections the limited supply of farm land and the abundant amount of water-power stimulated manufacturing and the growth of town life. In the South, large plantations growing only cotton, or only tobacco, and dependent upon slave labour came into existence. As these economic systems with their attendant social differences grew in power and clashed in conflict over the virgin lands of the West, an intense struggle developed for supremacy, a struggle fought first, but vainly, in the halls of

Congress, and later on the battlefields of the Civil War. The North through its victory gained undisputed political, economic and cultural supremacy. Politically, the North has always been the stronghold of the Republican Party which has fostered its industrial interests.

NORTH ADAMS, a city of Massachusetts, on the Hoosac river and at the west end of the Hoosac tunnel, served by the Boston and Albany and the Boston and Maine railways. Pop. (1920) 22,282 (23% foreign-born white); 1928 local estimate, over 25,000. The city has a beautiful situation, 700 ft. above sea-level, in the foot-hills of the Berkshires, at the west end of the Mohawk trail. Within its limits is a natural bridge 50 to 60 ft. high, across Hudson Brook. It is the seat of a State normal school (1897) and has extensive manufactures (chiefly cotton print, woollen goods, cotton cloth, boots and shoes, and machinery) with an output in 1925 valued at \$50,000,000. In the western part of the city are the ruins of Ft. Massachusetts, built in 1745 by the Massachusetts Bay Colony as a frontier defence, and captured in 1746 by French and Indians under the Chevalier de Vaudreuil. North Adams was set off from Adams and incorporated as a town in 1878, and in 1895 it was chartered as a city.

NORTHALLERTON, an urban district, market town and administrative capital of the North Riding of Yorkshire, England, 30 m. N.N.W. of York by the L.N.E. railway, on which it is an important junction. Pop. (1921) 4,794. It is situated on a slight eminence at the foot of the Cleveland and Hambleton Hills, 3 m. from the bank of the Swale. It thus avoids the flood land of the Vale of York. Here the western scarp of the Wolds causes the Vale to narrow to a width of 10 m., forming the Northallerton Gate.

Northallerton (Alvetune, Allerton) is believed to have been a Roman station, and the importance of the Gate is marked by two Roman roads, one running north from Catterick, the other from York. It was probably later a Saxon "burgh," and a Danish settlement, but nothing is known with certainty about it before the account given in the Domesday Survey, which shows that the Normans had destroyed the manor so utterly that it was still waste in 1086. In mediaeval times, the Gate was an obvious way south into England for the Scottish army. The Battle of the Standard was fought near the town in 1138 and the castle was destroyed in 1174. In 1317, the town was burnt by the Scots under Robert Bruce. Soon after his accession, William Rufus gave Northallerton to the Bishop of Durham, whose successors continued to hold it until it was taken over by the ecclesiastical commissioners in 1865. There are now no traces of the fortified palace of the bishops. A priory was founded here in 1341, and a White Friars monastery in 1354, and all trace of these also has been lost. The Mount Grace priory, a Carthusian foundation of 1397, remains.

According to an inquisition taken in 1333, the town, markets and fairs were held by the burgesses who were governed by two reeves and the bishop's bailiff. This form of government continued until 1851, when a local board was formed, and this was superseded by an urban district council in 1894. As a borough by prescription, Northallerton returned two members to the parliament of 1298, but it was not represented again until 1640 when its earlier privileges were restored. The Municipal Reform Act of 1832 reduced the number of members to one, and in 1885 representation of the town was merged in that of the district. It is now in the Richmond parliamentary division.

The town has a considerable trade in dairy farming and has held a weekly market since 1205. A fair held on St. Bartholomew's day was famous for cattle in the 16th century, but it is no longer held. Northallerton is to-day the railway focus of the Gate. It now has an important motor-engineering industry.

See C. J. D. Ingledeu, *History and Antiquities of Northallerton in the County of York* (1858); J. L. Saywell, *History and Annals of Northallerton* (1885); *Victoria County History, Yorkshire*.

NORTH AMERICA. The continent of North America has a mean altitude of about 2,000 ft., and an area of some 8,000,000 sq.m., 16% of the earth's land area and 4% of the earth's entire surface. Certain correspondences of its geological structure and history with those of the greater part of Europe and Asia, sym-

metrically disposed, right and left, with respect to the Atlantic, support the view that Eurasia is a single continent: furthermore they controvert the idea that the New World of discovery is an old world geologically; and that the Old World of history is geologically new. Both worlds are in part old, in part new; both share structures and changes of similar dates from the most ancient to the most modern periods.

PHYSICAL FEATURES

The Laurentian Region.—The general structural features of North America are as follows: the extensive area of ancient crystalline rocks, stretching from Labrador past Hudson bay and thence north-westward to the Arctic ocean, is of disordered structure; the surface now seen must have been originally buried at a considerable depth beneath a higher and mountainous surface; but that higher surface was reduced to low relief at a remote period. The Laurentian part of this great region has been described as the first emerged land area of North America, around which many later additions on the south and west built up the present continent; but a more modern interpretation shows that the worn-down Laurentian region is only part of a much larger land mass which in pre-Palaeozoic time extended more or less continuously as far as Texas and parts of the Rocky mountain region, and on which marine deposits were unconformably deposited as the land mass was progressively submerged beneath the Palaeozoic ocean. Hence the Laurentian region differs from other parts of North America more in having escaped later deformation than in being of earlier origin. In Pleistocene time, the Laurentian region became the centre from which ice sheets spread out on all sides. As a result the weathered soils were swept away, together with an unknown measure of unweathered rock, leaving scattered boulders and gravelly drift upon a rugged upland without mountains (except in Labrador), but diversified by innumerable knobs and hollows, and here and there covered by clay belts that are arable though of severe winter climate. The drainage of the region, which in pre-glacial times was probably accomplished by well-ordered rivers, was thus thrown into great disorder; large and small lakes abound, and some of the lakes have two outlets; the streams are repeatedly interrupted by rapids and not infrequently split into two channels, enclosing islands many miles in length. The region remains a forest wilderness, except at mining centres (several of which have produced large quantities of nickel, silver and gold), pulp mills and on the sparsely settled clay belts.

The Appalachian Area.—This is a hilly and mountainous belt, stretching from Newfoundland to Alabama, with a western branch in Arkansas. It seems to have belonged in the earliest times to the great pre-Palaeozoic land mass, but it must be set aside from the undisturbed Laurentian region because of repeated movements of depression, deformation and elevation that it has suffered, generally along a northeast-southwest trend, causing alternations of heavy deposition and almost equally heavy degradation. These movements took place with generally decreasing intensity, through nearly the whole stretch of geological time covered by the fossiliferous record. The Appalachian mountains of today were formerly regarded as unconsumed residuals of greater mountains formed at the close of the Palaeozoic period; but it is now generally agreed that Mesozoic erosion reduced most of that ancient range to a lowland of moderate or small relief, leaving only isolated groups of subdued mountains in the areas of the most resistant rocks; and that the altitude and form of the mountains to-day, as well as of a belt of horizontal strata on the west, now known as the Allegheny plateau, are largely the result of Tertiary elevation and dissection of the previously worn-down mass; the additional height thus given to the subdued mountain groups made them the loftiest parts of the range to-day, as in the White mountains of New Hampshire (Mt. Washington, 6,295 ft.) and the Black mountains of North Carolina (Mt. Mitchell, 6,711 ft.). The Ozark plateau of Missouri and the Ouachita mountains of Arkansas and farther west are related to each other in much the same way as the Allegheny plateau and the middle and southern Appalachians. Numerous coal seams occupy discontinuous basins in the Appalachians from Nova Scotia to Pennsylvania and in

the Allegheny plateau from Pennsylvania to Alabama, and in the extension of the same strata across the Ohio basin. The eastern coast of the continent has a rocky and irregular shore line from Greenland and Labrador to Massachusetts, with numerous submerged valleys forming bays and as many uplands and ridges outstanding in promontories and islands; this being the result of an increasing measure of depression to the north, where an archipelago now replaces what was probably once a corner of the continent. A coastal plain of gently inclined and imperfectly consolidated strata, which still borders the Gulf and part of the Atlantic coast of the United States formerly extended north-east, probably at least as far as Nova Scotia; the same depression that has brought the ocean upon the older rocks from Massachusetts northward, has diminished the breadth of the coastal plain and embayed its shore line from North Carolina to the mouth of the Hudson, and has submerged it from the Hudson mouth, north-eastward.

The Western Highlands.—The great complex of mountains in the Western highlands, sometimes styled the Cordilleras of North America (of which the Rocky mountains are eastern members in the United States and Canada), differs from the Eastern highlands in having suffered strong deformation in late geological periods. On the other hand, the transition from Palaeozoic to Mesozoic times, when mountain-making disturbances were so general in western Europe and eastern North America that the older geologists thought them to be of world-wide extent, was here generally accomplished in relative quiet, so that in certain districts a conformable succession of stratified formations was accumulated in great thickness from Cambrian to late Mesozoic or early Tertiary time. Further, the Carboniferous period was marked by the deposition of marine limestones in the Cordilleran region. In contrast to the long quiescent Atlantic coast, the Pacific coast of North America is bordered for a good part of its length by mountains of late origin.

Volcanoes of commanding height here and there dominate the Western plateaux and mountains. Orizaba (18,240 ft.), Popocatepetl and their neighbours crown the southern portion of the Cordilleran system in Mexico; Mt. San Francisco rises over the desert plateau of Arizona and bears snow and Arctic plants; Shasta has small glaciers in northern California; Rainier, bearing large glaciers, surmounts the Cascade range in Washington; Wrangell is a lofty volcanic mass in Alaska. Vast lava floods have been poured out at various periods; those of the Snake and Columbia river basins in Washington, Oregon and Idaho are the most extensive. Similar lava-flows in British Columbia have been broadly uplifted and are now deeply dissected by Frazer river and its branches, leaving only disconnected highland patches.

As in all regions of great altitude, the erosion of valleys has progressed on a magnificent scale in the Cordilleran region. The plateaux of northern Arizona are traversed by the canyons of the Colorado river and its branches, at places over a mile in depth; yet upon the plateaux themselves, long and ragged cliffs of recession attest a vastly greater erosion before the uplift of the plateaux than is demanded by the canyons after uplift. Along the Pacific coast, as well as in the higher ranges of the northwest interior, intense glacial erosion during the Glacial period excavated huge cirques at the valley heads and deep troughs along the valley courses; on the coast these troughs are now occupied by sea water as fjords. Fitting complements to the deep erosion of the mountain masses are found in the great accumulations of mountain waste in various intermont and piedmont basins, of which the so-called valley of California is the finest example. Similar basin deposits of Tertiary date abound in the Cordilleran region.

Central Plains.—Between the lower Eastern highlands and the higher Western highlands lies a great extension of medial plains, stretching in moderate altitude from the Arctic ocean to the Gulf of Mexico and having at their mid-length a breadth of 1,500 miles. They are composed throughout of nearly horizontal strata and mark a region long exempt from deformation. The eastern plains, best represented in the Ohio valley, are underlain by Palaeozoic strata, already mentioned as having been laid down on the subsiding Archæan continent; the western plains are com-

posed of Mesozoic and Tertiary strata. Both east and west large areas of the plains do not owe their present evenness to the preservation of their originally smooth surface, but to the degradation of that surface from the considerable altitude of its first uplift to low relief. The degraded surface has, however, been smoothed by veneers of till plains in the Ohio and upper Mississippi valleys, and by the addition of extensive piedmont detrital deposits in the central-western plains.

The Cordilleras of North and South America are not only far out of line with each other, but are separated by some 1,200 m. in Central America, where, in association with the West Indies, an Antillean system of late geological deformation with east and west trends is believed to prevail, with abundant volcanic additions on the Pacific border and along the curved range of the Lesser Antilles, while in an intermediate space the calcareous lowlands of Yucatan resemble those of Florida in being the emerged parts of a larger area, much of which is still below the waters of the Gulf of Mexico. The warm waters that bathe the West Indies permit the growth of coral reefs in the Caribbean; the Bahamas are the slightly overtopping parts of broad plateaus of calcareous deposits, of which the greater area constitutes extensive shallow banks which descend steeply to great depths.

Rivers.—The successive crustal movements by which North America has been developed have determined the growth of several great river systems. The broad upheavals which developed the medial plains had the effect of engrafting many rivers from the Eastern and Western highlands upon trunks of unusual dimensions. Thus the Mississippi system, some of whose eastern tributaries probably date from early Mesozoic times, received great reinforcement by the addition of many long western branches in late Tertiary time, roughly contemporaneous with the uplift of the southern coastal plain, by which the lower trunk of the river was extended from its mid-length into the gulf. The present headwaters of that river-trunk to which the name of Mississippi has been rather arbitrarily applied are of very modern date, as they are consequent upon the abundant glacial deposits of northern Minnesota; and relatively modern courses appear to have been taken by the earlier-born Ohio and Missouri around the margin of invading Canadian ice sheets, which displaced them from earlier courses. The evolution of the Mackenzie resembles that of the Mississippi in a general way, but it has presumably been much affected by Glacial erosion and deposition, in consequence of which it, like the St. Lawrence, has many large lakes in its course. The régime of this great north-flowing river is strikingly unlike that of its south-flowing analogue on account of its course being from a warmer to a colder climate; hence while Mississippi floods have a free southward discharge, the floods of the Mackenzie have an obstructed northward discharge due to ice dams. Indeed, but for the complications that appear to be related to the outspread of Laurentian ice sheets, the areas drained by the Nelson and the St. Lawrence, now flowing to Hudson bay and St. Lawrence gulf, would be discharged by the Mackenzie and Mississippi. For a time, during the presence of the ice sheets that simpler system was realized for the Mississippi, when it carried to the Gulf of Mexico much drainage now received by the St. Lawrence and Nelson; the flood plain of its lower trunk was probably given its great breadth at that time. Lake Superior is peculiar in apparently owing its great depth to a somewhat pronounced displacement of its basin floor, in addition to whatever deepening it gained by glacial erosion.

The chief rivers that discharge to the Pacific rank below those that discharge to the Atlantic; but the Yukon, flowing from farther Canada and inner Alaska is one of the great rivers of the world. The Columbia, of hardly inferior rank, drains a large area of the Cordilleran system in Canada and the United States; it is peculiar in having one of its head branches rise at the eastern base of the Rocky mountains in Montana, so that its waters flow westward through all the Cordilleran ranges of its latitude. The Colorado discharges a muddy current into the Gulf of California.

Climate.—The climate of North America exhibits modifications of general conditions resulting from the globular form and eastward rotation of the earth. In January a mean temperature

of zero or less invades the region north-west of Hudson bay, which thus resembles north-eastern Asia in departing greatly from the more temperate mean prevailing in similar latitudes on the northern oceans. In July the great middle area of the continent becomes warmer than the oceans on the east and west, having a mean temperature above 80° and in part above 90°. Consequently the annual range between the means of January and July exceeds 40° for a large part of the continent, and exceeds 70° for much of the northern lands; the range of extreme temperatures is much greater. On corresponding northern oceanic areas, the temperature range is little more than 20°; and in the Southern Hemisphere it is probably less than 10°.

The several members of the terrestrial wind system, including therein the trades of a broadened torrid zone, the prevailing and stormy westerlies of middle latitudes, and the irregular winds of the polar region, are well exemplified over North America; but they are better seen in the drift of clouds than in the movements of the surface winds. In consequence of the dominance of westerly winds, a great stretch of the Pacific coast, even as far north as Alaska, has a small annual temperature range (generally less than 20°); while a range appropriate to continental interiors is experienced over most of the eastern coast of the continent in temperate latitudes; hence the extraordinary unlikeness between the climates of western Europe and eastern North America, where habitable Great Britain faces almost uninhabitable Labrador. The distribution of rainfall is likewise largely controlled by the general wind system. The West Indies, especially the mountainous islands, receive abundant precipitation from the passing trade winds. In Mexico and Guatemala the eastern slopes are for the most part better watered by the same winds (maximum, over 100 in.) than the western slopes. Farther north the reverse holds true; the Pacific coast north of latitude 40° has an abundant rainfall (maximum over 100 in.), and its mountains are clothed with dense forests; but there are large areas of deficient rainfall (less than 20 in.) in the interior where the intermont and piedmont plains of the Cordilleras in middle latitudes are dry and treeless. Regions of heavy snowfall are chiefly in the far north-western Cordilleras; over the northern interior and in Greenland the snowfall is less heavy, but the persistence of winter cold preserves much of the small amount that is received.

The extension of the continent across the belts of the wind system tends to turn branches from the westerlies to the trades along the mountainous Pacific coast, and from the trades to the westerlies over the open interior and on the Atlantic coast; it is partly because of this deflection of general circulation up the Mississippi valley, aided by cyclonic indrafts, that the eastern interior of the continent receives, especially in summer, so beneficial a rainfall (over 40 in.) over its forests and prairies. In winter when inflowing winds from the south are replaced by outflowing winds from the north, little rain or snow would fall there, but for the repeated passage of cyclonic storms across the continent, by which the outflow appropriate to the cold season is temporarily reversed. The free play of cyclonic winds north and south over the great medial plains permits indrafts from torrid and frigid sources, often succeeding each other rapidly, and producing, especially in winter, great and rapid changes of temperature. Similar but less extreme contrasts are produced by winds drawn in on the eastern coast from over the warm waters of the Gulf stream and from the cold waters of the Labrador current. The equatorward flow of the branching winds along the Pacific coast gives them a drying power; hence the arid region of the United States and north-western Mexico broadens toward the Pacific, and is strongly unlike the rainy and heavily forested coastal slopes of the north-western United States and western Canada. The belt of passage between the dry and the rainy areas migrates southward in the winter, carrying wet weather with it as the stormy westerly winds reach lower latitudes; a reverse migration takes place in summer, carrying fair weather northward. The extremity of the peninsula of Lower California, in Mexico, receives a small measure of convectional summer rains, as does south-eastern Florida.

Fauna and Flora.—The fauna of North America (Nearctic) is more closely related to that of Europe-Asia (Palearctic) than

to that of any other zoogeographical province; the two areas are united by many writers in one province (Holarctic). The reindeer (caribou), beaver and polar bear are found in both; the moose, wapiti, bison and grizzly bear of North America are closely related to the elk, red deer or stag, bison, and brown bear of Eurasia; and the following groups are well represented in both provinces: cats, lynxes, weasels, bears, wolves, foxes, seals, hares, squirrels, marmots, lemming, sheep and deer. The following forms are characteristic of North America: (rodents) pouched rats or gophers, musk-rat, prairie dog, Canadian porcupine; (carnivora) raccoon and skunk; (ungulates) musk ox, big-horn, Rocky mountain goat, prong-horn; (marsupial) opossum. Among birds, there is a close resemblance to those of Eurasia, with some admixture of South American forms, such as humming birds. Characteristic forms are the Baltimore oriole, bobolink, cowbird, flycatchers, wood-warblers, Californian quail, tree grouse, sage grouse, wild turkey and turkey buzzard. Turtles are especially numerous; salamanders are varied and large; rattlesnakes are among the reptiles.

The floral area of North America, defined by form and climate, may be divided into five belts; the eastern forested area, the western forested area, the interior unforested area, the northern barren lands and the torrid coasts. The eastern forested area extends from the Laurentian highland in Canada southward to the Gulf and Atlantic coast east of the Mississippi; in the north and southward along the mountains the trees are largely conifers with a mixture of birches, poplars and maples; southward, especially in the interior and at low levels, the conifers almost disappear and oaks, hickories, plane-trees, tulip-trees, walnuts and other valuable deciduous trees are in abundance; the long-leaf pine characterizes the low coastal margin. The western forested area begins in the Rocky mountains and extends to the Pacific, but does not descend below the lower timber line into the dry intermont basins of middle latitudes; northward in Canada, the forest is continuous from the upper timber line down into the valleys; it attains a luxurious and dense development along the rainy coast, where the redwood (*Sequoia*) of northern California and Oregon reaches a height of from 300 to 400 feet. The unforested area of the interior includes two dissimilar regions. On the east are the fertile prairies, spreading between the middle Ohio and the upper Great Lakes and extending beyond the Mississippi; here the native grasses and herbaceous vegetation are now largely replaced by agricultural crops. On the west under a drier climate vegetation is more scanty; but far north a wooded belt connects the eastern and western forests across the medial plains. Aridity and barrenness increase south-westward into California and southward into Mexico; on this broad desert few trees are found, although piñons grow on cliffs and ledges and cottonwoods are found along watercourses; and the mountains that rise above the desert carry forests. The desert vegetation consists of cactus, agaves, sage-brush (*Artemisia*) and other dry-climate plants in large variety. In the far north are the "barren lands," with their permanently frozen subsoil: the growing season here is short and trees cannot develop, although birches, poplars, willows and some other genera which attain good size southward are here present as dwarfed shrubs. The torrid coasts support a tropical vegetation; it is somewhat developed in Florida and becomes dominant in Mexico and Central America.

(W. M. D.)

POPULATION

In the accompanying table are given the best available data regarding the numbers of people in the major political divisions of North America and the islands in the Caribbean sea generally classed as belonging to this continent. Unfortunately, there are no actual census counts available for some of the smaller countries. The data in column B tell whether the figures given in column C are census figures or estimates and the date on which they were presumably gathered. The data in column D are estimates as the column heading indicates and were made by the author on the basis of the available information.

In the case of Mexico, because of the unsettled condition of affairs during the period 1910-20, which apparently resulted in a loss of population and because there is no means of telling

whether the quieter period since about 1920 has brought about an increase, or if it has, whether this increase has largely migrated to the United States, no estimate of reasonable accuracy seemed possible.

In column E is given the density per square mile of the population in the different countries. It will be seen from these data that some of the smaller islands among the West Indies are very densely populated, indeed they are among the most densely peopled parts of the world. Jamaica, Porto Rico and Haiti are also quite thickly settled, their density being comparable to that of France.

In column F are given the populations of the same areas in 1881 or thereabouts—40 years earlier. It will be seen that the population of the continent has almost doubled during this time.

Urban and Rural.—In Canada 49.52% of the population was urban in 1921 and 50.48% rural. In this case rural includes all unincorporated towns and the open country, and consequently is not exactly comparable with the same classification in the United States. In the latter country all places having a population of 2,500 or more are considered urban and constituted 51.4% of the total population in 1920 and the rural population was, therefore, only 48.6%. In Mexico, Central America and the West Indies similar classifications are not made, but a large part of the people in this area live in rural territory. Commerce and manufacturing are not highly developed in any of these countries, hence they cannot support very large city populations. Mexico City and Havana are the only cities which could be called large. This part of North America is essentially agricultural.

Racial Composition.—The base of the population in Mexico and Central America is Indian. In Mexico, for example, the census of 1921 reported (in round numbers) 1,400,000 whites, 4,200,000 Indians and 8,500,000 of mixed blood (almost wholly white and Indian). Thus, less than 10% of the population is considered white, locally, and the percentage of pure white stock is certainly much smaller. What is true of Mexico is true also of the Central American republics. Furthermore in these, the Indians and mixed stocks are being still further mixed by a considerable immigration of West Indian negroes.

In the West Indies there are great differences between islands, but the predominant stock in the tropic isles is negro, very generally mixed with white stock and in some cases with Indian stock. The amount of pure white stock is nowhere very large. This statement holds in spite of the fact that Porto Rico reports about 72% of its 1,299,000 inhabitants as white.

In the United States certain racial lines are closely drawn. Of the total population in 1920 there were 10,463,131 or 9.9% classed as negro, 244,437 or 0.2% as Indian and 182,137 or 0.2% are other coloured. The white stock constituted 89.7% of the total. In Canada the number of negroes was only 18,291 (1921) or 0.21%, the Indians constituted only 1.26%, and the Asiatic people only 0.75%. The important distinction in Canada, however, is that between British and French, the former constituting 55.4% of the total population in 1921, while the latter constituted 27.9%. Thus Canada, unlike most other countries in North America, has no real "colour problem" but only a "language problem."

The total population in North America in 1920 was approximately 143,000,000, or about one-third that of Europe. This population was scattered over an area 2.25 times as great so that its density was only about one-sixth that of Europe. (W. S. T.)

ETHNOLOGY

The Indians of North, as of South, America are believed to have had their origin in the eastern hemisphere. In the New World there are no unquestioned fossils of human ancestors or extinct human races, such as Europe, Africa, Asia and Oceania contain. Then, many regions of the Old World are studded with sites containing implements and refuse of pure Palaeolithic type, whose geological formation and associated animal bones leave no doubt that they were occupied during the Pleistocene or glacial era; but in America there are no such sites, implements of Palaeolithic type being normally found in association with Neolithic ones.

There is no reason to believe that the entry of man into

**Includes Virgin islands.

America occurred as a single migration which was discontinued and never resumed. If one body of immigrants was able to find the way, it is almost certain that others would find it. The great speech diversification of America may have begun while the original speakers were still in the Old World.

THE PEOPLING

It is practically certain that the peopling took place from Siberia via Bering Strait, other land bridges to America being geologically too ancient to have served man. Bering Strait is shallow, frozen over part of each year, less than 50 miles wide, with the Diomed islands near the middle. While probably never an insuperable obstacle even to primitive peoples, it never has been and is not now an easy means of communication; and the lands on both sides of it are inhospitable and capable of sustaining only a thin population. The Strait thus served much like a kinked tube. Man managed to filter through, and culture elements succeeded in being transmitted, but the flow of both was impeded.

There is no evidence that until the Russian occupation any advanced people ever occupied north-eastern Asia. Consequently, whatever relatively late accessions of inventions or other cultural materials reached the American Indians, were of a type normally occurring among peoples of a relatively low level. Both in America and Asia the higher attainments of civilization occur in latitudes not far from or below the Tropic of Cancer.

That the intercontinental connections occurred as just outlined, is strongly suggested by recent ethnic conditions about Bering

Strait. The Eskimos on both sides of the strait are almost identical in physique, speech and customs; and farther back live Palaeo-Asiatic tribes (Chukchee, Koryak, Yukaghir) and American tribes (Dene, Tlingit, Haida) which resemble each other so conspicuously that some authorities have included the Palaeo-Asiatic ones with the Indians.

Race.—It follows that the racial origin of the American Indian has to be sought in Asia. The findings of anthropometry bear out the inference. The Indian belongs obviously to the Mongoloid division of the human species. He is brown skinned, with straight, stiff, black head hair, a minimum of beard and body hair, a definitely broad face (in popular parlance, high cheek bones), and moderate prognathism. These traits are constant among Indians, as among East Asiatics. Minor peculiarities, such as shovel-shaped incisor teeth, and bluish pigment spots in the sacral region during infancy, occur equally among the two populations.

The relations of the American Indian are, however, to the Mongoloid stock as a whole rather than to any specific Mongolian people. They are probably closest to the East Siberians.

Although often called "red," the American Indians are so only when they paint themselves. Their general colour is a brown, little if any darker than that of the Japanese. The tallest people are found in the centre of the continent in the Mississippi valley, and for some distance north and east. Along the Pacific coast and in Mexico, body heights are less. The Aztecs and Mayas were short peoples. Head form is about as variable as in the Old World. In general, the cranial index is 79 or above (cephalic

index 81+), except in six areas where it is less (longer heads): 1, the Eskimos of the Arctic coast; 2, 3, 4, in the east, from Cape Hatteras to St. Lawrence river; from the St. Lawrence north of the Great Lakes almost to the Rockies; an irregular tract in the Ohio and middle Mississippi valleys; 5, 6, on or near the Pacific coast, two intermittent tracts or chains of separated groups, between northern California and the tip of Baja California; from southern Arizona to central Mexico. In South America the long heads are almost all found in the eastern half of the continent, in or adjacent to Brazil.

The Eskimos (*q.v.*) are a well-marked sub-race. They are short, thick set, unusually long headed and broad faced, powerful jawed, narrow nosed, and with some tendency to the Mongolian eye. The remainder of the American race is difficult to sub-classify satisfactorily. Hrdlička distinguishes three types, of which he considers all existing populations in North and South America to be either representatives or mixtures. These are: 1, tall and broad headed (Athabaskan); 2, long headed, mostly tall; 3, broad headed, stature moderate to short. The more advanced peoples from Mexico to Peru are assigned to this third type.

There are some interesting but as yet insufficient indications of Australian or Melanesian Negroid influence on the physique of the American Indians of certain localities. The very long and low skulls of the south end of Baja California may represent a colony or infusion of such immigrants. Similar conjectures have been advanced about the long headed peoples of the Atlantic sides of both North and South America.

Language.—The outstanding characteristic of native American speech is its diversity. According to the usual reckoning there are more stocks of languages in either North or South America than in the entire eastern hemisphere—about 75 on each continent. Recent researches have moved in the direction of uncovering remote similarities between some of these stocks, thereby reducing their number. There is little indication of borrowing between languages, except in South America.

The older view that American languages are overwhelmingly agglutinating, incorporating or polysynthetic, can no longer be maintained. There are languages as genuinely inflectional (Penutian) and isolating (Otomi, Zapotec) as in the Old World. It is, however, true that the Indian languages tend to describe concretely and visually. Elements expressing the instrument or manner of action, the shape or position, and space relations, although by no means universal, are frequently well developed in the grammatical structure. It is also true that many of the idioms do not shrink from piling up structural elements into long words.

The most important linguistic stocks north of Costa Rica, in point of number of speakers or territory, are Eskimo, Athabaskan, Algonkin, Iroquoian, Siouan, Muskogi, Caddoan, Uto-Aztecan, Salish, Sahaptin, Penutian, Hokan, Tarascan, Otomi, Totonac, Zapotecan, Mixe-Zoque, Maya, all of which are separately described. Of secondary rank, and also treated separately, are Tlingit and Haida (with Athabaskan = Na-Dene?), Tsimshian, Wakashan (Kwakiutl and Nutka), Chinook, Kootenay, three Pueblo stocks (Tanoan, Keres, Zuñi), Kiowa (with Tanoan?), Tonkawa, Natchez (probably with Muskogi), Yuchi, Beothuk. The remaining small stocks are in Washington, Chimakum; in Oregon, Wailatpu and Lutuami (with Sahaptin?); Kalapuya; Yakonan; Kus and Takelma (Penutian?); in California, Yurok and Wiyot (Algonkin?), and Yuki; in Texas, Coahuiltecan and Karankawa (Hokan?); in Louisiana, Tunica, Chitimacha, Atakapa (probably related); in Florida, Timucua, Calusa, perhaps Arawak and Carib colonies; in north-eastern Mexico, Tamaulipan, Xanambre, Olive, Lagunero; in Baja California, Waicuri and Pericu (perhaps distinct); in Guerrero and Nicaragua, Subtiaba; in Oaxaca, Huave (Mixe-Zoque?); in Chiapas and Nicaragua, Chiapanec (Chorotec, Chinantec); and, in Honduras and Nicaragua, Xinka, Lenca, Matagalpa, Xicaque, Paya, Mosquito, Ulva, Chibchan.

Culture.—The culture of the American Indians, like that of any large group, is so complex that a descriptive review is inadequate in proportion as it is compact. This culture is therefore perhaps best considered from the point of view of how its constituents classify as to origin—elements common to America and

the Old World, peculiar to America, important in the Old World but lacking in the New, etc.

1. A series of simple culture traits are literally (or practically) universal among American tribes and of equally common occurrence in the Old World, and may be assumed to have formed part of the culture stock with which the first immigrants came into the hemisphere. These traits include the use of fire and the ability to make fire with the drill; the dog as a domesticated or semi-domesticated animal; stone implements for piercing, cutting, scraping, chopping; the spear, the spear-thrower, and probably the harpoon and bow; cordage, netting, and basketry; adolescence rites for boys and girls; shamanistic beliefs and practices. These elements survive in the more remote and backward portions of the eastern hemisphere, and for the most part have their relative antiquity attested directly by archaeology, carrying back to the end of the Palaeolithic or beginning of the Neolithic period.

2. Equally well defined is a class of culture traits which are widespread in the eastern hemisphere, in fact practically universal in all parts possessing a sufficient development, but are totally lacking in both North and South America. These elements evidently originated in the Old World subsequent to the movement which mainly populated America; they were not for some reason, perhaps chiefly because of the inhospitable conditions and backwardness of culture in the region of Bering Sea, diffused into America. This class of traits includes all the important domesticated animals and plants excepting the dog, viz., cattle, sheep, the goat, pig, horse, ass, camel and even reindeer; wheat, barley, rice, etc.; the plough and the wheel; iron; stringed instruments. Environment may be held responsible for the absence of some of these from the western hemisphere; it cannot account for the non-existence of iron-working, the plough and the wheel.

3. The higher civilizations of America were reared on an economic and technological foundation of their own, evidently evolved in and largely remaining confined to the region of "Middle America," namely the area from Mexico to Peru. The basis of this civilization was a form of agriculture limited to a series of indigenous plants. Fundamental among these plants was maize, seemingly altered by domestication from a wild species native to the highlands of Mexico and Guatemala. Closely associated with maize were beans (*Phaseolus*) and pumpkins and squashes. These plants were cultivated by all the Indians of both Americas as far as agriculture was practised by them, from the St. Lawrence to the La Plata. In the tropical region there were cultivated in addition other important plants—the potato, sweet potato, manioc, tomato, pineapple, chili pepper, tobacco, chocolate, etc. All this agriculture was practised without implements more complicated than a hoe or simple planting stick; it was strictly a hand culture. Domesticated animals were lacking, except for the llama and alpaca in Peru and the turkey in Mexico. Copper, gold, silver, platinum, tin and lead were smelted, cast, plated and alloyed in middle America; in other words, the metallurgical arts of the Old World prior to the iron age were known. Cotton, of another species than the cotton of the Old World, had been domesticated in middle America and was the basis of an elaborate textile art, operating however with simple apparatus; and clothing was of types based upon true fabrics instead of skins or bast fibres. Pottery shows a wide distribution almost identical with that of agriculture; archaeologically, it is generally associated with agricultural remains; and it may therefore be assumed to have originated in middle America at about the same time as agriculture. Masonry had spread somewhat beyond middle America as far as north-western Argentina and south-western United States.

Middle America was the region of cities, therefore of higher political organization, and in Mexico and Peru of considerable empires. In the same regions ritualistic religion, including altars, permanent edifices, sacrifices and symbolism, reached its most complex development. This development was evidently dependent upon the existence of a priesthood persisting through successive generations under stable social and political conditions. Finally, the intellectual achievements, probably also in large part due to priests, culminated in the mathematical and calendrical systems

of the Maya, and in an incipient system of writing employed by them and the neighbouring Mexican nations. Attempts have been made to derive these products of learning from the Old World; but analysis shows their principles, especially those of the calendar, to be unique. The Maya, for instance, had devised position numerals and a sign for zero; but their system of numeration was vigesimal. Also, they were using this system by the beginning of the Christian era, centuries before any people in the Old World had invented a sign for zero.

4. Other culture traits in America, not specially characteristic of higher civilization, do not occur regularly distributed in or around the Mexican-Peruvian area. Some of these traits may be presumed as due to local inventions independent of the middle American stimulus. Others may have originated earlier than the middle American agriculture-metal-town-priesthood growth and have diffused irregularly, or perpetuated themselves only in certain tracts. Most elements peculiar to one or two culture areas (see below) fall into the present class; for instance, the carpentering, wood-carving and frame houses of the North Pacific coast; the special war customs of the eastern United States; the acorn food technique of California. Clan systems or exogamic institutions, usually with totemic manifestations, occur in North America in several areas: the south-east and north-east, the North Pacific coast, in a limited area in the plains, and somewhat doubtfully in certain parts of Mexico.

5. A certain number of traits restricted to the north-western half of North America show modern or recent analogues in the Old World, usually in northern Asia and Europe, but do not appear to possess prehistoric antiquity. They may therefore be assumed as importations into America, mainly by diffusion rather than by migration, in the last few thousand years. For the most part these traits are distinguishable without difficulty from the universal and supposedly very ancient ones of class 1. Into the present group there may fall the sinew-backed bow (the supposed American equivalent of the composite bow of Asia), the tepee or skin tent on poles, the snow-shoe and toboggan (equivalent of Old World snow-shoe of ski type), birch bark canoes and vessels, the half-underground house roofed with earth, tailored or fitted clothing of sewn skins, perhaps coiled basketry, and several myth episodes such as "Earth Diving" and the "Magic Flight." The distribution of most of these traits in America stops before it reaches the south-west and south-east United States. None of them had reached the advanced portions of Mexico.

Culture Types.—An attempt has been made by Americanists to organize the complex and irregular manifestations of native culture by classifying them into certain types characteristic of regions known as culture areas. These are to a certain degree environmental; the natural environment is thought to have acted as a stabilizing and perpetuating factor, once a certain type of culture had been achieved in an area. Essentially, however, this classification is one of culture types, and the concordant geographical areas largely represent empirical determinations of distribution. In this respect the culture area classification, as first formulated by Wissler and accepted with only minor modifications by practically all American students, differs from older attempts which proceeded from environment as the supposed determinative factor (see O. T. Mason's article "Environment," in the *Handbook of American Indians*). The more important types of culture in these areas are outlined in separate articles. The areas are: 1, Mexican, north about as far as the Tropic of Cancer (see AZTEC, TOLTEC, MAYA, ZAPOTEC); 2, South-west (i.e., of the United States, but including northern Mexico; see PUEBLO); 3, 4, South-east and North-east, perhaps to be joined and called Eastern woodland (see MUSKOGIAN, MOUND BUILDER, IROQUOIS); 5, Plains (q.v.), in the untimbered centre of the continent; 6, Plateau, in the western inter-mountain region, an area relatively undifferentiated in culture, with actively entering influences from the adjacent areas (the Great Basin is sometimes separated from the upper Columbia and Frazer region and united with California); 7, California; 8, North Pacific Coast (q.v.), from northern California to southern Alaska inclusive; 9, Mackenzie-Yukon (see ATHABASCAN); 10, Arctic (see ESKIMO). The West

Indies seem to belong culturally with South rather than with North America. The southern frontier of the Mexican area may be placed in Nicaragua, Costa Rica and Panama forming part of the Chibcha or Colombian area of South America. In this continent there may be recognized: 1, Chibcha or Colombian; 2, Andean (southern Ecuador, Peru, highlands of Bolivia, north-west Argentine, northern Chile); 3, Patagonian, a hunting area dependent largely on the guanaco; 4, Orinoco-Amazonian, where manioc disputed the supremacy with maize; 5, Antillean or West Indian.

Temperament.—This is notoriously difficult to dissociate from culture habits, but there appears to be a fairly general agreement as to a characteristic American type of mind and personality, though it might be arguable how far this is innate. Almost universally the American Indian is reserved, stoic, enduring and unresponsive, the antithesis of the negro, and more similar to the Mongolian in behaviour than to the Caucasian. He is not without humour, but holds expressions of it in rigorous check, so that it becomes manifest chiefly in intimacy. He is patient but not quick; tough in adversity but unenterprising; stable but unimaginative; cruel when his inhibitions have been removed, but not given to brutality ordinarily. He prizes control as the highest virtue, and restraint and decorum as the essentials of manners, and therefore almost always impresses as imbued with unusual sense of respect of personality.

Population.—The original numbers of the American Indians are imperfectly known. The most complete and careful count, that by Mooney (*Smithsonian Misc. Coll.*, lxxx., 1928) arrives at a total of 1,150,000 souls north of Mexico at the time of first contact with Europeans. Inasmuch as several specialists have set a somewhat lower figure for the regions with which they were most familiar, Mooney's total is probably too large rather than too small, and one million in the United States and Canada is, perhaps, not far from the true number. In Mexico and in Central America population was much denser relatively and absolutely; it cannot well be put at less than three to four million. Similar conditions prevailed in South America: there may have been nearly as many natives in Peru as in the remainder of the continent.

In general, the race has declined after contact with Europeans. Some North American tribes have become completely extinct. Many others have shrunk to such an extent as to have lost their identity and merged with other tribes. Some have partly held their own, others wholly so, and a few, like the Navaho, have indubitably increased. The conditions to which each tribe was subjected must be known in detail before the reasons for this variety of fortune are intelligible. In most tribes there has been a heavy infusion of white and sometimes of negro blood. Except in the south-west, it may be said that even those tribes that remain as numerous as originally, are so only through the inclusion of alien blood. Socially the mixed bloods generally are Indians. Of this population of pure and mixed blood, there remains not quite half a million in the United States and Canada. Mexico is estimated to be about one-third pure Indian, and more than another third, part Indian.

History.—There is no native documented history of the American Indian, except for the Aztec and Maya. The great bulk of the tribes possessed neither time systems nor writing, and left only legendary traditions. These usually possess a certain authenticity. In the main the history of the tribes is a history of their contacts with Caucasians. Often more can be gathered as to the movements or other fortunes of a stock, from its recent distribution and from the relations of its component languages, than from any directly historical source. (See for instance ATHABASCAN, UTO-AZTECAN, ALGONKIN, SIOUAN, MUSKOGIAN, IROQUOIS.)

Native history resting on a documentary basis has been preserved only in the Mexican region. The Maya left both monuments with dated inscriptions and post-Spanish chronicles. The calendar (q.v.) in which the inscriptions are expressed is extremely accurate and is well known. Its conversion into our chronology is not quite so certain, the evidence bearing on this point being somewhat conflicting as well as incomplete. According to the correlation accepted by most specialists, the Maya cities of the

Old Great period, which have left the principal dated inscriptions, flourished from the first to the end of the 6th century after Christ. The earliest date found converts to 96 B.C. This calendar system involves long observation, some historical knowledge, considerable facility in computing, and is accompanied by hieroglyphic writing, fine sculpture, and advanced architecture. In short, Maya civilization had already taken shape by the beginning of the Christian era. Beyond this was most likely a formative period as yet unknown, and back of this an Archaic period of which the first traces are apparently beginning to be discovered. The principal other system of chronological conversion interprets all Maya dates as about 270 years earlier.

An Archaic period is well known from remains in the valley of Mexico. This, however, was a culture already emerged from primitiveness, since it possessed agriculture and pottery. There is nothing to fix its period, except that its freedom from Maya influence argues its being anterior to the development of the characteristic Maya civilization. It was succeeded by the more advanced culture of the Toltecs (Teotihuacan), and on this legendary data were preserved by the still later Aztecs. Some of the Aztec accounts are chronological and carry Toltec history back to about A.D. 600, with a period of florescence around A.D. 900-1000. The Toltec-Aztec calendar, however, while absolutely accurate within its cycles of 52 years, did not with certainty distinguish successive cycles, so that all Toltec dates must be accepted as being only approximations.

In the south-western United States, Pueblo and pre-Pueblo culture have been unravelled by intensive archaeological work, until a series of seven stages is now known, the first being one without pottery and with an estimated age of about 3,500 years. None of the Pueblo periods, however, are as yet really datable.

BIBLIOGRAPHY.—The most important general work of reference is the *Handbook of American Indians*, published by the Bureau of American Ethnology as Bulletin 30 in two parts (1907 and 1910). The basic work on linguistic classification is by Powell, *7th Report of the Bureau of American Ethnology* (1891). As regards culture, the points of view here adhered to were first outlined by Boas in a brief article, "The History of the American Race" (*N.Y. Acad. Sci.*, xxi., 1912); supplemented in the *Intern. Congr. Americanists*, xxi. (Göteborg, 1925); and are most fully developed, with special emphasis on the culture areas and with attention also to racial and linguistic factors, in Wissler, *The American Indian* (1917; 2nd ed., 1922). Supplementary considerations will be found in Wissler, *Man and Culture* (1923), and *The Relation of Nature to Man in Aboriginal America* (1926). Farrand, *The Basis of American History*, gives the natural setting. Brief comprehensive works on special areas are Goddard, *Indians of the South-west*, *Indians of the North-west*; Wissler, *Indians of the Plains*; Spinden, *Ancient Civilizations of Mexico* (these four are *Handbooks of the American Museum of Natural History*) Kroeber, *Handbook of the Indians of California*, *Bur. Amer. Ethn. Bull.* 78; Kidder, *South-western Archaeology* (1924). Numerous monographs and special articles are cited in the bibliographies included in these general works. (A. L. K.)

ARCHAEOLOGY

In recent years various remains attributed to early man within the area of the United States have been discovered, notable among which was the finding of the so-called "Lansing skeleton" in 1902 at Lansing, Kansas, at the base of the Missouri river bluffs, 20 feet below the surface and 60 and 70 feet from the mouth of a tunnel excavated for storage use. The place was visited and studied by several geologists and archaeologists, the geologists varying in opinion as to the age of the deposits and consequently the antiquity of the skeleton.

In Florida have been found various human remains to which extreme age has been ascribed, sometimes accompanied with objects of human handiwork. Some of these remains are more or less mineralized bones found near Osprey, Manatee county, on the west coast, from 1871 to 1887, and this fossilization has generally been regarded as an important indication of antiquity. The features of the crania, as well as of the other bones, show no material differences from those of recent Florida Indians.

In 1894 and 1906 were discovered remains of what became known as the "Nebraska Loess Man" in the Gilder Mound on a ridge above the Missouri river, 10 miles north of Omaha. These remains, some of them accompanied with crude flint im-

plements and chips, were found at varying depths, those below 4½ feet, to a depth of 11½ feet below the surface (the lowermost 5 feet, however, containing only scattered fragments of bone), being regarded by the explorers as contemporaneous with the loess formation and antedating the hill itself. Subsequent investigation of the site and of the skeletal materials therefrom seemed convincing that, regardless of their depth and the apparently undisturbed condition of the loess in which most of the remains were found, there is no substantial ground for belief in any considerable difference in the age of the upper and the lower bones; that the appearance of knife-marks on bones from both the superficial and the deeper layers suggest a custom such as post-mortem cleaning of the bones of the dead for secondary burial that could hardly have occurred at such remote periods as claimed, and that the many fragments of bones found deepest in the loess might well have been the result of the burrowing of rodents, evidences of which were present.

From an asphalt pit on Rancho La Brea, near Los Angeles, California, have been taken a vast number of bones of animals of the Quaternary period, and in 1914 widespread interest was aroused by the recovery therefrom of considerable parts of a human female skeleton. Although in such close association with the extinct animal remains, the human skull bears no features that mark it as other than that of an ordinary California Indian.

In 1913-1916 there were found at Vero, Florida, various vertebrate, invertebrate and plant fossils of Pleistocene age, together with fossilized human remains accompanied with implements and chipped flints, all in such association as to establish the basis of a claim of incontestable evidence of contemporaneity. Thus did the "Fossil Man of Vero" become widely exploited. The primary observations were made entirely from a geological point of view; subsequently other geologists, as well as anthropologists, investigated the site, and a thorough study of the skeletal remains for the first time was later made by Hrdlička, who, after examining the conditions under which they were deposited, was convinced that the burials were intentionally made in the fossil-bearing deposits long after the extinction of the animal species whose bones were found in association.

In 1924 remains of several human skeletons were found within an area of 12 square feet and at a depth of 19 to 23 feet, in excavation for an outfall sewer near Los Angeles, California. Fortunately it was possible to make scientific observations on the spot immediately, and by study of the local geological conditions it became evident that the presence of the osseous material, rather than being washed in, was due to miring under bog conditions, presumably prior to the accumulation of the greater portion of the deposits that overlay the human remains. No indication

FROM "PAPERS" OF THE PEABODY MUSEUM
CAHOKIA MOUND, IN ILLINOIS, LOOKING WEST: THE LARGEST PRE-HISTORIC EARTH-WORK IN AMERICA

of Pleistocene or of recent mammals was found in association. The conclusions reached by Professor Stock were that the evidence did not point unequivocally to Pleistocene age of the deposits containing the human material, but that they might well be measured in terms of thousands of years, but not necessarily tens of thousands.

In 1923-1924 the nearly complete and articulated skeleton of a Pleistocene bison was found on Lone Wolf creek, near Colorado, Mitchell county, Texas, embedded in an indurated matrix of cemented sands, gravels and clays, beneath which were two thin,

well-chipped, flint projectile points and part of another. In 1925 an almost identical discovery was made in the bank of an arroyo near Folsom, New Mexico, the two implements there found in direct association with fossil bison being even finer examples of chipping than those which came from Texas. The excavations at Folsom are still in progress. These two interesting discoveries are quite comparable, so far as the circumstances are

FROM "A JOURNAL OF AMERICAN ETHNOLOGY AND ARCHAEOLOGY," 1932

RUINS OF AN EARLY ABORIGINAL DWELLING "THE BIG HOUSE," AT CASAS GRANDES, MEXICO

The building probably reached a height of six or seven storeys, and is constructed of sun-dried blocks of mud and gravel. Its age has not been determined beyond the fact that it was already in ruins at the time of the Spanish conquest

yet known, to the finding of a somewhat cruder spear-point, likewise found in connection with a fossil bison, at Russell Springs, Logan county, Kansas, in 1895. Again, in 1926, near Frederick, Tillman county, Oklahoma, there were reported to have been found, near the base of a great hilltop gravel and sand deposit, 10 to 25 feet in thickness, in a stratum containing fossil vertebrates and beneath a layer of sandstone, a chipped flint spear-point, together with two stones described as "pestles or grinding instruments," which were not regarded as of sufficient importance to preserve. Above the sandstone, in partially cemented sand, gravel, and pebbles, 9 to 15 feet thick and likewise containing fossils, a flint drill-point was found. In the same stratum, 8 feet beneath mammoth remains, were unearthed five specimens of what were identified as metates, or mealing slabs, of sandstone. No human skeletal remains were anywhere present. Mr. Harold J. Cook regards these artifacts as earlier representatives of Pleistocene man than those found in Texas and New Mexico, which follow in order in point of age; he believes that the Frederick deposits are of early Pleistocene age, probably Aftonian.

DISTRIBUTION OF CULTURES

Archaeological research has been widely conducted north of Mexico; but the territory is so vast, the tribes and bands were so numerous and their shiftings so many, that knowledge of the archaeology of many areas is still almost a blank. Enough has been gleaned, however, to enable a fair classification of the character and distribution of the cultures in prehistoric times, and in many instances it has been possible, by analogy with the arts and customs of existing tribes or through historical research, to identify the peoples whose remains were under investigation.

There is general agreement with respect to the limits of the various archaeological culture areas north of Mexico, such differences as are due to more or less marginal influence not materially affecting the general classification. Furthermore, a close correlation is shown in the archaeological culture areas and those of the historic tribes. Within the limited area of this treatment the Indians had no records beyond arbitrary, and for the greater part undecipherable picture-writings, hence archaeology at best can hardly be relied on to present a vivid picture of the life of the northern Indians before the coming of white men. In a comparatively few instances Indians occupied dry caves and rock-shelters in which

have been found examples of almost everything they made, of their foods, as well indeed as the bones of the occupants, thus enabling determination of at least the approximate relationship of the crania, affording an opportunity to reconstruct much of the life of the people, and of estimating the relative periods of occupancy through study of the stratigraphy of the deposits. While archaeology has revealed a relatively high degree of culture in certain areas north of Mexico, notably in those of the mound-building tribes and of the Pueblos of the Southwest, yet in no instance did it equal that of Mexico and Central America, where the ancient cultures were characterized by stupendous buildings of elaborate architecture, by glyphic writing, and by works of art in stone, wood, mural and other painting, and ceramics, in many respects equal to the highest art of early times in the Old World.

Culture Areas.—Based on the more clearly manifested phases of their culture content, the following eleven general archaeological areas north of Mexico as set forth by Holmes, have been recognized, the classification varying in no great degree from that based on ethnological observations as mapped by Wissler: (I.) North Atlantic area; (II.) Georgia-Florida area; (III.) Middle and Lower Mississippi Valley area; (IV.) Upper Mississippi and Great Lakes area; (V.) Plains and Rocky Mountains; (VI.) Arid region; (VII.) California area; (VIII.) Columbia-Fraser area; (IX.) Northwest Coast area; (X.) Arctic Coastal area; (XI.) Northern Interior area. This general classification well serves the present purpose.

I. North Atlantic Area: This culture area, sometimes divided into two at the Delaware valley and sometimes into still lesser areas, may be regarded as extending from Newfoundland and the St. Lawrence valley in the north to southern Georgia in the south, and as including the Maritime Provinces of Canada, New England, New York, Pennsylvania, Maryland and large portions of Virginia, West Virginia, the Carolinas and Georgia, the northern part of the territory extending inland indefinitely to the north and west, and its southern part extending westward to the Appalachian mountains. The tribes were chiefly those of the Algonkin, Iroquoian and (in the south) Siouan stocks of historic times, and save for certain shiftings of boundaries and the extinction especially of most of the Algonkin and Siouan members,

FROM BUREAU OF AMERICAN ETHNOLOGY
—REPORT—

AN IROQUOIS VASE, 13 IN. IN HEIGHT, FOUND IN A GRAVE IN NORTHERN PENNSYLVANIA

the archaeological and known linguistic areas may be regarded as practically coextensive. The forests and highlands afforded excellent hunting; the many rivers and bays, and the sea itself, offered an abundance of fish and shellfish, and while agriculture was practised, it was subordinate to fishing and the chase. Shellfish (oysters, clams, mussels, scallops, whelks, cockles) formed an important part of the diet, as shown by the almost numberless heaps of shell refuse along the coast and the tidewater bays, rivers and inlets. One heap at Pope's creek on the Potomac in Maryland, consisting of oyster-shells, covered about 30 acres and reached a depth of 15 feet. The Peninsular shell-mound, one of five principal deposits of oyster-shells on the west bank of Damariscotta river, Maine, is about 400 feet long and attains a maximum height of 22 feet.

The dwellings of the ancient Indians of the North Atlantic area probably varied in no respect from those of early historic times. Stone as a building material was almost unknown, construction being of wattlework, bark, and mats, and the Iroquois villages were often protected with stockades. Cache pits for storage were used in the central part of the area, centring in New Jersey. Some of the houses, as those of the Iroquois, the

Mohican, and of Virginia and North Carolina tribes, were of the community type, those of the Iroquois (the well-known "long-houses") being 50 to 100 feet long and 16 to 18 feet wide.

Burial customs varied more or less with locality, but interment was the usual practice; sometimes the corpse, fully clothed, was placed in the grave in a sitting posture. The custom of the Algonkin and Iroquois tribes from the St. Lawrence to the Delaware was to wrap the corpse and to bind the legs against the trunk, and sometimes, except among the early Algonkins who rarely practised the custom, the implements, utensils, and ornaments of the departed were buried with his remains. Interment of dogs, sometimes with the human dead, was common. In the Iroquois area especially the bones of the dead were periodically gathered from their graves and deposited in ossuaries lined with furs and covered with brush and earth, but this was not an Algonkin custom. Among the Powhatan tribes of Virginia two methods of disposal were practised in prehistoric times as well as at the beginning of the Colonial period—the bodies of important men were wrapped and placed on platforms in the "temples," and probably afterward gathered and buried while those of ordinary people were at once inhumed.

In the lower Penobscot valley, in Maine, it was an ancient custom to place quantities of red hematite paint in the graves and to deposit with the dead certain exceptional stone objects only—long slender celts, gouge-adzes, and slate points of bayonet shape, resembling those of the Eskimo and even those of northern Europe and Asia. In the abundant shell-heaps of the region such slate points are unknown, and the other implements are either scarce or entirely lacking, whereas bone and shell objects so common to the shell-heaps are not found in the graves. These conditions have given rise to the designation "Red-paint people" to distinguish the earlier from the later inhabitants, not alone because the graves of the ancients contain the hematite deposits, for a similar custom was practised elsewhere in New England as late as Colonial times. There are certain indications that point to relationship with the extinct Beothuk of Newfoundland, as well as with the Algonkin culture of New York.

The ceramic art of the North Atlantic area was somewhat rudimentary in comparison with that of other cultures, yet the cooking utensils and the trumpet-like smoking pipes of the Iroquois display considerable taste, and the pipes especially were often elaborately decorated with modelled life forms or miniature jars. The typical Virginian pipe with long stem and upturned bowl, taken to England by early colonists along with the first tobacco, gave form to the common clay pipe of the present time. The chief distinguishing features of the ancient earthenware vessels of the Iroquois of New York and Pennsylvania are a conical base, constricted neck, and flaring squarish collar usually embellished with an incised rectilinear pattern and sometimes with modelled heads and figures in relief. In the marginal regions, —New York bay, Long Island, the lower Hudson valley, Connecticut, and Rhode Island,—the Algonkin pottery, otherwise usually plain in form and simply decorated by incising or with fabric-or-cord-marked impressions, often shows Iroquois influence.

Stone objects consisted of the pecked and polished celt-hatchet, grooved axe, chisel, pick, gouge-adze, mortar, long cylindrical pestle, knife and spearhead of slate, and hammer-stone; of these the gouge-adze is of exceptional excellence. Chipped stone implements of all the ordinary types (knives, projectile points, drills, etc.) were plentiful; objects of the same material used as ornaments or in ceremony were banner-stones, bird-shape stones, "plummets," tubes, pierced gorgets, etc. Not all of these objects are found throughout the area, their distribution depending on the varying sub-cultures of the former tribes and their chronological sequence. Human effigies of stone are rare. Soapstone (steatite) abounds, and owing to its suitability and the ease with which it may be fashioned, it was extensively quarried with stone pickaxes and chisels for manufacturing cooking-pots, smoking pipes and ornaments. Objects of bone, especially in the Iroquois area, are rich in form and variety. Mica was mined in Virginia and North Carolina for use especially in making ornaments and mirrors, and it became an important medium of

trade over a wide area, great quantities having been recovered from Ohio mounds. Argillite, jasper, and rhyolite were quarried in New Jersey, Pennsylvania, and New York, and quartz and quartzite boulder deposits in the District of Columbia and elsewhere for chipping into prodigious numbers of implements and weapons, especially arrow-points and celt-hatchets (tomahawks). Engraved conch-shell gorgets of Virginia and the Carolinas suggest culture intrusion from the west. Water transportation was by dugout and bark canoes. Petroglyphs, or rock-writings, are rather common, the most noted being Dighton Rock in Taunton river, Mass.

II. Georgia-Florida Area.—The southern part of Georgia and northern Florida were occupied by tribes of the Muskogin family, and the peninsula by the extinct Timucua and Calusa, with evidences on the west coast of early Arawakan intrusion from the West Indies, all of which have left their impress on the archaeology of the region. The antiquities are somewhat distinct from those of the North Atlantic area, but grade imperceptibly into those of the Gulf states to the west and the Mississippi valley area to the northwest. Agriculture was practised in suitable localities, but the waters of the extensive coast and of the streams afforded the principal food supply, and the refuse of feasts over long periods is still seen in the hundreds of shell-mounds along the coast and on some of the river banks.

Burial mounds of earth and sand are numerous, and have yielded many relics, especially in the peninsula, where it was the custom to place with the dead many crude objects of fired clay, vessels of fanciful shapes, and rude effigies of creatures or things real and fanciful, as mortuary offerings. Especially in west Florida large deposits of earthenware utensils are found with the dead, the forms sometimes suggesting a distinct type of mortuary vessel, and like those of the peninsula, they were often perforated in the bottom, or "killed." Methods of burial varied: the body was (1) extended, or (2) flexed; (3) it was exposed until the flesh decayed, when the bones were gathered and interred; (4) the remains were cremated. Urn burial, of cremated or non-cremated remains, common in Georgia, was rare on the peninsula.

The houses were built of poles and thatch, often in circular village groups and surrounded by palisades as a means of defence; but only traces of these have been found. Along the Gulf coast pile-dwellings also were once used. Pottery, sometimes of pleasing forms, but not painted, was extensively manufactured, and in the western part of the area life forms were skilfully modelled,

AFTER HOLMES

GENERAL VIEW SHOWING PROGRESS IN REMOVING SHELLS AND LODGE-SITE REMNANTS AT POPE'S CREEK SHELL-HEAP

and engraved and indented designs were used. Elsewhere the surfaces of vessels were embellished with the figured stamp or paddle, some of which are so closely analogous in motive, grouping, and execution to certain designs on wooden objects from the West Indies as to create the belief that they could have arisen only through identity or by intimate relationship of the peoples employing them. Traces of distinctive Caribbean treatment and motive are found almost as far north as the boundary of Virginia and South Carolina, in the valley of the Tennessee near Knoxville, and westward on the Gulf coast in southeastern

Alabama. Earthenware pipes are usually of angular trumpet shapes with bowls expanded into human or animal heads, but in west Florida they were more clumsily made.

Finely carved stone bowls and strange plates with ornamented rims have been found; but stone sculptures are exceptional, hence earthenware forms the chief basis of study of the culture status of the early inhabitants of the region. By the recovery of various remarkable masks, figurines, dishes, stools, and other carved and painted wooden objects from the canal muck on Key Marco, on the southwest Florida coast, in a region occupied by the Calusa in late prehistoric and early historic time, a degree of art was attained that is not suggested by the stone and pottery articles of the area, making it probable that the culture represented by these objects and by those of shell and bone found in association, was exotic. Cutting and incising tools of shell and of sharks' teeth appear to have been the main reliance of the craftsmen of the Florida keys, some of whose products bear patterns identical in motive with designs found in the West Indies.

In the northern part of the culture area flint was utilized for the manufacture of the usual kinds of chipped implements, a phenomenal abundance of which is found in Georgia. Only in limited areas are found the varieties of stone usually employed in manufacturing the pecked-ground implements, hence tools of this kind are comparatively rare, with the exception of the celt. The grooved axe also is of rare occurrence, although abundant in the northern sections of most of the Gulf states, where it is closely associated with the celt. Comparison has been made with the occurrence of great numbers of celts and the rarity of the grooved axe in the West Indies, the celts from those islands and from Florida bearing closer resemblance than those from any of the more northerly districts, hence suggesting insular influence as in the case of the pottery. A further suggestion of intrusion of culture is the occurrence in Florida, and in other Gulf states, of a perforated hoe-shape stone implement which corresponds closely with a type of axe prevalent in South America, and pile-dwellings in the south and suggestions of the practice of cannibalism on St. Johns river point in the same direction. Wood commonly took the place of stone in fashioning mortars and pestles. Ornaments of gold and silver have been found in the peninsula, and while some of the more elaborate pieces may have been derived from Mexico or Central America, the skill of the Florida metal-workers is shown by objects of wood and bone overlaid with sheet-copper, and by certain plates of sheet-copper with symbolic devices executed in repoussé fashion with much precision. As in the ceramic art, the metal-work of the South Atlantic area indicates a higher degree of culture than that of the northern area.

III. Middle and Lower Mississippi Valley Area.—This interior area, with much outlying territory, is characterized by remains which in many respects represent the highest culture attained by any of the aboriginal peoples north of central Mexico. This is what is commonly known as the mound-builder culture, exemplified by many earthworks of varying forms and magnitude, and designed by their sedentary builders for domiciliary, religious, civic, defensive, and mortuary uses, and in some instances no doubt as places of refuge in times of flood. Effigy mounds, numerous in the Upper Mississippi and Great Lakes area, are uncommon; the Serpent Mound is notable. The builders of the mounds were long regarded as a race distinct from the Indians,

but archaeological investigation has proved that these tumuli are solely the product of the Indians: that indeed many of them south of the Ohio valley were in use and even in process of erection after the coming of Europeans, as attested by the finding of articles of civilization as original inclusions. Tribes of this region known to have occupied the mound area and to have been builders of earthworks belonged to the Siouan, Algonkin, Iroquoian, Muskogin, Tunican, Chitimachan and Caddoan linguistic families, and these may have been preceded by other Indian groups in prehistoric times.

The culture of this area cannot be said to be confined strictly to the region designated, for in certain of its typical aspects it extends to the Georgia coast, blending with that of the Florida area, and to the coast of other Gulf states. The culture likewise has much in common with that of the Upper Mississippi and Great Lakes area, and grades somewhat abruptly into that of the adjacent region of the west. Although presenting more or less homogeneity throughout, the Lower Mississippi area is not a simple culture unit, for there are a number of localized centres of development and differentiation, no one of which can yet be selected as the type for the entire area. Aside from the more typical forms of culture, there are limited areas in which very primitive conditions seemed to have prevailed down to the advent of Europeans; and there are some indications, in various parts of this area, of culture relations with Mexico.

Of the character of the domiciles and temples of the mound-building Indians little is known, for, unlike the earthworks, being of a more or less temporary character, practically nothing of them has survived. It is known however from early descriptions that buildings of the Natchez of Mississippi and of other tribes were of wattlework faced with clay, and with roofs of bark and thatch—materials that soon decayed. Of similar materials probably were the buildings associated with the great earthworks—Cahokia in Illinois, Etowah in Georgia and Marietta, Newark, and Fort Ancient in Ohio. Remains of stockades that supplemented the embankments in defensive works and served to protect the villages from attack have been found. Modes of burial within the mound area were extremely varied, and vast numbers of artifacts were deposited as offerings with the dead in ordinary cemeteries, in stone graves, and in mounds of earth and stone.

Art in stone was well developed, although sculpture of the human form had made but slight advance, except in the case of the smoking pipes, where exceptional skill is shown both in this respect and in the production of animal effigies. Stone was employed in a limited way in the building of walls and fortifications and in the construction of graves, and desirable varieties were quarried on a large scale for the manufacture of implements, utensils, and ornaments, and also objects pertaining to religion and ceremony. Chert was quarried almost throughout the area; hematite ore for implements and ochre for paint were procured in Missouri; granitic and other durable rocks were distributed over the northern borders by ice-sheets of the glacial period and were utilized by the inhabitants for implement-making. Copper from the Lake Superior region found an important place in the native arts and remarkable skill was shown in its manipulation by the metal-working processes. Among examples of copper work found in the

Hopewell mounds in Ohio, are a head-dress consisting of a high frontal piece made of sheets of copper covered with indented figures out of which rise a pair of wooden antlers neatly plated with sheet copper; certain spool-like objects, probably ear-ornaments, each skilfully formed of thin sheets of copper over a wooden base; and artificial copper noses on two skeletons and a necklace of 320 pearls. At the Mound City group, a few miles

eastward, three sets of copper antlers belonging to head-dresses were unearthed. Personal ornaments of the same material from the mounds are of great variety, including beads, pendants, pins, ear-ornaments, bracelets, gorgets, etc.; but none of the copper objects are more remarkable than the repoussé figures in sheet-copper, some of which suggest Mexican influence.

The presence of quantities of mica in the mounds of the middle region show that the inhabitants procured that desirable and readily worked material from North Carolina. By reason of the abundance and variety of these materials, "the range of lithic artifacts," says Holmes, "is greater than in any other region north of the valley of Mexico. The sword-like blades of Tennessee approach the highest place among American chipped products, and the agricultural implements of the Illinois region constitute a unique and remarkable class without parallel in any country." Thus there are numberless implements for cutting, scraping, boring, piercing, digging and hammering; axes, celts, adzes, chisels, discoidal "chunky-stones" used in gaming, banner-stones, ornaments and tobacco pipes, in great variety and excellence of form, design and finish. As mortuary offerings hoards of stone implements have been found, one of the most noteworthy of which was a deposit, in an Ohio mound, of many hundreds of beautifully chipped obsidian implements, transported from unknown sources at least a thousand miles away. Another interesting mortuary deposit in one of the Hopewell mounds of Ohio consisted of more than 8,000 large flint discs. Pigment palettes from Alabama, and engraved shells and sculptured utensils of the middle districts are among many other art products of the mound-building Indians. Perhaps in pottery alone did these people fall short of the ancient Pueblos of the Southwest, yet the elaborately engraved and painted vases and effigy vessels, particularly those representing the human head, of the middle Mississippi region, and the scroll-decorated receptacles of the lower Mississippi and the Gulf coast, display both excellent taste and skill. Bottle-shape vases were a favourite form of receptacle. The stamp-decorated ware of the southern Appalachian region on the border of this and the southern Atlantic culture areas, is of great interest. For some of the more noteworthy earthworks see CAHOKIA MOUND; ETOWAH MOUND; GRAVE CREEK MOUND; FORT ANCIENT; NEWARK WORKS; ELEPHANT MOUND.

IV. Upper Mississippi and Great Lakes Area.—This archaeological culture area is less sharply differentiated from those adjacent than are the others from their neighbouring cultures. The tribes inhabiting the region when first explored belonged to the Algonkin and Siouan stocks, and many Indians of the former still dwell within the domain, the ancestors of the Chipewya having forced the Sioux westward at the beginning of the

18th century. In a general way the ancient culture, as revealed by artifacts and other remains, is almost equal to that of the territory to the eastward, but is inferior on the whole to that of the Middle and Lower Mississippi area. Agriculture was practised in favourable localities, and the so-called garden beds of Michigan, ridged or furrowed tracts, are among the most novel and mysterious features of the archaeology of the area. But

hunting, fishing and seed-gathering, especially of wild rice, were the chief means of livelihood. Burial mounds of ordinary forms are widely distributed, and monumental features of unique type, including groups and chains of earthworks in formal and puzzling arrangements, and animal-shape mounds confined largely to Wisconsin, are abundant, such as the so-called Elephant Mound (q.v.).

This area was the source of two kinds of highly valuable raw materials that were extensively quarried or mined, and distributed far and wide—catlinite or red claystone in Pipestone county, Minnesota, and copper of the Lake Superior region. Excavations for obtaining the catlinite, which was readily made into pipes, ceremonial objects and ornaments, extended along a narrow outcrop for nearly a mile. The quarrying was done with fragments of quartzite from the strata between which the seam of catlinite lay, and which were roughly shaped for the purpose. The sites of the copper mines are marked by extensive pittings in exposing the copper-bearing rocks and breaking them up to release the masses of native copper by means of heavy boulders from the lake shore. Thousands of these rude hammers are found about the pits, and occasional specimens are grooved for hafting: The copper at first was worked to produce forms resembling those of the stone implements, but sooner or later the celts, hatchets, awls, knives, drills, spearheads and similar simple tools took on new forms and other varieties were evolved. The metal was too soft wholly to supersede stone as a material for the manufacture of implements, but its pleasing colour and other properties led to its use for personal ornaments, and by the time the whites arrived it had spread over the greater part of the country. Doubtless the material of most if not all of the remarkable objects of sheet-copper with repoussé designs, found in mounds and graves from Illinois to Florida, had its source in the Lake Superior workings.

The stone implements and utensils of the area include rude mortars and cylindrical pestles, grooved axes, celts, adzes, tobacco pipes, tubes and the usual range of ceremonial and talismanic objects, noteworthy among which are certain saddle-shape stones which, together with other problematical forms, are characteristic of the ancient Algonkin area. The fluted axe and the faceted celt are peculiar to this region. Deposits of flint were worked in many places and chipped implements of usual types are exceedingly plentiful. Quartz veins were worked at an early period about the Little Falls of the Mississippi, and crudely chipped implements thereof found in flood-plain deposits of the vicinity have led some geologists to attribute to them geological age. Pottery receptacles are of distinctive types and generally are more primitive in make than is the ware in the Lower Mississippi area; but in some localities the vessels were carefully finished and decorated with incised and indented figures, though painted examples are rare.

V. Great Plains and Rocky Mountain Area.—The cultures of the territories surrounding the Great Plains—the sedentary mound and Pueblo cultures, and the cultures of the California and Columbia-Fraser areas—gradually fade out; for excepting limited areas in the larger eastern valleys of the area, agriculture was not practicable, but the teeming herds of bison and antelope, and an abundance of other game animals, afforded an adequate food supply, and even the tribes that practised agriculture to any extent seem to have depended more on hunting than on the

FROM BUREAU OF AMERICAN ETHNOLOGY
"REPORT"

EARTHEN VESSEL OF THE MID-
MISSISSIPPI VALLEY, FINISHED IN
COLOUR

product of tillage. The Great Plains therefore were occupied largely by Indians who dwelt in *tipis* and were largely nomadic.

The time of the advent of the various tribes of this region is not known, but the semi-sedentary Caddoan peoples—the Pawnee of Nebraska, the Wichita of Kansas and other Caddoan tribes of Arkansas, Oklahoma and Texas—occupied their historically known seats from much earlier times. While Apache bands were met on the western Texas plains when the Spaniards first explored the country in the 16th century, they probably did not pass westward into New Mexico and Arizona until later; and the Comanche did not appear in the southern plains until the beginning of the 18th century. The only houses of the entire region that approached permanency were the earth-lodges, 30 to 60 feet in diameter, of the Pawnee and Omaha of Nebraska, the Ponca of Nebraska and South Dakota, the Osage of Missouri-Arkansas, and the Arikara, Mandan and Hidatsa of the upper Missouri river in North Dakota. Remains of these are still traceable at old undisturbed village-sites, in the form of rings, for the floor of the earth-lodge was sunk two to four feet below the surface.

Quarries of flint with associated sites of manufacture of chipped implements are found in Oklahoma, Kansas and Texas, and of quartzite and soapstone in Wyoming, the diggings for the quartzite being very extensive. Two remarkable deposits, or caches, of flint implements have been found within the region, one consisting of a thousand specimens in a sulphur spring at Afton, Oklahoma, the other a cache of thousands of flint arrow-points in Delaware county of the same state. Obsidian, a favoured material for projectile points and knives, is abundant in Yellowstone Park and the upper valleys of Snake river, Wyoming and was not only used locally, but found its way by channels of aboriginal barter hundreds of miles from its place of origin. The stone implements of the general Plains region reflect the hunting tendencies of the Indians that inhabited it—arrow- and spear-points, knives, scrapers, hammers, club-heads. The heavy grooved hammer used in early as well as in historic times for cracking the bones of the larger mammals for extracting the marrow, for driving stakes, and for pounding seeds, etc., is regarded as probably the most typical and characteristic of the stone tools of this culture area. The hafted stone hammer, used as a club, is thought to have been of somewhat recent introduction. The metate and mano, used for grinding corn by the agricultural Pueblos of the arid region, found their way to a slight extent into the mountains and plains to the north and east, and other evidences of a lowly Pueblo culture have been traced to western Texas. In the upper Missouri valley have been found indications of an overflow of such stone objects as tubular tobacco pipes and paddle-shaped clubs, more characteristic of the middle Pacific slope region of Oregon and Washington. In the great central reaches of the area are found circles and lines of boulders, with an occasional effigy in outline. The so-called "Medicine Wheel" in the Big Horn mountains of Wyoming, with a circumference of 245 feet, is notable. Some of the lines of stones doubtless mark the sites of buffalo pounds, while the small circles may indicate the sites of *tipis*. Pictographs are not uncommon. Pottery is rare throughout the area, excepting in its eastern fringe, where the western limits of mound-building Indians were reached.

Perhaps no more ancient remains have been found in the area than those recovered from certain dry rock-shelters in the Ozark mountains of western Missouri-Arkansas, which were conducive to the preservation of practically everything their inhabitants used—basketry, cradle-boards of cane, woven bags, fish-nets, overshoes and sandals of grass, moccasins of deerskin, feather robes, pendants and beads of shell, and stone spears which were hurled with an *atlatl*, or throwing-stick, for they hunted buffalo, elk, deer and turkey. These Bluff-dwellers were agriculturists as well as hunters, raising corn, beans and squashes, and using also for food many wild vegetable products. Little pottery was used. Adjacent caves revealed a later but still prehistoric culture, shown by the presence of the bow instead of the *atlatl*, and of a superior class of pottery, which may be attributable to the ancestors of the Osage or the Kansa.

In the southernmost part of the Plains area, in Texas, little intensive research has been conducted. Throughout the limestone region are found numerous and extensive kitchen-middens which give evidence of a hunter culture only; but along the streams of the central part of the state are many old camp-sites which reveal evidences of a superior culture. In the timber region of eastern Texas are evidences of an early mound-builder culture and of the relatively settled village culture of the historic period; and in the trans-Pecos and Panhandle regions a low form of Pueblo culture has been revealed, with some evidence of Basket-maker life.

VI. The Arid Region.—This area may be said to comprise the present Arizona, New Mexico, Nevada, southern Colorado and Utah, a part of western Texas, and northern Chihuahua. It is largely a region of desert plains, plateaux, cañons, mesas and lofty forested mountains, with here and there perennially or intermittently watered valleys of remarkable fertility when brought under irrigation. In its physiographic features as a whole the territory is quite unlike any other in North America, and therefore the culture of its ancient inhabitants stands alone.

The basic element of the culture growth, maize agriculture, was derived from the south and was taken up, fifteen to twenty centuries before Christ, by a previously resident long-headed, nomadic or semi-nomadic people of a culture perhaps not unlike that of the present desert Shoshoneans of Nevada, who did not practise skull deformation, and made excellent coiled basketry, sandals and twined woven bags, and used the *atlatl* or throwing-stick in lieu of the bow, but whose dwellings were of an unsubstantial character. This postulated stage has been termed *Basket-maker I.*, or *Early Basket-maker*.

The newly-acquired art of agriculture led to a more settled life and to the development of more permanent houses; but as yet pottery-making was unknown. This stage, *Basket-maker II.*, is exemplified by remains found especially in south-central and south-eastern Utah and in north-eastern Arizona.

At a later date pottery was introduced or possibly independently invented; houses of the pit type, "slab-houses" with pole-and-brush roof, were perfected and became grouped into villages, and bow and arrow began to supplant the throwing-stick; but the long-headed people still persisted. This was *Basket-maker III.*, or *Late Basket-maker*, remains of which are found throughout the San Juan drainage of Utah, Colorado, Arizona and New Mexico, and in parts of the Little Colorado watershed in Arizona.

At a still later period skull-deformation was initiated (some believe that a new broad-headed strain superseded the ancient long heads); cotton was introduced; dwellings emerged from the

ground, rooms became rectangular and were grouped more closely; structural coils were left unobliterated on cooking vessels and thus corrugated pottery originated. This stage, *Pueblo I.*, or *Proto-Pueblo*, is represented by sites throughout the San Juan drainage and in parts of the Rio Grande, Little Colorado and upper Gila valleys. Black-on-white and neck-coiled pottery is characteristic of the period, and the *kiva*, or ceremonial chamber, had its beginning.

The development of culture was rapid. A period of wide geographical extension marked by small-village life; corrugated pottery, often of elaborate technique, extended over the whole surface of cooking vessels. This culture stage was *Pueblo II*.

There was perhaps a decrease in the extent of territory occupied, and certainly a concentration of population in certain areas, together with greater architectural and ceramic achievement and strong regional specialization. This was *Pueblo III.*, the *Great Period*.

Subsequently large areas were abandoned, there appears to have been a considerable shrinkage of population, and there was a defi-

FROM BUREAU OF AMERICAN ETHNOLOGY
"REPORT"
VASE FROM PUEBLO VIEJO, GILA
VALLEY, ARIZONA

nite cultural degeneration. Corrugated pottery gradually disappeared. This period, *Pueblo IV.*, or *Proto-Historic*, was brought to a close by the colonization of the south-west by the Spaniards at the beginning of the 17th century.

The *Historic* or *Pueblo V.* stage is the period commencing with the Spanish settlement and continuing to the present time.

Thus were gradually evolved, over long periods, thousands of small houses built of masonry, associated with the ruins of which is black-on-white pottery that evidently originated in the San Juan drainage, spread in almost every direction until the culture represented by it extended roughly from Great Salt Lake and southern Colorado almost to the Texas border and southern New Mexico, eastward to the limits of New Mexico, and westward to the California boundary. Then concentration commenced, seemingly by the result of hostile pressure, resulting in large many-storied community pueblos, such as Pueblo Bonito and others in the Chaco cañon in New Mexico. Regardless of the sites, these pueblo clusters were built with a view of defense—on mesa-tops which were well-nigh impregnable, or in valleys convenient to tillage, where the character of the buildings, often terraced one above another with a well protected court and with outer walls having only a single opening, bespoke their defensive character. Many such villages were large enough to house a population of several hundred. To this day the Hopi villages and Acoma retain their mesa-top situations, and only within the last few decades have ground-floor openings been provided in place of ladders and hatchways. Some of the mesa-top pueblos were further protected by low masonry walls at vulnerable points of the cliff.

In addition to the use of stone as building material in the mesa and valley pueblos and in the cliff-dwellings, a form of concrete was used in constructing certain massive buildings in the southern area, such as the well-known Casa Grande in Arizona (the principal building of a large compound of circumvallated structures), the main walls of which, three to five feet thick, rise to a height of 20 to 25 feet, equivalent to two stories; but in 1699 it was four storeys high. The dimensions are 43 by 59 feet. Such edifices were erected by planting two rows of posts as far apart as the width of the walls was to be, wattling the posts with osiers, and filling this form, *pisé*-fashion, with mud made of the calcareous soil, which when dry became very hard. Moulded adobe bricks were not used in prehistoric times, but mud mixed with sage was rolled into the form of loaves and used for wall-building. "Wattle-and-daub" was occasionally employed for unexposed walls. The *kiva*, or ceremonial chamber, usually circular and wholly or partly subterranean, was a common feature of ancient as of modern pueblos, and their large number compared with the rectangular domiciles in cliff-dwellings, notably those of the Mesa Verde in Colorado, recalls early Spanish reference to their occupancy in the pueblos by the male inhabitants in addition to their use for religious rites. Especially in southern Arizona, the inhabitants of the villages composed of many large community clusters built of concrete like Casa Grande, cultivated extensively by means of irrigation, their canals sometimes extending for many miles and their storage reservoirs being of great capacity.

Sacrificial caves, pueblos, cliff-dwellings, and graves have yielded vast numbers of artifacts illustrating the ancient life and culture of the early peoples and have been of prime importance in determining chronological sequence. Taken as a whole the pottery (made without the wheel, of course) exceeds that of any other area north of central Mexico in grace of form, variety, range and execution of decoration, and, of the later periods, in colour. There were two periods during which the decoration was in glaze. On early vessels from the Mimbres valley, New Mexico,

FROM BUREAU OF AMERICAN ETHNOLOGY
"REPORT"

PITCHER WITH CHARACTERISTIC
INDIAN DESIGN FROM FOUR-MILE
RUIN, ARIZONA

are well executed representations of zoomorphic and other forms, and the pottery of the later polychrome period is often beautifully embellished with realistic as well as conventionalized figures of birds, feathers, and other motives in great variety. Effigy vessels are common to many localities and to various periods. The excellent basketry of the earliest stages of culture gave way largely to earthenware after the adoption of corn-raising and sedentary life became firmly established. The throwing-stick, or *atlaltl*, early superseded by bow and arrow, has been mentioned. Netted and woven articles of wild vegetable fibres, and fabrics of remarkable beauty sometimes interwoven with feathers after the early introduction and cultivation of cotton, exhibit the facility of the ancient inhabitants in the textile art. Stone slabs and vessels for preparing or containing paints and medicines are sometimes well finished and embellished in relief with effigies of birds, animals, serpents, and frogs; but sculpture generally was inferior to that of the Mississippi Valley tribes, the Pueblo hunting fetishes representing prey animals not equalling the remarkable effigy pipes from Ohio mounds. The most ambitious effort of Pueblo sculptors of old is shown in the partly destroyed crouching mountain-lions carved life-size in rock-in-place near Cochiti pueblo in the Rio Grande valley. Petroglyphs are abundant, but nowhere do they exhibit any degree of aesthetic advancement or any approach to a glyphic system. Obsidian, jasper, and chaledony are among the native substances used for chipping arrow- and spear-points, knives, scrapers, and drill-points. Turquoise mined in the Cerrillos near Santa Fe and in other localities in New Mexico, Arizona, and Nevada, was made into various ornaments, including mosaic brooches, pendants, ear-ornaments, hair-combs, and rings, and into beads so finely drilled with the pump-drill that the process of perforating them is a mystery. Axes and hammers both singly and doubly grooved are common throughout the area; arrowshaft straighteners and smoothers are often excellently made; metates and manos of varying degrees of coarseness for grinding corn, and mortars and slabs for pounding and grinding foods and paint are found among the remains of many households. The stone gouge, celt, and chisel, usual to other localities, are absent; but gouges, chisels, awls, punches, spatulas, knives, flakers, weaving implements, and various other tools of bone or of antler are common. Slightly tapering tobacco pipes, usually quite plain, are characteristically Pueblo; others, used as "cloud-blowers," are sometimes perfectly cylindrical. Cane cigarettes have been found in sacrificial caves by thousands. There is no evidence that the people of the arid region possessed any knowledge of metal-working, the copper bells found there being doubtless of Mexican origin.

Burial customs varied more or less with the locality. In some places the remains were deposited in talus, in others cemeteries were provided, and often interment was made beneath the floors of dwellings. In the Gila drainage of Arizona both house burial and cremation were practised, and cremation found its way at least as far as ancient Zuñi. Very frequently the personal belongings of the departed were deposited with his remains, and rich indeed have been the mortuary objects found in some graves.

As in prehistoric times the Pueblo tribes have been reduced in number of villages and in population since they first became known to the Spaniards in 1540; but the linguistic families seem to be the same today as then—Zuñi, Hopi, Tanoan (Tigua, Tewa, Jemez), Keres—and there is no reason to suppose that there was any notable linguistic change for a long time before the beginning of the historic period. In addition to the Pueblos other sedentary Indians still inhabit the arid region—Pima, Papago, Maricopa, and several tribes of the Yuman family within the drainage area of the Colorado river—but these are in no way comparable with the Pueblos. The non-village Indians are the Ute, Paiute, Navaho, and several Apache bands, but there is reason to believe that the Athapascan Navaho and Apache did not enter New Mexico and Arizona until after the Spanish advent.

VII. The California Area.—Despite its diversified physiography and its remarkable number of unrelated languages, ancient California exhibits a uniformly primitive aboriginal culture as indicated by its antiquities, with a few marked exceptions. In most of its eastern and southern desert areas the Indian

inhabitants were doubtless as lowly, on the whole, as were the historic occupants of the region, if we except a wave of very early Pueblo culture, characterized especially by decorated pottery, recently found to have extended across Nevada practically to the California line, and being especially well advanced in southeastern Nevada. Also in western Nevada cave explorations have yielded prehistoric remains of Indians whose chief subsistence was gained from wild plants, rabbits and other small mammals, fish, and ducks, and possibly from a very limited agriculture. They made basketry, textiles, feather head-dresses, simple implements of wood, stone, and bone, as well as cordage, fish-hooks, fish-nets, rabbit-snares, and decoy ducks on a tule foundation. The abundance of baskets made of coiled osiers and elaborately decorated, the presence of the atlatl and the absence of pottery, all suggest an extension of the Basket-maker culture of the Pueblo region. There are parts of California which give indication of specific localized sub-cultures, as in the Humboldt Bay district, where an animal-shape stone club having affiliations in Oregon and on Columbia river is found. In lower San Joaquin valley have been unearthed narrow cylindrical vases of steatite, plain and incised earthenware balls, small crescentic obsidian blades such as are known to have been used by the Miwok in dances to represent bear's claws, and thin effigy ornaments of haliotis and mussel shell. Near Buena Vista lake at the head of San Joaquin valley, in the historic Yokuts territory, associated with prehistoric burials were recovered (a) an eagle's skull with eyes of haliotis, indicating Yokuts origin in connection with an eagle-mourning ceremony and therefore suggesting connection with an eagle-killing ceremony of the Luiseno and Diegueño of southern California; (b) a similar connection with southern California and the Southwest afforded by a club of the potato-masher type; (c) the hair preserved with some of the Buena Vista Lake skulls pertaining to an individual of the region is plastered in long masses typical of the historic Colorado river tribes and the Pima and Maricopa of Arizona; (d) and of even greater interest as suggesting intrusion is a cotton blanket which unquestionably came from one of the settled Pueblo tribes of New Mexico or Arizona. The sub-culture of the Santa Barbara islands and mainland is characterized by the greatest number of unique forms and specialized types found in California. They are mortuary and probably Chumashan, of unknown age.

California offered every means for agriculture, but its wild vegetal products, especially acorns, berries and seeds, were sufficiently abundant to afford sustenance to the interior tribes without recourse to tillage, consequently it is the only sedentary culture area in the United States where corn was not cultivated. Pottery, sometimes with rudimentary decoration, was made in the southern half of California for domestic and for mortuary uses, but it is in no-wise comparable with that of the Pueblos. Movable mortars (found under ancient conditions only in the northern half of the state), bowls and globular cooking vessels, especially of steatite obtained chiefly from Santa Catalina island, together with a great variety of basketry, some of which has not been excelled anywhere, took the place of pottery to a large extent; these with the pestle, the heavy globular, conical and cylindrical mortars, the later metate slabs with their flattish hand-stones, and the pounding slab used by the coast tribes from San Francisco bay northward, were the only utensils suitable for gathering, preparing, containing and storing the native vegetal products. In the northern part the large mortars consist of excavations in bedrock. Many of the stone vessels are exceptionally well made, and some are ornamented with shell incrustated with bitumen. Rectangular and ovoid cooking plates and tobacco pipes of steatite, and polished bowls and cups of serpentine, are among the stone objects of the higher class from the historic Chumash territory about Santa Barbara. In the central and northern parts, especially in the Hupa country, black and mahogany obsidian is abundant, hence chipped implements of this material are found in great numbers. The large ceremonial knives, or batons, of obsidian, some of which are two feet or more in length, are marvels of the flaking art, and barring the flaked obsidian objects of Mexico are second in this respect only to the slender flint blades of ancient Tennessee. There are also superb flint blades in some localities, and arrow-points and spear-

heads of exceptional beauty. Unusual stone artifacts are circular digging-stick weights, hook-shape carvings, killerwhale images, boat-shape amulets of steatite found in the Santa Barbara region, and the plummet-like stones and imperforate banner-stones of middle California. The grooved stone axe, the celt and the gouge, implements of such high importance in other areas, do not occur or are of great rarity on the Pacific slope, the small adze-blades, and perhaps implements of shell taking their place to some extent. The occurrence of stone artifacts in the auriferous gravels of California has been mentioned in referring to the antiquity of man in America.

Sea-food was abundant and formed the chief diet of the inhabitants of the coast and adjacent islands, as is attested by the abundant shell-heaps, the shells being chiefly mussels, clams and oysters. The heaps about San Francisco bay, some of which, estimated to be at least 3,000 years old and which were still occupied after the coming of the Spaniards, reach enormous proportions, the Ellis Landing heap having a million and a quarter cubic feet of material. The principal artifacts from these mounds are obsidian implements, mortars and pestles, bone awls and plummet-like "charm stones," all substantially with the same frequency throughout. The ease with which shells of all kinds were procured (haliotis, clam and dentalium especially) profoundly influenced the native arts, for some of the shells were used not only as lesser utensils, but afforded the means for incrusting both ornaments and objects of utility, and in the north were made into wampum for trade and for embellishing garments, baskets, etc.

There is no reason to suppose that the dwellings of the California Indians in early times differed materially from those known to history. They were all of a temporary character, being built of thatch, brush or bark, sometimes of poles covered with earth, and in the northern forest country slabs of wood were employed. Stone was not used as building material. The floor of the dwelling was usually excavated lower than the surrounding surface. The absence of ruins and earthworks has made the discovery of inhabited sites largely a matter of accident, yet it is known that the prehistoric sedentary population of California was large. Prehistoric sites rarely reveal anything of moment that is not apparent in the life of the recent natives of the same locality, hence archaeology has added little to the determinations of ethnology.

Notwithstanding the excellence of their basketry, their well-made utensils of stone, their chipped obsidian and flint implements, and their work in shell and bone, the California Indians were far from attaining the degree of material culture reached by the Pueblos of the arid region. From central California northward the status of culture represented by art works rises gradually as we pass to the north through Oregon, Washington and British Columbia, the culmination being reached by the tribes of the north-west coast.

VIII. Columbia-Fraser Area.—This culture region extends from California in the south to the Columbia and Fraser drainage area in the north, including all the area occupied by the historic Shapshian tribes of Washington, Oregon and Idaho, but excluding the strip of coast north of the Columbia. While its culture phenomena are diversified, owing to the differences between the moist, forested environment of the coast and the semi-arid interior, yet in large measure it is uniform. The inland sub-culture grades into that of the plateau and mountain region on the east, due in part to the presence of the bison, a closer proximity to the tribes of the plains, and remoteness from the tribes of British Columbia. The culture of the entire area merges gradually with that of California, but it presents strong contrasts with the culture of the north-west coast.

The historically known tribes of the area belong to a number of distinct linguistic groups who subsisted and to a large extent still subsist by fishing and hunting, and by the natural supply of seeds, nuts, fruits and roots, in the southern part acorns and fish being the principal food, while all along the Columbia river especially salmon was the staple. Their better houses in the coastal region, some of them very large, were of planks with shed or gable roofs, now traceable chiefly by the depressions of their shallow floor excavations; in the interior stone-capped earth rings, 30

feet or more in diameter, mark the sites of pit-houses. In the Nez Percé country, on Snake and Clearwater rivers, village-sites are marked by circular and elongate house-rings varying from 25 feet in diameter to 18 by 60 to 85 feet, represented by a depression a foot to three feet deep, with elevated rims—the remains of ordinary dwellings and of communal lodges. As in California, along the shores are numerous shell-heaps, artifacts from which virtually agree with those of the general region. In Willamette valley and in southwestern Oregon, as well as in Washington, burial mounds have yielded a wide range of ordinary local articles, associated in some cases with objects of civilized origin. Earthworks and simple fortifications are mentioned, but little is known of them. Petroglyphs are distributed throughout the region, those opposite The Dalles, in Washington, showing correlation in technique and design with certain pictographic animal figures in Idaho, Utah and Nevada. Stone artifacts seem to vary little from those known to the historic Indians. Certain forms of implements and other stone objects characteristic of California extend northward throughout the length of the Columbia-Fraser area, while other forms characteristic of the north-west coast extend far to the south. Deep globular mortars prevail in some parts, and metates are found in others. The pestles in certain localities are of the oblong-club shape, many well finished and tastefully carved; in others they are ovoid or flattish, many being merely adapted boulders; and all were occasionally used as hammers. Tobacco pipes, straight in the south and bent in the north, are known; the grooved axe is absent, but adzes, celts and chisels of jadeite have been found on the middle Columbia. Among the other abundant stone objects are dishes, knives, net-sinkers, abraders, scrapers, reamers, drills, etching tools, weaving implements; spindle-whorls, plain and grooved hammers and mauls, bowls, paint cups, arrow-shaft smoothers, clubs, and projectile points; and antler wedges and bone clubs and fishing implements are likewise found.

Exceptional stone objects are large obsidian blades like those of northern California, batons of stone and bone carved in representation of animals, looped weight-like stones, and certain strange carved heads of simian aspect, unlike any other carvings in North America.

Lewis H. Morgan and others regarded the Columbia as having a very important place in the ethnic history of North America: that it was a kind of hothouse, the multiplying peoples of which spread out over the south and east; but no linguistic or other evidence has been adduced in support of this contention.

IX. North-west Coast Area.—As defined by Holmes, this archaeological culture classification area comprises a rather narrow strip of the mainland and the contiguous coastwise islands in British Columbia and Alaska, and extends from Puget Sound northward to Mount St. Elias, a distance of twelve or thirteen hundred miles. The tribes occupying this region as known to history belong to several linguistic stocks. Their material culture embodies many noteworthy features which cause it to stand well apart from all other cultures of the continent, yet it resembles in some respects the material culture of the coast on the south and of the inland to the east. Hunting and especially fishing have always been the chief sources of food, agriculture being unknown. Their territory abounding in splendid forests, the inhabitants developed great skill in woodworking with stone implements, which of course were superseded by tools of metal on the advent of the whites in the 18th century. The dugout canoes, made from trunks of the giant cedar and sometimes nearly a hundred feet long, are marvels of beauty and grace of line, and are probably the world's highest achievement in this direction. Their houses were often built of immense hewn timbers, and their carved and painted totem poles, house and grave posts, storage chests, human and animal effigies, and many and varied feast and other vessels, utensils, masks, etc., are worthy of the art of any people. While the sculptures of these people have doubtless been accelerated by the acquirement of steel tools, their innate aesthetic ability is shown by their minor works of art in stone, shell, ivory, antler, bone, horn and copper, many of which exceed the more massive productions in beauty and refinement. The smaller objects of stone include hammers and mauls of the highest known types,

adzes, mortars, pestles, knives, chisels, clubs, batons, pipes, amulets and ornaments, jade being greatly sought and often laboriously fashioned to suit individual needs. Chipped stone objects are rare; pottery is unknown, vessels of wood, bone and horn serving instead. Ornaments and utilitarian articles of bone, ivory, wood and stone were attractively inlaid with iridescent shell. The ancient character of the graphic art of the north-west coast people is suggested by the petroglyphs, numerous in some parts, which display the same peculiar characteristics as the painting, engraving and weaving of the historic peoples. Copper has long been worked, and with considerable skill, especially into masks, rattles, whistles, knives and other utensils, ornaments and certain shield-like objects which are highly esteemed as symbols of wealth; but it is not known whether the copper art was an activity of prehistoric times, although the native metal occurs in surface deposits in the region. Altogether features of the arts of the north-west coast are thought to suggest inspiration from the Pacific islands; but this has not been shown to be the case, although it has been pointed out that if any such influence existed, it may have been exerted exclusively during the long period since modern seagoing vessels began to ply back and forth on the Pacific. Traces of advanced Asiatic art occasionally encountered along the coast are attributable to the stranding of vessels carried oversea by the Japan current rather than to purposeful voyagings in early times.

The peculiar geography of the country, in conjunction with its exceptional vegetable and animal resources, doubtless served to develop the unusual culture of this people. Archaeological research in the region has not been carried far enough to show that the forms of native artifacts are distinct from those that appear to have been in use in historic times, but so far as observation has been possible the culture is a homogeneous one, with only slight trace of antecedent forms of art either lower or higher than the historic. Nothing has been observed in the culture of the people suggesting migrations from the north by way of Bering strait, and no characteristic features that might have arisen within the local environment or from possible intrusions within a few centuries.

X. Arctic Coast Area.—As its name indicates, this culture area extends from Greenland on the east to farthest Alaska and even to northeastern Siberia on the west, and from the tortuous shores of the continent somewhat indefinitely into the interior to the range of the northern Algonkin and Athabaskan tribes, into whose culture that of the Arctic Eskimo merges. Where not affected by the culture of these bordering Indians, that of the Arctic Coast area is essentially Eskimoan in both its prehistoric and its historic phases, and the uniformity of the environment and of the physical character of the inhabitants has resulted in marked uniformity in arts and customs. Archaeological research has been conducted at only a few sites on the Atlantic and Pacific coasts, but these have revealed little in the way of domiciliary and mortuary remains or of artifacts that are not practically identical with the types still in use where the natives remain free from the influences of civilization. Yet in some instances the archaeological remains, palpably Eskimoan, are regarded by the natives of today as relics of mythological beings.

In the frigid Eskimo habitat shelter was ever a necessity. The dwellings were built in such manner as was most convenient, and of such materials as were available. Driftwood, whalebones, stone, earth, sod and snow were utilized as occasion demanded, and the sunken floors and extended passages of the more permanent houses helped to afford a degree of comfort during the long and rigorous winters. Traces of such houses, and of storehouses and cairns, have been noted by explorers for thousands of miles along the frozen shores. Fire for cooking and for bodily comfort within the houses was obtained by the use of a flat earthenware or stone (usually steatite) lamp, with oil or fat for fuel—the only device of its kind known to aboriginal America. Food was obtained solely by hunting and fishing, and the implements and other devices used in these activities are not only highly ingenious, but many of them, especially those of ivory and bone, are beautifully carved and engraved, although such ornamentation is believed to be of relatively modern origin. In the western part of the Eskimo range, jade, pectolite, and other hard varieties of stone were

fashioned into mortars, pestles, dishes and other receptacles, hammers, adzes, chisels, picks, knives, whetstones, sinkers and various other necessary appliances, and hard and brittle stones, such as slate and flint, suitable for fracturing, were wrought into knives, scrapers, drills and projectile points; yet, although the Arctic dwellers were skilled in the flaking and chipping processes, their spear and harpoon points, knives, and especially the woman's knife, or *ulu*, were often shaped and sharpened by grinding, a process probably suggested by its employment in working ivory and bone. The grooved axe, celt and gouge are absent, evidently because there was relatively little occasion for fashioning wood of considerable size. Stones of many varieties were used also for manufacturing articles of personal adornment,—labrets, ear-plugs, beads, pendants,—some of these being unsurpassed for beauty of material and finish. Figurines, toys, fetishes, charms, talismans and a multitude of other small objects were likewise carved with great skill and of all available materials. Rather heavy pottery vessels have been found especially along the coast as far east as Franklin bay; they are of good form, of medium or large size, and are ornamented with incised and impressed decoration. The age of these vessels is not known, but evidently the potter's art has long been obsolete except for the manufacture of lamps where stone was not available. The shell-heaps of the Alaska coast are numerous, but are chiefly remarkable as representing three successive periods of occupancy—the littoral period, characterized by the absence of artifacts; the fishing period, in which there are traits of very primitive forms of stone implements; and the hunting period with evidences of culture approaching that of the historic Alaskan tribes—estimated altogether to represent an approximate period of 3,000 years, or about equal in age to the larger shell-heaps of California.

As known to ethnology, the Eskimo (and there is no reason to suppose that the ancient remains found on the Arctic shores of America are not assignable to Eskimo culture), considering their harsh environment, the ever-present difficulties involved in the food quest, and the limited range of materials available for their purposes, achieved a high degree of culture, as attested by the ingenuity of the appliances necessary to their daily life as hunters and fishermen which often involved long journeys by canoe, the facility with which they could build comfortable houses with what little their country afforded, and the expression which they gave to their aesthetic sense in almost everything they manufactured.

XI. The Northern Interior Area.—Since known to history this vast region has been occupied by Athabascan and Algonkin tribes who subsisted almost entirely by the chase, moose and caribou being the larger quarry, while a host of mammals of lesser species were also pursued or trapped for food or to provide skins for clothing and shelter. With few exceptions their material culture was poor, hence the archaeologist may hardly expect to find more than such commonplace articles as projectile points, knives, scrapers, abrading stones, hammerstones, etc., used by a hunter people, or to add to the meagre information that on the southern border the cultures are marginal to those of the adjoining area. Archaeologically the area is practically a terra incognita, yet it may hold much of interest in the elucidation of the questions of migration of the ancestors of the Indians from northeastern Asia, and of the separation of Athabascan bands in this far northern land and their gradual movement into northern California and to the arid southwest. Attention has been called by Holmes to the probability that all traces of very early occupancy, if such there were, must have been wiped out by the ice sheets which, one after another, must have swept southward over the country, "the latest invasion in the central region continuing down to the period which witnessed the building of the Egyptian pyramids." Limited areas in the west and north-west were not thus invaded by the ice, but as yet these have not yielded anything of particular archaeological value.

(F. W. H.)

BIBLIOGRAPHY.—A list of the more important published writings on the subject would number many hundreds of titles, therefore only a few may be mentioned here. Fortunately, however, some of the works noted contain bibliographies which serve as a means of opening to the reader a full view of American Archaeology and its problems. Of special usefulness in this direction are: W. H. Holmes, *Handbook of*

Aboriginal Antiquities, Bull. 60, Bur. Amer. Ethnol., Washington, 1919; Clark Wissler, *The American Indian*, New York (Oxford Univ. Press), 1922; F. W. Hodge, ed., *Handbook of American Indians*, Bull. 30, Bur. Amer. Ethnol., Washington, 1907-10. For the treatment of the various culture areas and of specific subjects pertaining thereto in serial publications, consult: (1) *Annual Reports* and (2) *Bulletins of the Bureau of American Ethnology*, Washington; (1) *Annual Reports*, (2) *Bulletins* and (3) *Proceedings of the U.S. National Museum*, Washington; (1) *Annual Reports*, (2) *Contributions* and (3) *Miscellaneous Collections of the Smithsonian Institution*, Washington; *Contributions to North American Ethnology* (U.S. Geogr. and Geol. Surv. of the Rocky Mtn. Region), vols. i-viii, ix., Washington, 1877-93; (1) *Bulletins*, (2) *Memoirs* (especially for Northwest Coast archaeology), (3) *Anthropological Papers* and (4) *Natural History*, published by the American Museum of Natural History, New York; (1) *Annual Reports* and (2) *Papers of the Peabody Museum of American Archaeology and Ethnology*, Cambridge, Mass.; (1) *Contributions*, (2) *Indian Notes and Monographs*, (3) *Indian Notes* and (4) *Leaflets of the Museum of the American Indian*, New York; *Anthropological Series of the Field Museum of Natural History*, Chicago; *Bulletins of the New York State Museum*, Albany; *University of California Publications in American Archaeology and Ethnology*, Berkeley; *Proceedings of the American Antiquarian Society*, Worcester, Mass.; *Proceedings of the Davenport Academy of Science*, Davenport, Iowa; *Proceedings and Collections of the Wyoming Historical and Geological Society*, Wilkes-Barre, Pa.; *Bulletins of the School of American Research*, Santa Fe, New Mexico; "El Palacio," Museum of New Mexico, Santa Fe; "Arrowpoints," Alabama Anthropological Association, Montgomery; (1) *Year Book* and (2) *Bulletin of the Milwaukee Public Museum*; *Bulletin of the University Museum*, Philadelphia; *Bulletin of the Department of Archaeology*, Phillips Academy, Andover, Mass.; *American Anthropologist*, vols. i-xi., Washington, 1888-98, and n.s., vols. i-xxx., New York and elsewhere, 1899-1928; *American Antiquarian*, vols. i-xxxiii., Chicago and elsewhere, 1878-1910; (1) *Ohio Archaeological and Historical Quarterly*, (2) *Publications in Archaeology*, Ohio Archaeological and Historical Society, Columbus; *Wisconsin Archaeologist*, Madison; *Annual Archaeological Reports* (Canadian Institute and Minister of Education), Toronto, 1888-1925 (for bibliography see the 9th Report, 1897); *Memoirs Department of Mines*, Geological Survey of Canada, Ottawa; *Bulletins of the Victoria Memorial Museum* (Anthr. Press), 1924 (with bibliography of the Pueblo region); Therkel Mathiasen, *Archaeology of the Central Eskimos*, Copenhagen, 1927.

NORTHAMPTON, EARLS AND MARQUESSES OF.

The Northampton title has been held in various English families. About 1080 Simon de Senlis (d. 1109), a Norman noble, and the builder of Northampton castle, was created earl of Northampton as well as earl of Huntingdon by William the Conqueror; his son Simon (d. 1153) was also recognized in the title about 1141, though his stepfather, David, king of Scotland (1084-1153), had meanwhile obtained the earldom in right of his wife. The second Simon died childless. In 1337 William de Bohun (c. 1310-60), a son of Humphrey de Bohun, 4th earl of Hereford and 3rd earl of Essex, was created earl of Northampton; and his son Humphrey, who succeeded, fell heir in 1361 to the earldoms of Hereford and Essex, which thus became united under that of Hereford. The titles, however, became extinct at his death in 1372.

In 1547 William Parr (1513-71), son of Sir Thomas Parr and brother of Catherine Parr, queen of Henry VIII., was created marquess of Northampton, and though attainted in 1553 was recreated marquess in 1559. He favoured the claim of Lady Jane Grey to the English throne. Although sentenced to death he was pardoned and released from prison at the end of 1553. North-

ampton died at Warwick on Oct. 28, 1571. He left no children and his marquessate became extinct. In 1604 Henry Howard (*see below*) was created earl of Northampton, his title dying with him. It next passed into the Compton family, where it has since remained. The 1st earl of Northampton in this line, William Compton (d. 1630), who received the title in 1618, was a great-grandson of the Sir William Compton (1482-1528) who was with Henry VIII. at the Field of the Cloth of Gold, and his son the 2nd earl is noticed below. The 9th earl, Charles Compton (1760-1828), was created a marquess in 1812, receiving at the same time the titles of Earl Compton and Baron Wilmington.

HENRY HOWARD, earl of Northampton (1540-1614), was the second son of Henry Howard, earl of Surrey, the poet, and of Lady Frances Vere, daughter of the 15th earl of Oxford, and younger brother of Thomas Howard, 4th duke of Norfolk. After discovery of his brother's plot to marry Mary, Queen of Scots, and of his own correspondence with her, he was arrested more than once on suspicion of harbouring treasonable designs. In 1583 he published a work entitled *A Defensive against the Poysen of supposed Prophecies*, an ostensible attack upon astrology, which, being declared to contain heresies and treason, led to his imprisonment for a short time. After the accession of James I. he received many honours, and became Lord Privy Seal (1604) and a commissioner of the treasury (1612). He was one of the judges at the trials of Raleigh and Lord Cobham in 1603, of Guy Fawkes in 1605, and of Garnet in 1606, in each case pressing for a conviction. In 1604 he was one of the commissioners who composed the treaty of peace with Spain, and from that date he received from the Spanish Court a pension of £1,000. Northampton died on June 15, 1614. His title died with him. Northampton built Northumberland house in London and superintended the construction of the fine house of Audley End. He founded and planned several hospitals. Bacon included three of his sayings in his "Apophthegms," and chose him as "the learnedest councillor" in the kingdom to present to the king his *Advancement of Learning*.

Northampton's works are: a *Treatise of Natural and Moral Philosophy* (1569; ms. in the Bodleian library); a pamphlet supporting the union between Elizabeth and the duke of Anjou (1580; Harleian mss. 180); *A Defensive against the Poysen of supposed Prophecies* (1581); a reply to a pamphlet denouncing female government (1589; Harleian ms. 7021); *Duello Foiled*, printed in T. Hearne's *Collection of Curious Discourses* (1775), and ascribed there to Sir Edward Coke; *Translation of Charles V.'s Last Advice to Philip II.*, dedicated with a long epistle to the queen (Harl. 836, 1506 and elsewhere in Stowe 95, King's mss. 106); devotional writings (Arundel mss. 300); speeches at the trials of Guy Fawkes and Garnet in *State Trials*, vol. i. In Somers Tracts (ed. 1809), ii. 136, his opinions on the union between England and Scotland are recorded.

See the life in Surrey's and Wyatt's Poems, ed. by G. F. Nott (1815), and Sidney Lee's article in the *Dict. Nat. Biog.*

SPENCER COMPTON; 2nd earl of Northampton in the Compton line (1601-43), was the son of William, 1st earl, lord president of the marches. On the outbreak of the Civil War he was entrusted with the execution of the commission of array in Warwickshire. After varying success and failure in the Midlands he fought at Edgehill, and after the king's return to Oxford was given, in November 1642, the military supervision of Banbury and the neighbouring country. He was attacked in Banbury by the parliamentary forces on Dec. 22, but relieved by Prince Rupert the next day. In March 1643 he marched from Banbury to relieve Lichfield, and having failed there proceeded to Stafford, which he occupied. Thence on March 19, accompanied by three of his sons, he marched out with his troops and engaged Sir John Gell and Sir William Brereton at Hopton Heath. In the moment of victory he was surrounded by the enemy, and, refusing quarter, was slain.

See the article in the Dict. of Nat. Biog. by C. H. Firth; E. B. G. Warburton, *Life of Prince Rupert*; S. R. Gardiner, *Hist. of England and of the Civil War*; *Thomson Tracts*, E 99 (18) (Hopton Heath and Northampton's death), E 103 (11) (elegy), E 111 (11), E 110 (8) 1642 (Proceedings at Banbury), E 83 (47) (speech).

NORTHAMPTON, county town of Northamptonshire, England, 66 m. N.W. by N. from London by L.M.S.R. Pop. (1921) 90,895.

British and Roman remains have been discovered near Northampton and it became the chief settlement of the Angle tribes early in the 6th century. It was occupied by the Danes in the reign of Edward the Elder. The mayor was the chief officer in the 13th century, and Henry VI. granted the incorporation charter in 1460. Tanning was an industry in the time of Edward I. and in 1675 a law was made forbidding strangers to purchase hides in the town except on fair-days. Boots and shoes were made here in the reigns of John and Edward I., and by the 17th century Northampton was one of the most noted places in England for their manufacture.

Northampton has been the meeting-place of several important councils and parliaments. In the wars between John and his barons the castle withstood a siege by the latter, but in 1264 it was occupied by the barons under the earl of Leicester. In the Wars of the Roses it was the scene of the battle in which Henry VI. was defeated and taken prisoner in 1460. During the Civil Wars of the 17th century it was held for the parliament by Lord Brooke. In 1675, 600 houses were destroyed by fire.

The town is situated on the river Nene. The main roads converging upon the town meet near the centre in a market-place. All Saints church was rebuilt after the fire of 1675, but retains its Decorated embattled tower. The church of St. Giles, a cruciform structure in the 12th century, has been greatly changed, and besides a Norman doorway contains Early English, Decorated and Perpendicular work. St. Peter's is supposed to be of the same date and its interior is Norman. St. Sepulchre's, one of the four round churches remaining in England, may have been built by the Knights Templars at the close of the 11th century.

Northampton is the seat of a Roman Catholic bishop, and there is a pro-cathedral. Near the town there were a Cluniac priory of St. Andrew, a house (Delapr ) for nuns of the same order, and one for Augustinian canons; but the first has disappeared, the site of the second is occupied by a modern mansion, and of the third there are only slight fragments. Some portions of the castle were re-erected on a new site after their destruction when the Castle station was built by the L.M.S. Company. In Hardingsstone, south of the town, is one of the original Eleanor crosses. The free grammar school was founded in 1552. The charitable foundations include St. John's hospital (12th century) and St. Thomas's hospital, founded in 1450 in honour of Thomas   Becket. There is a race-course north of the town. The staple trade is the manufacture of boots and shoes. There are also currying, tanning and textile works, breweries, iron foundries and brick works. The cattle market is extensive.

NORTHAMPTON, a city of Massachusetts, U.S.A., the county seat of Hampshire county; on the Connecticut river and Federal highway 5, 16 m. N. of Springfield. It is served by the Boston and Maine and the New York, New Haven and Hartford railways. Pop. (1920) 21,951 (23% foreign-born white). Venerable trees, an irregular plan, and the grounds of the several institutions make the city very attractive. It is the seat of Smith college (*q.v.*), two preparatory schools for girls, a State hospital for the insane, the Clarke School for the Deaf (1867), and Smith's Agricultural school, founded by bequest of Oliver Smith (1766-1845), but opened only in 1908. Mt. Holyoke (954 ft.) is 2 m. S.E. Within the city (on the Mill river) are the villages of Florence and Leeds, important manufacturing centres. The city's factory output (largely sewing silk, silks and satins, silk hosiery, cutlery and brushes) was valued in 1925 at \$16,056,674. Northampton was settled in 1654, became a separate town in 1656, and was incorporated as a city in 1883. It was the birthplace of Caleb Strong, Joseph Hawley, Timothy Dwight, William D. Whitney and Arthur, Benjamin and Lewis Tappan. Jonathan Edwards was pastor here from 1727 to 1750.

NORTHAMPTON, a borough of Northampton county, Pennsylvania, U.S.A., on the Lehigh river, 6 m. N.W. of Allentown; served by the Central railroad of New Jersey. Pop. 9,349 in 1920 (29% foreign-born white); estimated locally at 10,000 in 1928. It is a cement-manufacturing centre, and there are silk mills and iron works in the vicinity. The borough was settled about 1740 and incorporated in 1901.

NORTHAMPTON, ASSIZE OF, a short code of English laws issued in 1176, drawn up in the form of instructions to six committees of three judges each, who were to visit the six circuits into which England was divided for the purpose. Though purporting to be a reissue of the Assize of Clarendon (1166), it contains in fact many new provisions. As compared with the earlier assize it prescribes greater severity of punishment for criminal offences; arson and forgery were henceforth to be crimes about which the jurors were to enquire, and those who failed at the ordeal were to lose a hand as well as a foot. In what is perhaps the most important section we may probably see the origin of the possessory action of *mort d'ancestor*, an innovation scarcely less striking than the institution of the *novel disseisin* in the winter of 1166. The justices were also ordered to try proprietary actions commenced by the king's writ for the recovery of land held by the service of half a knight's fee or less. In their fiscal capacity they were to enquire into escheats, churches, lands, and women in the king's gift. The royal bailiffs were to answer at the exchequer for rents of assize and all the perquisites which they made in their offices, and apparently the duty of enforcing this provision was entrusted to the justices. As a result of the rebellion of 1173-74 it was provided that an oath of fealty should be taken by all, "to wit, barons, knights, freeholders, and even villeins (*rustici*)," and that any one who refused should be arrested as the king's enemy, and the justices were to see that the castles, the demolition of which had been ordered, were razed.

See Pollock and Maitland, *History of English Law* (1898); Stubbs, *Constitutional History of England* (1895). The text occurs in *Cronica Rogeri de Howden* (Rolls Series), ii. 89, and *Gesta Henrici Regis Secundi* (Rolls Series), i. 108. It has been reprinted from the latter by Stubbs in *Select Charters* (1913). (G. J. T.)

NORTHAMPTONSHIRE, an east midland county of England, bounded north by Lincolnshire, north-west by Rutland and Leicestershire, west by Warwickshire, south-west and south by Oxfordshire, south-east by Buckinghamshire, and east by Bedfordshire, Huntingdonshire and Cambridgeshire. The area is 1,003.1 sq. miles.

Geology and Physical Features.—The underlying structure of the county is very simple. It forms part of the Jurassic escarpment, here known as the Northampton uplands. All the rocks are of Jurassic age, the dip being in a general way to the south-east, and the strike from south-west to north-east. The oldest, and most westerly belt consists of Lias formations which cover a large surface in the south-west and centre, around Banbury, Daventry and Market Harborough, and they are also exposed along the rivers near Towcester, Northampton, Wellingborough and Kettering. The marlstones of the Middle Lias were formerly much used for building material; the Upper Lias is worked for bricks at Easton Neston (Towcester), Blisworth, Gayton, Heyford, Northampton, Wellingborough, Rushden, Irthlingborough, Kettering and Corby. Through the middle of the county, north-east to Northampton, Rockingham and Peterborough, is an elevated tract of Oolitic rocks, which formerly supplied stone, of which many of the villages are built, as well as lime and marl. The New Duston quarries have several varieties of good stone, the district around Northampton a limestone known as Pendle, and Weldon (Lincolnshire Oolite) a noted freestone; Barnack Rag (near Stamford) is no longer worked. The great Oolite limestone, though unsuitable for building material, owing to the ease with which it weathers, was largely used in the past, Culworth, Blisworth and Cosgrove quarries being famous. At the base of the Inferior Oolite, Northampton sands yield iron ore, which is worked at Duston, Culworth, Towcester and at numerous localities north-east of Northampton. Certain hard shelly beds in the Oolite rocks have been polished and used as marble.

On the south-east border of the county, a belt of Oxford clay occupies the surface, good exposures occurring in the brick fields about Peterborough. Boulder clay is widely distributed over the uplands and in the east of the county, and glacial and river gravels are also plentiful. The south-west portion of the county forms the principal watershed of the Midlands; the Cherwell, the Avon, the Leam, the Welland, the Nene have their sources in this region, and all form sections of county boundaries. The position of Dav-

entry as a wireless station and a meeting place of roads is also related to this fact of centrality and elevation. The longitudinal river Nene flows in a north-easterly direction along the foot of the uplands, draining them to the Wash.

History and Early Settlement.—In primitive times the waters of the North sea reached almost to the foot of the Northamptonshire uplands. The immigrants of the end of the Stone age seem to have penetrated up from the coast, and Peterborough has yielded important finds of early pottery. Some Beaker pottery occurs, chiefly on the uplands. There are a few material objects of the La Tène I. culture and the La Tène III. culture. During the Iron age, the uplands offered defensible sites, and many hill camps were made, Hunsbury (1½ m. S.W. of Northampton), being one of the most famous. In Roman times, iron, stone and clay were worked, and Towcester was an important station on the Watling street route to the north-west. At some time in the 7th century the district suffered a simultaneous invasion (West Saxons from the south, Anglian tribes from the north), finds show a mingling of races, but West Saxon influence never spread farther north than a line from Daventry to Warwick, and with the extension of the Mercian kingdom under Penda and the conversion of the midland districts, ceased altogether. The abbey at Medehamstede (now Peterborough) was begun by Penda's son, Peada, in 655, and about the same time foundations were established at Peakirk, Weedon Beck, Castor and Oundle. In 870 the district was overrun by the Danes, and Northampton was one of the five Danish boroughs, until in 921 it was recovered by Edward the Elder, who fortified Towcester in that year.

In the 11th century Northamptonshire was included in Tostig's northern earldom; but in 1065, together with Huntingdonshire, it was detached from Northumbria and bestowed on Waltheof. The monastic foundation of Peterborough survived the Conquest. Norman castles existed at Rockingham, Barnwell, Lilbourne and Northampton. The shire is probably of Danish origin, representing in the 10th century the area which owed allegiance to Northampton as a political and administrative centre. In 921 this area extended to the Welland, and at the time of the Domesday survey the boundaries were approximately those of the present day. Northamptonshire is first mentioned by name in the *Historia Eliensis*, in connection with events which occurred at the close of the 10th century.

The Geld roll (William I.) and Domesday (1086) mention 28 hundreds in Northamptonshire, and part of Rutland is assessed under this county. By 1316 the divisions were changed, re-named and reduced to 20, and have remained practically unaltered. The names of the hundreds point to primitive meeting-places gradually superseded by villages and towns, and the court for Fawsley hundred met under a large beech tree in Fawsley park until the beginning of the 18th century, when it was transferred to Everdon. The shire-court originally met at Northampton.

Northamptonshire was originally included in the diocese of Lincoln. The archdeaconry of Northampton is mentioned in the 12th century, and in 1291 included the deaneries of Peterborough, Northampton, Brackley, Oundle, Higham, Daventry, Preston, Weldon, Rothwell and Haddon. The diocese of Peterborough was created in 1541, and in 1875 the archdeaconry of Oakham was formed and included in this county the first and second deaneries of Peterborough and the deaneries of Oundle, Weldon and Higham Ferrers.

At the time of the Domesday survey the chief lay-tenant in Northamptonshire was Robert, earl of Mortain, whose fief escheated to the Crown in 1106. The estates of William Peverel, founder of the abbey of St. James at Northampton, also escheated to the Crown in the 12th century. Holdenby House was built by Sir Christopher Hatton, privy councillor to Queen Elizabeth, and Yardley Hastings was named from the Hastings, formerly earls of Pembroke. Higham Ferrers was the seat of the Ferrers family; Braybrook Castle was built by Robert de Braybrook, a favourite of King John; and Burghley House gave the title of baron to William Cecil. During the middle ages the Nene was a busy artery of trade, and many moated homesteads were built on its banks.

Northampton was a favourite meeting-place of the councils and parliaments of the Norman and Plantagenet kings. In 1215 John was besieged in Northampton Castle by the barons, and in 1264 Henry III. captured the castle from the younger Simon de Montfort. During the Wars of the Roses Henry VI. was defeated at Northampton in 1460. In the Civil War of the 17th century the county declared almost unanimously for the parliament. A royalist garrison was placed at Towcester by Prince Rupert in 1644, but almost immediately withdrawn.

In 1547 Brackley and Peterborough returned each two members, and in 1557 Higham Ferrers returned one member. Under the act of 1832 the county returned four members in two divisions, the above boroughs being merged in the county divisions. There are now four divisions with one member each, in addition to a member for the county division.

Architecture.—Of monastic foundations, the abbey-church of Peterborough, afterwards the cathedral, is the only remaining one of importance. At Geddington, and also at Hardingstone, near Northampton, there is an Eleanor cross, erected by Edward I. The county is famous for its churches with beautiful broached spires. To the Saxon period belong the tower of Earls Barton church, on what is probably the mound of an old English strong-house; the tower, etc., at Brigstock; the ground plan, etc., at Wittering; the remarkable tower at Barnack; and Brixworth church, by some believed to include part of a Roman basilica. Of Norman work, excluding Peterborough cathedral, the finest examples are St. Peter's and St. Sepulchre's, Northampton, and the tower of Castor church. St. Mary's church, Higham Ferrers, formerly collegiate, Early English and Decorated, is one of the finest churches in the county; the churches at Irthlingborough and Lowick, with their lantern towers, Warmington, fine Early English work, Rushden, Finedon, Raunds and Fotheringhay should be mentioned.

A gateway at Rockingham, and earth-works at Higham Ferrers and Brackley are worthy of mention. Some castellated ruins remain of the castle at Fotheringhay, famous as the scene of the imprisonment, trial and execution of Mary, Queen of Scots. Barnwell castle, founded by William the Conqueror, is still a fine ruin, which includes four of the round towers and an imposing gateway. Holdenby manor house, where Sir Christopher Hatton (1540–1591) was born, and whence Charles I. was carried away by Cornet Joyce, is largely restored. Among ancient mansions are Castle Ashby, the seat of the Comptons; Althorp, the seat of the Spencers; Drayton House; Burghley House, Stamford, founded by Lord Burleigh (1553); and Kirby Hall, a beautiful Elizabethan building once the residence of Sir Christopher Hatton.

Climate and Agriculture.—The climate of Northamptonshire is mild, and it is drier than many other inland districts owing to its low elevation (rarely more than 700 ft.). The mean annual rainfall at Wellingborough is 27.2 inches. The soil is fertile, nearly nine-tenths of the surface being under cultivation. The Lias clay belt gives rise to good grazing, and 360,134 ac.—nearly three-fifths (1926)—were under permanent pasture. Large numbers of cattle (139,507 in 1926) are fattened, droves from Scotland, Ireland, Wales, Hereford being sent for that purpose. The selling of fat cattle for Christmas markets, sets the population free in winter for hunting, giving rise in the 18th century to the making of whips at Daventry, while the long winter evenings encouraged the use of the tobacco-pipe, made almost exclusively from Northampton clays. Easy access to hides and to bark for tanning in the forests originated an industry in leather, which flourished in Norman times, and, in the middle of the 17th century Northampton began to specialize in the manufacture of boots and shoes, for which it has become famous. The difference in bulk between imported raw hides and exported finished boots and shoes creates an economic problem in connection with this trade. Good wheat can be grown on the boulder clay, but no less than one-sixth of the county is under grain. Beans form an important crop; root-crops are also grown; sugar-beet is a fast developing industry (1,077 ac. in 1926, as against 141 ac. in 1925).

Sheep are kept in large numbers on the rich pastures, improved Leicesters for wool and Southdown for mutton. Wool was important in Norman times; in the 17th century the centre of

weaving changed from Northampton to Kettering. Charcoal-burning was an early industry in the forests (Rockingham, etc.), mast from the oaks also feeding large numbers of pigs; these are still important. Paper-making, dependent on pure water, was introduced in the 18th century; early in the 19th, silk-weaving spread from Coventry.

Communications.—Two main lines of the L.M. and S. railway cross the county, linking London with the industrial north-west. The first is the Wolverton (Bucks) Blisworth, Rugby (Warwick) line, with an alternative route to Northampton, and branches north-east to Peterborough and north to Market Harborough (Leics.); with it are connected at Blisworth junction, branch lines through Towcester, west to Stratford-on-Avon (Warwick) and south-west to Banbury (Oxon). The second is the Wellingborough, Kettering, Market Harborough line with a branch to Oakham (Rutland). There are other branch lines. A main line of the L. and N.E. railway passing through the south of the county, connects with the G.W. railway at Banbury through Woodford. The Grand Junction canal, which is connected with the Oxford canal, enters the county at Braunston on the borders of Warwickshire, and passes by Daventry and Blisworth into Buckinghamshire, a branch connecting it with Northampton. The Grand Union canal unites with the Grand Junction near Daventry, and runs north until it joins the Leicester canal at Foxton, branches passing to Welford and Market Harborough.

Population and Administration.—The area of the whole county is 638,612 ac.; this total includes the soke of Peterborough, which is itself an administrative county, area 53,464 ac. Pop. (1921) 349,363, or without the soke 302,404. In Domesday the county is mentioned as containing 30 hundreds, but it then included a considerable part of Rutland. These divisions were first reduced to 28, and in the Reign of Henry II. to 20, their present number. The administrative counties include four municipal boroughs, namely, Brackley, Daventry, Higham Ferrers and Peterborough, together with the municipal and county borough of Northampton (87,021). There are one court of quarter sessions and nine petty sessional divisions. The borough of Northampton and the liberty of the soke of Peterborough have each a separate court of quarter sessions and a separate commission of the peace. The total number of civil parishes is 346, of which 33 are in the soke of Peterborough. The ancient county contains 297 entire ecclesiastical parishes or districts, wholly or in part, most of them being in the diocese of Peterborough; but small parts of the county fall within the dioceses of Oxford, Ely and Worcester. For parliamentary purposes the county is divided into four divisions, Daventry, Kettering, Peterborough and Wellingborough. The parliamentary borough of Northampton returns one member.

See *Victoria County History, Northamptonshire*; John Norden, *Speculi Britanniae, pars altera, or A Delineation of Northamptonshire* (1720); John Bridges, *History and Antiquities of Northamptonshire*, compiled by Rev. Peter Whalley (2 vols., Oxford, 1791); Francis Whellan, *History, Topography and Directory of Northamptonshire* (2nd ed., London, 1874).

NORTH ANDOVER, a manufacturing town of Essex county, Massachusetts, U.S.A., on the Merrimack river, 2 m. E. of Lawrence; served by the Boston and Maine railroad. Pop. 6,265 in 1920 (30% foreign-born white); 1928 local estimate 7,400. The town was settled about 1643, and a house built in 1667 by Simon Bradstreet, one of the founders, is still standing. His wife, Anne Dudley Bradstreet (1612–72), was the first woman in America to make a reputation as a poet. North Andover was set off from Andover and incorporated as a town in 1855.

NORTH BAY, a lumber, mining and railway town on the north-east shore of Lake Nipissing, northern Ontario, Canada, 227 m. N. of Toronto, on the Canadian Pacific, Canadian National, and Temiskaming and Northern railways. It is the base of supply for the mining districts of Cobalt, Gowganda and Porcupine, and is also noted as a tourist centre and summer resort. Pop. (1921), 10,692.

NORTH BERWICK, royal burgh, parish, East Lothian, Scotland. Pop. (1921) 4,524. It is situated on the south shore of the entrance to the Firth of Forth, 2½ m. E.N.E. of Edinburgh by the L.N.E. railway, being the terminus of a branch line

from Drem Junction. It was created a royal burgh by Robert III. (d. 1406), and though once a port of some importance it dwindled to a fishing hamlet. It is now, however, a fashionable watering-place, frequented for bathing and golf. Near the station are the ruins of the abbey of Cistercian nuns founded by David I. Immediately to the south rises the fine cone of North Berwick Law.

NORTH BRADDOCK, a borough of Allegheny county, Pennsylvania, U.S.A., 10 m. S.E. of Pittsburgh, on the hills back of Braddock and Rankin. Pop. 14,928 in 1920 (27% foreign-born white); estimated locally at 17,000 in 1928. The three boroughs form one community and industrial centre, with large steel works and other important manufactures. North Braddock is chiefly a residential section, but one of the largest steel plants is within its limits. Its assessed valuation for 1927 was \$16,951,535, and the total for the three boroughs was \$42,316,765. The first white man's cabin west of the Alleghenies was built here in 1742 by John Frazier. On the ground now occupied by Braddock and North Braddock was fought (July 9, 1755) the battle in which Braddock was defeated.

NORTHBRIDGE, a town of Worcester county, Massachusetts, U.S.A., on the Blackstone river, 13 m. S.E. of Worcester; served by the New York, New Haven and Hartford railroad. Pop. (1920) 10,174 (36% foreign-born white). It is a manufacturing town, making principally textile machinery, silk and cotton goods and embossed paper. Part of Uxbridge was established as the district of Northbridge in 1772, and in 1775 the district was made a town.

NORTHBROOK, THOMAS GEORGE BARING, 1ST EARL OF (1826–1904), English statesman, eldest son of the first baron (long known as Sir Francis Baring; see **BARING**), was born on Jan. 22, 1826, and educated at Christ Church, Oxford, where he graduated with honours in 1846. He was successively private secretary to Mr. Labouchere (Lord Taunton), Sir George Grey, and Sir Charles Wood (Viscount Halifax). He was member of parliament for Penryn and Falmouth (1857–66). He was a lord of the admiralty in 1857–8; under-secretary for war, 1861; for India, 1861–4; for the home department, 1864–6; and secretary to the admiralty, 1866. In the Gladstone ministry of 1868 Northbrook was under-secretary for war (1868–72). He was then governor-general of India, but resigned in 1876, because his policy of coming to an arrangement with Shere Ali, which might have prevented the Afghan War, was overruled by the duke of Argyll, then secretary of state. From 1880 to 1885 Northbrook, who had received an earldom, was first lord of the admiralty in Mr. Gladstone's second government. In Sept. 1884 Northbrook was sent to Egypt as special commissioner to enquire into its finances. He died on Nov. 15, 1904.

See B. Mallet, *Thomas George, Earl of Northbrook* (1908).

NORTH CAPE, a promontory on the island Magerö off the north coast of Norway in 70° 10' 20" N., 25° 45' E., 78 m. north-east of Hammerfest. Knivskjaerodden, an island a little to the west, is actually a little farther north than the North Cape, and Nordkyn, 45 m. farther east, is the northern extremity of the mainland (71° 7' N.). The desolate cape, rising abruptly over 1,000 ft. from the sea, is frequently visited during the summer period of the "midnight sun."

NORTH CAROLINA, popularly known as the "Tar Heel State," is one of the Atlantic coast States of the United States of America, situated between 33° 51' 37" and 36° 34' 25.5" N., and between 75° 27' and 84° 20' W. It is bounded north by Virginia, east and south-east by the Atlantic ocean, south and south-west by South Carolina, south also by Georgia, and west and north-west by Tennessee. North Carolina has an extreme length from east to west of 503½ m., which is greater than that of any other State east of the Mississippi river. Its total area is 52,426 sq.m. of which 3,686 sq.m. are water surface.

Physical Features.—The State lies wholly within the three leading topographical regions of the eastern portion of the United States: the Coastal Plain region, which occupies approximately the eastern half, the Piedmont Plateau region, which occupies about 20,000 sq.m. in the middle, and the Appalachian region, which occupies about 6,000 sq.m. in the west. At the eastern

extremity of the Coastal Plain region an outer coast line is formed by a chain of long narrow barrier beaches from which project capes Hatteras, Lookout and Fear, whose outlying shoals are known for their dangers to navigation. Between Hatteras and Lookout is Raleigh bay and between Lookout and Fear is Onslow bay; and between the chain of islands and the deeply indented mainland Currituck, Albemarle, Pamlico and other sounds form an extensive area, especially to the northward, of shallow, brackish and almost tideless water. Projecting into these sounds and between the estuaries of rivers flowing into them are extensive tracts of swamp land—the best known of these is Dismal Swamp, which lies mostly in Virginia and is about 30 m. long and 10 m. wide. Through most of the Coastal Plain region, which extends inland from 80 to 150 m. the country continues very level or only slightly undulating, and rises to the westward at the rate of little more than one foot to the mile. The "Fall Line," the boundary between the Coastal Plain and the Piedmont Plateau, has a very irregular course across North Carolina, but lies in a general south-west direction from the Falls of Roanoke between Halifax and Northampton counties to Anson county on the South Carolina border and marks a rapid increase in elevation of about 200 feet. The Piedmont Plateau region extends from this line to the Blue Ridge Escarpment, toward which its mean elevation increases at the rate of about 3½ ft. to the mile. The south-east face of the Blue Ridge Escarpment, which rises precipitously 1,200–1,500 ft. or more above the Piedmont Plateau, forms the south-east border of North Carolina's Appalachian mountain region, which includes the high Unaka mountain range, segments of which are known by such local names as Iron mountains, Bald mountains and Great Smoky mountains. These ranges reach their culmination in this State, and with a series of more or less interrupted cross ranges constitute the greatest masses of mountains in the east half of the United States. Four peaks along the Blue Ridge have an elevation exceeding 5,000 ft., and about 30 peaks in the Unakas and in the several cross ranges exceed 6,000 ft., the highest being Mt. Mitchell or Mitchell Dome (6,711 ft.), of the Black mountains, a short cross range extending north from the Blue Ridge through Yancey county. Other noteworthy peaks are Black Brother (6,690 ft.) and Hairy Bear (6,681 ft.), the next highest mountains. The valleys are usually narrow and deep, though few descend to less than 2,000 ft. above the sea.

From the Black mountains, the streams flow as from a ridge pole, some to the Atlantic, others to the Mississippi and finally to the Gulf of Mexico. West of Blue Ridge the Hiwassee, the Little Tennessee and the French Broad rivers flow west or north-west into Tennessee. Farther north are the headwaters of the New river, which finds its way to the Ohio. On the south-east slope of the Blue Ridge rise the Broad, the Catawba and the Yadkin, which first flow north-east, then finding a passage across one of the ridges of the Piedmont Plateau, turn to the south-south-east and across the boundary line into South Carolina, in which State their waters reach the Atlantic. In the north-west part of the Piedmont Plateau region rises the Dan, which in its north-east course crosses the boundary into Virginia, where it becomes a tributary of the Roanoke, in which its waters are returned to North Carolina near the "Fall Line." The other principal rivers—the Cape Fear, the Neuse and the Tar—rise in the north-east part of the Piedmont Plateau region, have their south-east courses wholly within the State, and, with the Roanoke, drain the Coastal Plain region. In the Mountain region and in the Piedmont Plateau region the rivers have numerous falls and rapids which afford a total water power unequalled perhaps in any other States than New York and Georgia east of the Mississippi river, the largest being on the Yadkin, Roanoke and Catawba; and in crossing some of the mountains, especially the Unakas, the streams have carved deep narrow gorges that are much admired for their scenery. In contrast with the rivers of these regions those of the Coastal Plain are sluggish, and toward their mouths expand into wide estuaries.

Climate and Soil.—North Carolina has a climate which varies from that of the south-east corner, which approaches the subtropical, to that of the Mountain region, which is like the medium

MAP SHOWING THE MAIN ROADS IN NORTH CAROLINA

continental type, except that the summers are cooler and the rainfall is greater. The mean annual temperature for the State (below an elevation of 4,000 ft.) is about 59° F. For the Coastal Plain region it is 61° F; for the Piedmont Plateau region, 60° F; for the Mountain region, 56° F; for Southport, in the south-east corner of the State, 64° F; and for Highlands, at an elevation of 3,817 ft. in the south-west corner, 50° F. Extremes have ranged from -19° F at Highlands to 107° F at Chapel Hill, Orange county, in 1900 and again in 1902. The average precipitation for the State is about 52 in. a year, nearly all of it in the form of rain. For the Coastal Plain region it is 54 in.; for the Piedmont Plateau region, 48 in.; and for the Mountain region 53 inches. On the east slope of some of the mountains the rainfall is exceedingly heavy. The winds are variable and seldom violent, except along the coast during the sub-tropical storms of late summer and early autumn.

On the Coastal Plain the soil is generally sandy, but in nearly all parts of this region more or less marl abounds; south of the Neuse river the soil is mostly a loose sand, north of it there is more loam on the uplands, and in the lowlands the soil is usually compact with clay, silt or peat; toward the western border of the region the sand becomes coarser and some gravel is mixed with it. The entire Piedmont region is underlain by crystalline rocks, such as granite and schists. The soils are, for the most part, red sandy loams and clay loams, gravelly and sandy in spots.

Population.—The estimated population in 1928 was 2,938,000 as compared with 2,559,123 in 1920, a gain of 378,877, or 14.8%. North Carolina in 1920 ranked, in population, 14th among the States of the Union. The population of the State at certain other censuses was as follows: 393,751 in 1790; 478,103 in 1800; 992,622 in 1860; 1,071,361 in 1870; 1,617,949 in 1890; 1,893,810 in 1900; and 2,206,287 in 1910. Of the total in 1920 only 7,099, or slightly over one-fourth of 1% were foreign-born, a smaller foreign admixture than that of any other State. According to race distribution 1,783,779 were whites, 763,407 negroes, 11,824 Indians and 112 Japanese and Chinese. Until nearly a century after the founding of the Carolinas there was not a town in North Carolina that had a population of 1,000, and the urban population of the State was exceptionally small at the beginning of the rapid rise of the manufacturing industries about 1880. In 1920 the urban population (in places having 2,500 inhabitants or more) was 490,370, or 19.2% of the total as compared with 14.4% in 1910. The density of population in 1920 was 52.5 persons per square mile. The chief cities in 1928 and their population were Winston-Salem, 80,000; Charlotte, 82,100; Greensboro, 51,900; Durham, 47,600; and Wilmington, 39,100. According to the U.S. Census estimate in 1926, Asheville had a population of 31,474 and Raleigh, the State capital, 30,371.

Government.—North Carolina has been governed under the charters of 1663 and 1665 (1663-1729), under commissions and instructions from the crown (1729-76), and under the State Constitutions of Dec. 1776 and of April 1868, with numerous amendments. The present Constitution, as amended, prescribes that no convention of the people of the State may be called by the legislature unless by the concurrence of two-thirds of all the members of each house followed by an affirmative vote of a majority of the electors voting on the question; and that an amendment to the Constitution may be adopted only by a three-fifths vote of each house followed by an affirmative vote of the majority of electors voting on the question. The suffrage provisions containing the famous "grandfather clause" (in Art. vi, section 4), were adopted in the form of a constitutional amend-

GRAPH SHOWING GROWTH OF POPULATION AND RELATIVE PROPORTIONS OF WHITES AND NEGROES IN NORTH CAROLINA, 1790-1920

ment, ratified in Aug. 1900, and in effect July 1, 1902. Since Dec. 1, 1908, all new applicants otherwise qualified may place their names on the voting register, provided they can read and write any section of the Constitution in the English language.

Perhaps the most notable feature about the administration is the weakness of the governor's position. He is elected by popular vote for four years, and cannot succeed himself in office. His power is limited by a council of State, a relic of colonial days. This body is not, however, a special board, as in Maine, New Hampshire and Massachusetts, but a kind of administrative

cabinet consisting of the secretary of State, the auditor, the treasurer and the superintendent of public instruction, advising the governor in the administration of his office. Judges, heads of departments, and executive boards are elected, and in most instances in which the governor appoints to office the confirmation of the senate is necessary. Furthermore, in North Carolina the governor has no veto power. In addition to the executive officials mentioned above there are a lieutenant governor, and attorney-general, a commissioner of agriculture, a commissioner of labour and printing, a commissioner of insurance and a commissioner of revenue, all elected for a term of four years.

Sessions of the general assembly are held biennially, beginning on the Wednesday after the first Monday in January, in odd-numbered years. The senate is composed of 50 members elected biennially from 33 senatorial districts, and the house of representatives of 120, elected biennially and chosen by counties according to their population, each county having at least one representative, no matter how small its population. The pay for both senators and representatives is four dollars per day for a period not exceeding 60 days, and mileage; should the session be prolonged the extra service is without compensation.

There is a supreme court consisting of a chief justice and four associates, elected by popular vote for eight years, and a superior or circuit court, composed of 20 judges elected by the people in each of 20 districts for a term of eight years. Minor civil and criminal cases are tried before a justice of the peace or municipal judge. The county officials are the sheriff, a coroner, a treasurer, a register of deeds, a surveyor and three or five commissioners, elected for two years; a clerk of the court elected for four years; a county board of education, elected or appointed for two years; and a superintendent of schools and a superintendent of public welfare, appointed for a term of two years.

Finances.—North Carolina was one of the few States in the Union in 1926, that had no State tax on property. The total of the State's general fund revenues for the fiscal year ending June 30, 1926, was \$13,878,552; the principal sources being income (\$6,111,037), insurance (\$1,236,593), inheritance (\$886,376), franchise (\$1,649,268), utilities (\$1,285,685), corporation (\$270,313), and bus (\$145,058) taxes. The average rate of county taxation in 1925 was \$1.28 per \$1,000 of valuation on assessed property values of \$2,706,032.819. The chief sources of the special fund revenues were automobile licences (\$7,213,854), a gasoline tax (\$7,166,008) and the departments and institutions funds (\$2,611,203). General fund disbursements for the fiscal year 1926 were \$13,459,815. Of this amount, the chief disbursements were for State educational institutions (\$3,882,256), administrative departments, boards and commissions (\$3,073,552), maintenance of charitable and correctional institutions (\$2,498,658), interest sinking funds and debt payments (\$1,954,412) and pensions (\$1,004,252). Of the special fund disbursements the greater were for road construction and maintenance (\$23,833,350), institution buildings (\$2,800,273) and interest (\$3,395,110). The total indebtedness of the State on June 30, 1926, was \$123,788,000 in bonds and \$20,300,000 in loans. Of the bonded debt, \$69,999,600 were for highway construction, \$22,519,000 for educational and charitable institution improvement, \$10,000,000 for public school building bonds, and the remainder for funding and miscellaneous improvements.

Education.—The public school system of North Carolina has made remarkable and well rounded progress since 1900. The public school funds increased from approximately \$3,000,000 in 1910 to \$35,000,000 in 1925. The total school expenditures increased from \$1,248,157 in 1901 to \$32,443,426 in 1926, or from a per caput of \$2.87 to \$39.63. The per caput cost for rural school education in 1926 was \$34.11 as compared with \$57.25 for city schools. In 1901 there were 8,320 teachers and 435,184 enrolled pupils as compared with 23,128 teachers and 818,793 pupils in 1926. Of the 1926 enrolment, 623,760 were in rural schools and 195,033 in city schools. The high school enrolment increased from 63,499 in 1923-24 to 81,605 in 1925-26. Of the 1925-26 total 45,440 were enrolled in rural high schools and 36,165 in city high schools; 8,237 were coloured and 73,368 were whites.

The number of consolidated schools increased from 228 in 1921-22 to 657 in 1925-26. In the latter year, transportation was furnished for 87,283 pupils. A programme of vocational education as a part of the State's policy of public education was inaugurated in 1917-18 after the passage of the Smith-Hughes vocational education act made available Federal funds. There were in 1926, 111 schools giving instruction in agriculture and 147 giving courses in home economics. The average annual salary for white teachers was \$853 and for negro teachers \$467.

Chief among the State institutions of higher learning is the University of North Carolina at Chapel Hill, chartered in 1789 and opened in 1795, one of the oldest State universities in the country and one of the oldest universities in the South. In 1925-26 it had a total enrolment of 7,061 students, of which 2,505 were resident students during the main term. Other schools maintained by the State are the North Carolina College of Agriculture and Engineering at Raleigh, the North Carolina college for women at Greensboro, the East Carolina Teachers college at Greenville, the Cullowhee State normal school at Cullowhee and the Appalachian State normal school at Boone. State-supported negro institutions include the Negro Agricultural and Technical college of North Carolina at Greensboro, the Winston-Salem Teachers college at Winston-Salem, North Carolina college for negroes at Durham, and normal schools at Fayetteville and Elizabeth City. A school for the Cherokee Indians of Robeson county is located at Pembroke. Among the non-State supported institutions of higher education Duke university, formerly Trinity college, at Durham, is the greatest. It received from the late James B. Duke the sum of \$6,000,000 for building and an endowment fund estimated to amount to anywhere from \$80,000,000 to \$100,000,000, one of the largest foundations for education and hospitalization in the world. Well known sectarian schools are Wake Forest college at Wake Forest; Davidson college at Davidson; Greensboro college for women at Greensboro; Guilford college for women near Greensboro; Lenoir-Rhyne college at Hickory; Catawba college at Salisbury; Meredith college at Raleigh; Belmont Abbey college at Belmont; Elon college at Elon; and Atlantic Christian college at Wilson. Institutions for negroes include Shaw university at Raleigh, Johnson C. Smith university at Charlotte, Livingston university at Salisbury and St. Augustine's school at Raleigh.

Charities and Corrections.—The chief State-supported institutions in 1927 consisted of hospitals for the white insane at Raleigh and Morganton and a hospital for negro insane at Goldsboro, the Caswell Training school for mental defectives at Kingston, the North Carolina Orthopaedic hospital for crippled children at Gastonia; the Stonewall Jackson Training school for delinquent white boys at Concord, the Eastern Carolina Industrial Training school for delinquent white boys at Rocky Mount, the Morrison Industrial school for delinquent negro boys at Hoffman, the Samarcand Manor for delinquent white girls at Samarcand and the State prison at Raleigh.

Agriculture.—North Carolina, in 1926, ranked sixth among the States in the value of its agricultural products, the total crop values being estimated at \$327,700,000. In that year, the State ranked first in the production of tobacco and of peanuts and third to Georgia and Texas in the production of sweet potatoes. The principal crops in 1926, their acreage, yields and values are as follows: tobacco 574,000 ac., 393,190,000 lb., \$103,802,000; cotton, 2,023,000 ac., 1,250,000 bales, \$71,875,000; Indian corn, 2,376,000 ac., 52,272,000 bu., \$45,999,000; hay 816,000 ac., 738,000 tons, \$14,552,000; potatoes 74,000 ac., 7,400,000 bu., \$11,840,000; wheat 447,000 ac., 6,303,000 bu., \$9,013,000; peanuts 194,000 ac., 190,120,000 lb., \$7,985,000; sweet potatoes 84,000 ac., 7,560,000 bu., \$7,560,000; oats 310,000 ac., 6,820,000 bu., \$4,706,000; rye 104,000 ac., 1,352,000 bu., \$1,690,000.

In the production of vegetables and fruits the State ranks high. In 1926 the orchards yielded 5,986,000 bu. of apples, 2,100,000 bu. of peaches and 270,000 bu. of pears. The vineyards of the State produced 6,840 tons of grapes. The 5,040 ac. devoted to strawberries produced 10,821,000 quarts valued at \$1,731,360. Of the total strawberry crop 1,252 carloads were shipped out of

the State.

The live stock on the farms of North Carolina in 1927 consisted of 513,000 cattle, of which 303,000 were kept for dairy purposes; 849,000 swine; 279,000 mules; 114,000 horses and 77,000 sheep; their total value was estimated at \$69,120,000. The value of the dairy products in 1924 was \$14,095,407; and of the eggs and chickens produced, \$18,120,881.

The tendency noted in 1910 and 1920 toward smaller holdings was also evident in 1925; in the last mentioned year, the average size farm was 65.6 acres. In 1925 the farm acreage was 18,593,670 as compared with 20,021,736 in 1920. During the same period the number of farms increased from 269,763 to 283,482. Of the total number of farmers, 202,516 were whites and 80,966 coloured. The greater part of the coloured farmers (58,865) were tenants. The total number of tenants was 128,254, or 45.2% of the farmers as compared with 43.5% in 1920. The total farm population in 1925 was 1,446,881 as compared with 1,501,227 in 1920.

Forests and Fisheries.—North Carolina had in 1925, 1,047 active saw mills which produced 1,040,735,000 bd.ft. of sawed lumber as compared with 1,286,638,000 bd.ft. in 1899 and 2,177,715,000 bd.ft. in 1909. Of the 1925 production, 843,755,000 bd.ft. were classified as softwood, chiefly, yellow pine (750,475,000 bd.ft.), spruce (38,463,000 bd.ft.), cypress (24,446,000 bd.ft.) and hemlock (21,650,000 bd.ft.); and 196,980,000 bd.ft. as hardwood, principally, oak (82,334,000 bd.ft.) chestnut (41,164,000 bd.ft.), red gum (21,681,000 bd.ft.) and yellow poplar (21,140,000 bd.ft.). Other species of some importance were hickory, cedar and ash. The early and continued production of rosin, turpentine and tar from the long-leaf pine forests of the coastal plain has caused North Carolina to be popularly called the "Tar Heel State." The value of the lumber and timber products in 1925 was \$38,080,932.

In the sounds along the coast, in the lower courses of the rivers that flow into them, and along the outer shores, fishing is an important industry. In 1923, there were 141 vessels and 9,308

DIAGRAM SHOWING TOBACCO CROP OF NORTH CAROLINA 1909-1927

persons engaged in the industry; the product was 95,192,343 lb. valued at \$2,414,499.

Minerals.—During the first half of the 19th century North Carolina was a mining State of the first importance, but in 1925 it ranked 38th among the States of the Union. The total value of the mineral products of the State, in the latter year, was \$9,504,063, or 19% of the total for the United States. The principal minerals produced, ranked according to value, were clay products (\$3,868,962), stone (\$3,478,855), sand and gravel (\$886,351), crude feldspar (\$496,563), coal (\$283,000), mica (\$180,194) iron ore (\$49,511), gold (\$18,540) and silica (\$10,692). In 1924, North Carolina's output of crude feldspar constituted 47% of the total quantity and 42% of the total value of that mineral produced in the United States. Feldspar was produced chiefly

in Mitchell, Yancy and Avery counties. North Carolina also ranked first in the production of mica, which is found in the north-eastern portion of the mountain region. Granite, suitable for building stones and paving blocks, is found in most parts of the State west of the "Fall Line." Talc also is widely distributed in the State.

Manufactures.—North Carolina in 1925 ranked second to Texas among the Southern States and 15th among the States of

RELATIVE IMPORTANCE OF THE PRINCIPAL MANUFACTURES OF NORTH CAROLINA, 1925

the Union in the value of her manufactured products. This industrial pre-eminence has been gained since 1880. Industrial leadership in the manufacture of cotton goods and tobacco products has been achieved principally by an abundant supply of raw materials, favourable climatic conditions, a reliable supply of native labour and cheap hydro-electric power. The State department of conservation and development estimated in 1925 that over 50% of North Carolina's knitting mills, 50% of her furniture factories, 90% of her tobacco manufacturing industries and over 90% of her textile spindles were electrically driven. In 1925, 597,000 h.p. was developed by water-power in North Carolina. In the same year it was estimated by the U.S. Geological Survey that the State had undeveloped water-power resources equal to 540,000 horse-power. The total value of the manufactured products of the State in 1880 was \$20,095,037; in 1914 it was \$289,412,000.

A comparison of the value of the manufactured products in 1914 with that of 1925 shows an increase of \$761,022,000, or approximately 263%. In the latter year, the State's 2,614 industrial establishments, with a product exceeding \$5,000, employed 182,234 wage-earners and had an output valued at \$1,050,434,117. The following table shows the principal industries in 1925, the number of establishments, the average number of wage-earners and the value of the product:

Industry	Number of establishments	Wage-earners	Value
			\$
Cotton goods	364	84,130	316,068,431
Cigars and cigarettes	12	13,133	312,736,113
Furniture	127	13,567	51,208,238
Knit goods	111	13,727	44,300,819
Lumber and other timber products	515	17,787	38,080,932
Cheewing and smoking tobacco and snuff	9	2,582	30,339,494
Fertilizers	65	1,796	20,068,540
Flour and grain-mill products	115	484	18,201,542
Cotton seed oil, cake and meal	51	1,426	17,484,244
Planing mills	154	2,982	15,081,683

Gaston county, with the industry centred chiefly at Gastonia and Belmont, was the leading textile producing county in the United States in 1925. Other important textile producing counties of North Carolina were Alamance, Cleveland and Mecklenburg. Nearly 50% of the tobacco factories were situated in the city of Winston-Salem and over 80% of the total value of the yearly output was reported from that city. Others in which the industry flourished were Durham, Greensboro, Reidsville and Statesville. The chief centre of the furniture industry was High Point in Guilford county. Other centres of importance were Winston-Salem, Thomasville, Hickory, Lexington, Mount Airy, Salisbury and Lenoir.

Transportation.—Railway building was begun in the State in 1836 with the Raleigh and Gaston line, opened from Raleigh to Gaston in 1844 and extended to Weldon in 1852. The steam railway mileage in 1925 was 5,347 as compared with 5,565 in 1915. The eight electric railway companies in the State in 1925

had a total of 355 m. of track, of which about 200 m. were main line. Since 1920 great progress has been made in developing a great system of highways. The State highway system on Jan. 1, 1927, had a mileage of 6,218; of this total 5,464 m. were surfaced. During 1926, 696 m. of new surfacing were placed. The total highway expenditures made by or under the direction of the State department amount to over \$30,000,000 annually. There were, in Aug. 1927, according to the State corporation commission, 97 passenger bus lines operating on 4,500 m. of road and 17 motor freight and express lines over 1,756 m. of road. The total motor vehicle registration for 1926 was estimated at 389,586. Wilmington, the deep-water port, had in 1926 a water-borne trade of 196,285 tons of imports and 23,699 tons of exports.

History.—The history of North Carolina may be divided into four main periods: the period of discovery and early colonization (1520-1663); the period of proprietary rule (1663-1729); the period of royal rule (1729-76); and the period of Statehood (from 1776).

It is possible that some of the early French and Spanish explorers visited the coast of North Carolina, but no serious attempt was made by Europeans to establish a settlement until near the close of the 16th century. After receiving from Queen Elizabeth a patent for colonization in the New World, Sir Walter Raleigh, in April 1584, sent Philip Amadas, or Amidas (1550-1618), and Arthur Barlowe (c. 1550-c. 1620) to discover in the region bordering on Florida a suitable site for a colony. They returned in September with a glowing account of what is now the coast of North Carolina, and on April 9, 1585, a colony of about 108 men under Ralph Lane (c. 1530-1603) sailed from Plymouth in a fleet of seven small vessels commanded by Sir Richard Grenville. The colony was established at the north end of Roanoke island on Aug. 17 and about a week later Grenville returned to England. Threatened with famine and with destruction from hostile Indians, the entire colony left for England June 19, 1586, on Sir Francis Drake's fleet. Only a few days after their departure Sir Richard Grenville arrived with supplies and more colonists, 15 of whom remained when he sailed away. Although greatly disappointed at the return of the first colony, Raleigh despatched another company, consisting of 121 persons under John White, with instructions to remove the plantation to the shore of Chesapeake bay. They arrived at Roanoke island July 22, 1587, and were forced to remain there by the refusal of the sailors to carry them farther. Of the 15 persons left by Grenville not one was found alive. White's granddaughter, Virginia Dare (b. Aug. 18, 1587), was the first English child born in America. White soon returned to England for supplies, and having been detained there until 1591 he found upon his return no trace of the colony except the word "Croatan" carved on a tree; hence the colony was thought to have gone away with friendly Indians.

In 1663 Charles II. granted the territory between the 31st and 36th parallel and extending from sea to sea, to the earl of Clarendon (1609-74), the duke of Albemarle (1608-70), and six other favourites. By a second charter issued in 1665 the limits were extended to 25° and 36° 31'. The first permanent English colony in North Carolina was established at Albemarle on the Chowan river about 1666 by people from Virginia. Other settlers, chiefly Scotch, Scotch-Irish and Germans, followed down the valleys from Pennsylvania. The colony grew rapidly, and at the close of the colonial period (1776) the population numbered approximately 300,000, including about 40,000 negroes. Economic advantages seem to have been the chief motives of colonization. The proprietary period (1663-1729) was a turbulent one. Six out of 16 governors or deputy governors were driven from office between 1674 and 1712, and there were two uprisings which have been deemed worthy of the term rebellion. A war with the Tuscarora Indians, in 1711-13, resulted in the defeat of the Indians and the removal of the greater part of the tribe to New York, where they became the sixth nation of the Iroquois confederacy.

In 1729 an act was passed by parliament establishing an agreement with seven of the proprietors for the surrender of their claims to both provinces. They were allowed £17,500 for their

rights and £5,000 for arrears of quit rents. Lord Carteret, the eighth proprietor, refused to sell, but in 1744 he gave up his claim in return for a strip of land in North Carolina lying between lat. 35° 34' and the Virginia line (36° 30'). The political history during the royal period is, like that of other colonies, the story of a constant struggle between representatives of the people and the representatives of the Crown. There were disputes

BY COURTESY OF THE NEW BERN CHAMBER OF COMMERCE

CHRIST CHURCH, OF THE EPISCOPAL DENOMINATION, NEW BERN, N.C.

over questions of Government, of commerce, of finance and of religion. In the "back country" extortionate fees, excessive taxes, and the oppressive manner of collecting them brought about a popular uprising, known as the Regulation. Violence followed the refusal to pay taxes, and in Sept. 1768 Governor Tryon was forced to lead a military expedition against the Regulators. They, however, were not prepared to withstand the governor's forces and submitted without bloodshed. New outbreaks in the fall of 1770 provoked the second military expedition of the governor, and on May 16, 1771, with a force of about 1,000 men and officers, he met about twice that number of Regulators on the banks of the Alamance, where, after two hours of fighting, with losses on each side nearly equal, the ammunition of the Regulators was exhausted and they were routed. About 15 were taken prisoners, and of these seven were executed.

The first Provincial Congress met at Newbern Aug. 25, 1774 and elected delegates to the Continental Congress. A second Provincial Congress met in April 1775, and in the next month Gov. Martin sought safety in flight. A committee representing the militia companies of Mecklenburg county, on May 31, 1775, passed a series of resolutions which declared that the royal commissions in the several colonies were null and void, that the Constitution of each colony was wholly suspended, and that the legislative and executive powers of each colony were vested in its Provincial Congress subject to the direction of the Continental Congress; and the resolutions requested the inhabitants of the county to form a military and civil organization independent of the Crown of Great Britain which should operate until the Provincial Congress should otherwise provide or the British Parliament should "resign its unjust and arbitrary pretensions with respect to America." The Mecklenburg Declaration of Independence, which it is alleged was passed on May 20 by the same committee, abounds in phrases which closely resemble phrases in the great Declaration of July 4, 1776.

The first sanction of independence by any body representing the whole province was given by the fourth Provincial Congress on April 12, 1776, and the same body immediately proceeded to the

consideration of a new and permanent form of government. Their labours ended, however, in another provincial Government by a council of safety, and the drafting of North Carolina's first State Constitution was left to a Constitutional convention which assembled on Nov. 12, at Halifax.

North Carolinians fought under Washington at Brandywine and Monmouth and played a still more important part in the Southern campaigns of 1778-81. The State was twice invaded, in 1776 and in 1780-81, and two battles were fought upon her soil, Moore's Creek Feb. 27, 1776 and Guilford Court House March 15, 1781.

North Carolina sent delegates to the Philadelphia Constitutional convention of 1787, but the State convention, at Hillsboro, called to ratify the Constitution for North Carolina, did not meet until July 21, 1788, when ten States had already ratified. The document was most strongly opposed because it contained no bill of rights and on the ground that it would provide for such a strong central Government that the State Governments would ultimately be sacrificed. At the conclusion of the debate the convention by a vote of 184 to 84 declared itself unwilling to ratify the Constitution until a bill of rights had been added and it had been amended in several other particulars so as to guarantee certain powers to the States. But a second convention met at Fayetteville in Nov. 1789 and the Constitution was speedily ratified (on the 13th) by a vote of 195 to 77.

The period from 1790 to 1835 was marked by a prolonged contest between the eastern and the western counties. In 1790 the West began to urge a new division of the State into representative districts according to population and taxation. This was stubbornly resisted, and the West assumed a threatening attitude as the East opposed its projects for internal improvements for which the West had the greater need. In 1823 the West called an extra-legal convention to meet at Raleigh, and delegates from 24 of the 28 western counties responded, but a lack of agreement over the counting of slaves as well as whites as a basis of representation caused little to be accomplished. Finally in Jan. 1835 the legislature passed a bill for submitting the question of calling a Constitutional convention legally to all the voters of the State. When the popular vote was taken, in the following April, every eastern county gave a majority against the convention, but the West voted strongly for it and carried the election with a total majority in the State of 5,856 votes. In the convention, the East made some concessions: such as the popular election of the governor, the disfranchisement of free negroes, the choosing of senators from districts according to public taxes and the apportioning of commoners to districts according to population based on the Federal ratio. The electorate gave its approval to the revision by a vote of 26,771 to 21,606, and with this the agitation over representation ceased.

The fundamental points of difference between North Carolina and South Carolina were exemplified in the slavery conflict. South Carolina led the extreme radical element in the South and was the first State to secede. North Carolina held back, worked for a compromise, sent delegates to the Washington Peace convention in Feb. 1861, and did not secede until May 20, 1861, after President Lincoln's call for troops to preserve the Union. Liberal support was given to the Confederacy, both in men and supplies, but Gov. Vance, one of the ablest of the Southern war governors, engaged in acrimonious controversies with President Jefferson Davis, contending that the general Government of the Confederacy was encroaching upon the prerogatives of the separate States. Owing to its distance from the border, the State escaped serious invasion until near the close of the war. Wilmington was captured by the Federals in Feb. 1865; Gen. Sherman's army crossed the southern boundary in March; a battle was fought at Bentonville, March 19-21; Raleigh was entered on April 13; and the Confederates under Gen. Joseph E. Johnston surrendered near Durham station, in Durham county, on the 26th.

Reconstruction was a costly experience here as in other Southern States. Jonathan Worth (1802-69), elected governor under the presidential plan in 1865, was an honest and capable official, but the Government established in accordance with the views of Congress in 1868 was corrupt, inefficient and tyrannical. Carpet-

bagger, negroes and unscrupulous native whites, known as scalawags, were in control of affairs, while the people of wealth, refinement and education were disfranchised. Gov. William Woods Holden (1818-92; governor 1868-70) was so weak and tyrannical that he was impeached by the legislature in Dec. 1870. Under his successor, Tod R. Caldwell (1818-74), there was some improvement in the condition of affairs, and in 1875 a Constitutional Convention, in session at Raleigh, with the Democrats slightly in the majority, amended the Constitution, their work being ratified by the people at the State election in 1875. The native white element completely regained possession of the Government in the following year, when the Democrats came into office under Gov. Zebulon B. Vance. Since that time the most interesting feature in the political history has been the rise and fall of the People's Party. The hard times which followed the financial panic of 1893 made it possible for them, in alliance with the Republicans, to carry the State in the election of 1894. The race question was the chief issue in the election of 1898, the Democrats were successful, and what amounted to a negro-disfranchising amendment to the Constitution was adopted in Aug. 1900. In the presidential election of 1928, the Republican candidate carried North Carolina by 62,000 votes.

Knight, *Our State Government, an Elementary Text in the Government of North Carolina* (2 vol. in N.C. Historical Commission Publications) and the *Biennial Reports of the department of public instruction*.

The best bibliographies are S. B. Weeks, *A Select Bibliography of North Carolina* (1913, a bulletin of the N.C. Library commission) and the first section of W. K. Boyd and J. G. de R. Hamilton, *A Syllabus of North Carolina History* (1913). General surveys of North Carolina history are: *History of North Carolina* by R. D. W. Connor, W. K. Boyd, J. G. de R. Hamilton and three volumes of biography by a special staff (6 vol. 1919); John W. Moore, *History of North Carolina* (2 vol. 1880); and S. A. Court Ashe, *History of North Carolina* (2 vol. 1908). For the colonial and revolutionary period there are some excellent studies. Charles S. Cooke, "The Governor, Council and Assembly in Royal North Carolina" in the *James Sprunt Historical Monographs* (vol. xii, No. 1, 1912); C. L. Raper, *North Carolina: A Study in English Colonial Government* (1904); J. S. Bassett, *Constitutional Beginnings of North Carolina* (1894); *The Regulators of North Carolina* (1894); and *Slavery in the State of North Carolina* (1899). S. W. Weeks deals with the religious history in his *Religious Development in the Province of North Carolina* (1892), *Church and State in North Carolina* (1893) and *Southern Quakers and Slavery* (1896). E. W. Sikes, *The Transition of North Carolina from Colony to Commonwealth* (1898), based on the public records, is accurate, though dull. Among the controversial works on the Mecklenburg Declaration of Independence are W. H. Hoyt's *The Mecklenburg Declaration of Independence* (1907), which adopts the view held by many competent historians that the alleged declaration is spurious; and G. W. Graham, *The Mecklenburg Declaration of Independence* and J. W. Moore, *Defence of the Mecklenburg Declaration of Independence* (1909), are attempts to prove the same declaration genuine. For the Reconstruction period see J. G. de R. Hamilton, *Reconstruction in North Carolina* (1913); Hilary A. Herbert et al., *Why the Solid South? or Reconstruction and its Results* (1890); and *House Report 22, 42nd Congress, 2nd session* (13 vol. 1872; vol. ii. deals with North Carolina). For works covering various phases of the State's history, Government and social life see the *James Sprunt Historical Publications of the University of North Carolina* (1900 seq.); the *Publications of the North Carolina Historical Commission*; and the *Historical Publications of North Carolina College for women* (1914-seq.). The chief published sources are *The Colonial and State Records of North Carolina* (30 vol. 1886-1914); see also "Report of the Public Archives of North Carolina" in the *Annual Report of the American Historical Association* vol. ii. (1901).

NORTH CHICAGO, a manufacturing city of Lake county, Illinois, U.S.A., on Lake Michigan, 35 m. N. by W. of Chicago, between Waukegan (on the north) and the Great Lakes Naval

Training station. It is served by the Chicago and North Western, the Chicago, North Shore and Milwaukee, and the Elgin, Joliet and Eastern railways. Pop. 5,839 in 1920 (33% foreign-born white).

NORTHCLIFFE, ALFRED CHARLES WILLIAM HARMSWORTH (1865-1922), VISCOUNT, British newspaper proprietor, was born on July 15, 1865 at Chapelizod, Dublin, the eldest of a family of fourteen. His father, Alfred Harmsworth (1837-1889), descended from an old Hampshire family, was a barrister-at-law of the Middle Temple. His mother, Geraldine Mary, who died Aug. 29, 1925, a woman of remarkable intellect and strong character, was a daughter of William Maffett.

Of the seven sons, the two eldest, Alfred and Harold, became members of the House of Lords as Lord Northcliffe and Lord Rothermere respectively; the third, Cecil Bisshopp (b. 1869), became in 1915 under-secretary for home affairs and in 1919 under-secretary for foreign affairs, having entered the House of Commons as Liberal M.P. for Droitwich (1906-10) and subsequently sitting for S. Beds; while the fourth, Robert Leicester (b. 1870), who was created a baronet in 1918, entered the House of Commons in 1900 as Liberal M.P. for Caithness, a seat which he retained till 1922. The other three sons were Hildebrand Aubrey (b. 1872), from 1901 to 1904 editor of *The New Liberal Review*; St. John (b. 1876), the creator of the Perrier mineral water business; and Vyvyan George (b. 1881).

Early Journalism.—The Harmsworths moved to London in the year 1867, and at Henley House school, West Hampstead, the boy Harmsworth started in 1878 the first of his journalistic adventures, a school magazine. This was originally issued in ms. but was afterwards printed and sometimes set up by himself in his spare time. At 15 he did some work for Mr. Jealous, then editor of *The Hampstead and Highgate Express*. As secretary and companion to one of Lord Lilford's sons, he travelled extensively in Europe. On his return to London he became assistant editor of *Youth* and contributed articles to *The Morning Post*, and to the *St. James's Gazette*.

But his health temporarily broke down in 1884. Ordered to live out of London, he went to Coventry in 1885 and worked for the firm of Iliffe and Sons, owners of many publications. With them he remained till 1886, and he then went back to London and joined a general publishing business. Among other ventures he started on June 16, 1888 *Answers to Correspondents*, a weekly periodical intended to be a more popular form of *Notes and Queries*. As *Answers* it laid the foundation of what eventually became the largest periodical publishing business in the world, the Amalgamated Press. Alfred Harmsworth had already been joined by his second brother, Harold (see **ROTHERMERE, VISCOUNT**). The two brothers revolutionized the current methods of periodical journalism. The profits of the accumulated publications soon soared to £50,000 a year. In the next few years Alfred Harmsworth travelled much in Europe, India, Africa, Canada and the United States. On April 11, 1888 he had married Mary Elizabeth, daughter of Robert Milner, a West Indian merchant.

On Aug. 31, 1894 he and his brother Harold acquired the London *Evening News*, in which the Conservative party had sunk some £300,000. It was then losing money heavily, but it was at once reorganized with such effect that the first working week yielded a profit of £7, and the first year one of £14,000. In the same year he fitted out an Arctic expedition under Mr. F. G. Jackson, which explored Franz Josef Land. In the general election of 1895 he stood unsuccessfully as a Conservative candidate for Parliament at Portsmouth.

The Daily Mail.—On May 4, 1896 a new halfpenny morning paper, *The Daily Mail*, was launched, "the busy man's newspaper," as he called it. It embodied many innovations, a very full service of cables, the employment of numerous famous writers, condensation of unimportant topics, and costly and daring enterprises of various kinds. A comparison of past files of the London Press shows how it revolutionized daily journalism. One of the three leading articles in the first number dealt with the then almost unknown motor-car, in the future of which Alfred Harmsworth had a firm belief, being himself already a qualified

driver. *The Daily Mail* attained a sale of 600,000 copies a day in the Boer War, and acquired sound influence on national policy at home and abroad.

In 1903 he founded *The Daily Mirror*; it was at first a complete failure, losing £1,500 a week but after being transformed from a penny paper for women into a halfpenny illustrated morning journal, became as signal a success. In 1905 a Continental edition of *The Daily Mail* was established, with headquarters in France. In 1904 Alfred Harmsworth was created a baronet, and in 1905 he was raised to the peerage as Baron Northcliffe. In 1906 he and his brothers acquired for their companies about 3,000 sq.m. of forest land in Newfoundland, with lakes, rivers and water transport, for the manufacture of paper and wood pulp, the result being the formation of the Anglo-Newfoundland Development Co., a gigantic enterprise with its works at Grand Falls, and two lines of railway, a port and Atlantic and other steamers.

In 1908 Lord Northcliffe obtained control of *The Times*, to own which had always been one of the aims of his life. New machinery was installed, and the size of the paper greatly increased; in March, 1914, he reduced the price to one penny, with the result of a large increase in circulation, though the enormous rise of 600% in the cost of paper during the World War forced a subsequent increase in price. Meanwhile Lord Northcliffe had acquired *The Weekly Dispatch*; disposed of the Sunday *Observer*, which he for some time owned; and sold *The Daily Mirror* to his brother, Lord Rothermere. Among the reforms which Lord Northcliffe introduced into newspaper management were the five-day week for editors, sub-editors and reporters, a more generous payment of journalists and a system of profit-sharing by the chief members of his staffs.

From 1900 onwards, through his newspapers, he had exercised an ever-increasing influence on politics. He had at one time been anxious, like Edward VII. and Cecil Rhodes, to obtain a friendly understanding between England and Germany, but the Boer War caused him to abandon that idea as impracticable. His newspapers consistently pleaded the cause of a strong navy, and as consistently warned the nation for 20 years of the peril from Germany. From 1902 he sought to effect an entente with France, and also to promote agreements with Russia and the United States, whose sentiments and prejudices he had learnt in many visits. Through *The Daily Mail* he gave large prizes for airmanship, in which, from 1906 onwards, he took the warmest interest. His maiden speech in the House of Lords was devoted to the pressing claims of aircraft. He was a strong believer in the future of flying and a daily advocate of the value of aircraft in war. He was also interested from the first in submarines, in one of which craft he made an early and hazardous descent.

The World War.—In the World War he aimed at the vigorous conduct of the struggle, and was from the first of opinion that the War would be long and desperately contested. The chief newspaper campaigns which he carried out, always with the aims of victory and close union between the Allies, were: (1) for the organization of the munition supply and provision of high-explosive shells in April and May 1915, when he did not hesitate to lay the responsibility for the shortage of ammunition on Lord Kitchener in leading articles written by himself in *The Daily Mail* of May 19 and 21, the second of which was publicly burned on the London and other stock exchanges; (2) this campaign was one of the causes of the formation of the Coalition Ministry by Mr. Asquith; (3) throughout 1915 and early 1916, in the teeth of storms of abuse, he urged the necessity of introducing compulsory service; (4) he protested continuously against the excessive optimism of the Asquith Government and against official secretiveness; (5) he called for the strict enforcement of the blockade; (6) so far as the censorship would allow, he resisted the Dardanelles and Salonika campaigns, which absorbed so large a part of the national forces; (7) he continued his pre-War demand for the construction of aircraft—and "the right kind of aircraft"—on the largest possible scale; (8) he urged the necessity of creating a strong naval war staff and taking offensive measures against the enemy submarines; (9) he insisted on the need of compulsory food rationing. While always active with his pen and through

his Press, he went repeatedly to the various battle-fronts, British, French, Belgian, Italian and American, and kept in close touch with the various staffs. In Dec. 1916 he gave his support to Mr. Lloyd George in the political crisis which led to the fall of Mr. Asquith's Government, and dealt the final thrust which brought that Government down, though after the Armistice, by reason of his objection to the long-drawn-out after-war negotiations with the Germans, he became Mr. Lloyd George's most persistent critic. He was offered office but declined.

Work in New York.—Before the United States entered the War he was offered and declined the post of British ambassador at Washington. But he went to New York (June 2, 1917) as chairman of the much-needed British War Mission returning to London on Nov. 12, 1917, when he was created a viscount, as Viscount Northcliffe of St. Peter-in-Thanel, for his services. On Feb. 13, 1918, he became director of propaganda in enemy countries. To pave the way for operations among the nationalities subject to the Habsburgs, he secured an agreement between the Yugoslavs and the Italian Government, which played a big part in the defeat of the Austrian Army and was subsequently embodied, in substance, in the peace terms. An account of his work was given in Sir Campbell Stuart's *Secrets of Crewe House* (1920); Crewe House being the London headquarters of the organization.

Last Days.—During the Peace Conference Lord Northcliffe's Press and the *Continental Daily Mail* especially exerted a powerful influence on the British Government, extracting from Lloyd George a promise to fulfil election pledges and striving to maintain the closest and most cordial relations with France. In July 1921 he went for a prolonged tour of the world, as he was medically advised to take a rest cure. A complete breakdown followed, and after a long illness he died on Aug. 14, 1922 of ulcerative endocarditis.

NORTHCOTE, JAMES (1746–1831), English painter, was born at Plymouth on Oct. 22, 1746. He was apprenticed to his father, a poor watchmaker, but in 1769 left his father and set up as a portrait-painter. In 1773 he went to London and was admitted as a pupil into the studio and house of Reynolds. At the same time he attended the Academy schools. In 1775 he left Reynolds, and, about two years later went to study in Italy. On his return to England he settled in London, where Opie and Fuseli were his rivals. He was elected associate of the Academy in 1786, and full academican in the following spring. Northcote's works are said to number two thousand, and he made a fortune of £40,000. Apart from his painting he wrote lives of Reynolds (1813), and of Titian (1830), and two series of *Fables*. He died on July 13, 1831.

NORTHCOTE, STAFFORD HENRY, 1ST BARON (1846–1911), was educated at Eton and at Merton college, Oxford. He became a clerk in the foreign office in 1868, acted as private secretary to Lord Salisbury, and was attached to the embassy at Constantinople from 1876 to 1877. From 1877 to 1880 he was secretary to the chancellor of the exchequer, was financial secretary to the war office from 1885 to 1886, surveyor-general of ordnance, 1886 to 1887, and charity commissioner, 1891 to 1892. In 1887 he was created a baronet. In 1880 he was elected M.P. for Exeter as a Conservative, and retained the seat until 1899, when he was appointed governor of Bombay (1899–1903), being created a peer in 1900. Northcote was appointed governor-general of the Commonwealth of Australia in 1903, and held this post till 1908. He died on Sept. 29, 1911.

NORTH DAKOTA, the "Flickertail State," is one of the North-central group of the United States, and lies between 45° 55' and 49° N. and 96° 25' and 104° 3' West. It is bounded north by the provinces of Saskatchewan and Manitoba in Canada, east by Minnesota, from which it is separated by the Red river, south by South Dakota and west by Montana. Its extreme length east and west is 360 m., its extreme width north and south is 210 miles. Its total area is 70,837 sq.m. of which 654 sq.m. are water surface. The original territory of Dakota was so called because of its being the home of the Dakota Indians, the word "Dakota" meaning

"allied" in the language of these tribes.

Physical Features.—In crossing North Dakota from east to west three distinct plains are encountered, rising one above the other. The most easterly of these from 790 to 965 ft. in elevation, is the remarkably level valley floor of the Red river extending from the left river bank 30 to 40 m. westward into the State. This valley was once the bed of a great glacial lake (Lake Agassiz),

formed by the retreating ice sheet damming the natural northern outlet. Its floor is covered by the rich, silty lake deposits, coloured black by decayed vegetation, which make it one of the most fertile tracts on the continent. Being free from rocks, trees and hills, its wide areas were quickly brought under cultivation by the pioneer, and the valley has continued one of the famous grain-producing regions of the United States.

West of this valley, and between it and the Missouri plateau, is an intermediate plain, ranging from 1,300 to 1,650 ft. in elevation, so covered everywhere with glacial drift that it is usually known as the drift plain. Its east and west width varies from about 70 m. at the south to over 200 m. along the Canadian boundary. The surface of this plain, varying from gently undulating to rolling and hilly, was largely determined by the irregular drift deposit which covers the pre-glacial surface to a depth of 150 to 300 feet. Across the plain from north-west to south-east, a number of irregular ridges or glacial moraines mark successive haltings of the retreating ice sheet. Especially in these moraines, but generally characteristic also of the entire drift area, are the little lakes, varying in diameter from a few yards to a few miles, which occupy the numerous sags and swales. Many of these have no outlet and are strong with salt and alkali. The largest of this character is Devils lake, an irregular body of water about 40 m. in length and 400 sq.m. in area, which forms a natural reservoir for a large area in the north-eastern part of the drift plain which has no other drainage. The drift plain has few rivers, and those of importance, the Mouse, James and Sheyenne have narrow valleys with sharp, deep banks. The lack of well-developed river valleys and the undisturbed surface of the glacial drift indicate a youthful land, little affected as yet by erosion. The soil of its rolling slopes is excellent for most grain crops and this region holds the major portion of the farming population in the State.

The drift plain is bounded on the west by an escarpment beyond which lies the third and highest plain, the so-called Missouri plateau. The escarpment itself extends from north-west to south-east in a great bow approximately parallel to, but 50 to 60 m. east of the Missouri river. In the north it forms the water-parting between the streams that run into the Missouri river and thus to the Gulf of Mexico and those that flow into the Mouse or Souris river and are carried to Hudson bay. For a long period this escarpment marked the division between farming lands of the east and grazing lands to the west, but dry-land farming methods have created many farming communities west of the ridge wherever the surface of the land is favourable.

As the Missouri river marks approximately the lower edge of the ice sheet and west of this stream the region is almost free from glacial deposits, a marked contrast in the nature of the country is presented. The sands and clays west of the river are fine and soft, and as there is scant vegetation to protect the hill-sides they are easily eroded by the rains and winds. Much of the region is so cut by deep coulees and sharp embankments and travelling is so difficult that the early French explorers called the region *les terres mauvaises*, and in its English equivalent, "the bad lands," this appellation still remains. The picturesque effect of the sculpturing by wind and rain is enhanced by the brilliant colours along the faces of the hills and ravines—grey, yellow, black and every shade of red and brown. Here and there black seams of lignite coal protrude. Here too are found petrified forests, and other fossilized evidences of a vegetation and animal growth which long ago disappeared. While the lands are not inviting to the farmer, the ranchman finds deep grassy valleys which provide good winter shelter for his cattle. The "bad lands" are best developed along the principal tributary of the Missouri in this region, the Little Missouri river, together with its numerous branches, but they are by no means confined to that drainage basin. Other important tributaries of the Missouri from the west are the Knife, Heart and Cannonball rivers. A feature of this south-western portion of the State is the large number of buttes rising 400 to 700 ft. above the general level so as to form prominent landmarks, those best known being Black Butte, Sentinel Butte, Camel's Hump and Killdeer mountain.

In North Dakota, except where they have been planted by the farmers, trees are found only in the Turtle mountains, a group of high hills near the Canadian border, in the region about Devil's lake, in the vicinity of streams, and in a few other places sheltered from the wind and sun. The woodland area of the State is estimated at but 600 sq.m., or less than 1% of its entire surface. The prairies of the more humid regions are covered with valuable grasses, and with masses of showy native flowers which bloom from spring to autumn. Cottonwoods flourish along the Little Missouri, and stunted cedars and junipers grow in the sheltered ravines of the "bad lands." Cactus and sage brush in this region are also common.

Climate.—Since there are no mountains, forests or large bodies of water to have a moderating effect, the climate is strikingly uniform over various portions of the State. Great extremes of temperature are likely to be encountered in any part of the State, but the dryness of the atmosphere makes them easier to bear. The seasons are sharply demarked; both winter and summer come rapidly. The summers are short, but long hours of sunlight make the vegetation grow rapidly. Killing frosts sometimes occur in May and return again in September. High winds are frequent and prairie houses are protected by rows of trees planted as "wind breaks." Tornadoes are not unknown, and hail storms are frequent in summer. During the growing season the winds are usually light; but in the late summer occasional dry, hot winds from the south prove very destructive to crops. The average rainfall for the State is 18 in. and is well distributed, but generally decreases east to west from 22 in. in the Red river valley to about 14 in. along the western boundary. While below normal for humid regions, the greater part of the rain comes in the spring and summer so that the crops receive full benefit. The snows are light, and the prairies are often swept bare by high winds so that cattle may graze throughout the winter.

Government.—The State is governed under its Constitution of 1889, as subsequently amended. Previous to 1918 the Constitution required that a proposed amendment pass two successive legislatures before it could be submitted to the people for ratification, but in that year the 28th amendment made it necessary that it pass but one. This amendment also gave the voters of the State the power of proposing amendments by an initiative petition which must be signed by 20,000 voters before the amendment can be voted upon. Another amendment in 1918 gave the voters power to initiate legislation (the initiative petition to require the signature of 10,000 voters), and the power of referendum (the referendum petition to require the signature of 7,000 voters). The veto power

of the governor does not extend to measures initiated or referred to the electors and thereupon passed. Amendment 33 gave the electors the power of recalling any elective congressional, State, county, judicial or legislative official, the recall petition to contain the signatures of at least 30% of the voters voting at the preceding election. The legislative assembly of the State is composed of a senate and a house of representatives with a member-

PROPORTION OF FARM LANDS IN NORTH DAKOTA, 1900-1925

ship respectively in 1927, of 49 and 113 members. Senators are elected for four years and representatives for two years. The assembly meets the first Tuesday after the first Monday in January in odd-numbered years.

The executive officers who are elected are the governor, lieutenant governor, secretary of State, auditor, treasurer, attorney general, commissioner of insurance, commissioner of agriculture and labour, superintendent of public instruction and three railroad commissioners, all serving a two-year term. The executive department includes some 50 boards or commissions whose members are partly elected officials, whose service on these boards is part of their *ex-officio* duties, and partly officials appointed by the governor. The governor appoints a tax commissioner, adjutant general, State engineer, State mine inspector, State examiner, three members of the board of administration (into which the board of control, board of regents and board of education were merged in 1921) and members of many professional examining boards. Since 1919 when the industrial programme of the Non-partisan League was put into operation, one of the most important boards, composed of the governor, commissioner of agriculture and labour and the secretary of State, has been the industrial commission, which has the management of State industries and enterprises, including the Bank of North Dakota and the North Dakota Mill and Elevator, in its hands.

The supreme court of the State, having appellate jurisdiction only, is composed of five justices elected for six years each. A term is held on the first Tuesday of every month in the year, except July and August. There are six judicial districts in the State. The 1st, 2nd and 6th have three justices each, while the others have but two each, all elected for a term of four years. There are probate courts in each county, and justices of the peace in each township and village. Some cities are provided with police courts.

Population.—With homesteaders spreading over the prairies, the population increased from 36,909 in 1880 to 190,983 in 1890. 319,146 in 1900, 577,056 in 1910 and 646,872 in 1920. The influx then halted, the 1925 census showing but 641,192 inhabitants. The density per square mile was 9.2 in 1920. Of the total population in 1920, 98.9% was white. Indians numbered 6,254 or almost 1%, while negroes numbered 467 or 0.1%. The Indians belong

mainly to five tribes, the Chippewa living in the Turtle mountains, the Mandan, Gros Ventre or Hidatsa, the Arikara tribes at the Ft. Berthold agency, and the Sioux, or Dakota, at Devils lake and Standing Rock agencies. Of the white population in 1920 131,503 or 20.5% were foreign-born. The most important countries of origin represented were Norway, 38,190; Russia, 29,617; Canada, 15,550; Germany, 11,960; Sweden, 10,543 and Denmark, 4,552. Of the 79.5% native-born, 31.9% are of foreign parentage and 15.1% of mixed parentage—percentages greater than in any other State of the Union.

Of the total population but 88,239 were inhabitants of cities of 2,500 or over. This urban percentage of 13.6 is lower than in any other State except Mississippi, and shows how pre-eminent are the agricultural interests of the State. Bismarck, the capital city, had a population in 1925 of 9,150, an increase of 2,038 over 1920. Fargo, the chief city, numbered 24,921 inhabitants in 1925 while the other cities of importance and their population in the same year were: Grand Forks, 15,168; Minot, 12,245; Jamestown, 7,230; Devils Lake, 5,409; and Mandan 5,068.

Finance.—The gross wealth of North Dakota was estimated by the Federal Census Bureau at \$2,467,300,300 in 1922. In its per caput wealth of \$3,692 the State ranked seventh among the States. The assessed valuation of property in 1928 amounted to \$1,323,038,508. Real estate composed 72.52%, live stock 3.55%, farm implements and machinery 2.09%, manufacturing machinery and tools .09% of the assessment valuation. All structures and improvements on farms are exempt from taxation but, nevertheless, farm property paid approximately 62% of all taxes levied in 1927. On the 1926 valuation a total of \$29,165,310 in direct taxes was levied, 14.49% by the State, 22.95% by counties, 8.13% by townships, 46.21% by school districts and 8.22% by cities and villages. Besides the general property tax an increasing amount is collected by special taxes. An inheritance tax law was enacted in 1913, a motor vehicle licence tax in 1917, income, gasoline taxes and a gross earnings tax on car companies in 1919 and a cigarette tax in 1925. The income from special taxes in 1928 was \$4,372,218. The total tax burden in 1925 amounted to \$49.63 per caput, a decrease from \$54.17 per caput in 1921.

Receipts of the State Government in the fiscal year 1927-28 amounted to \$35,134,694, while expenditures were \$21,719,565. On June 30, 1928, the total outstanding State debt was \$34,857,500. Approximately \$28,000,000 of this was in the form of rural credit bonds, the proceeds of which were loaned in turn to the farmers. These bonds are secured in all cases by first mortgages and the State only stands as surety for their payment. Aside from the rural credit bonds the State has bonds for \$6,500,000 used to construct and finance its various industrial enterprises, notably the Bank of North Dakota and the State Mill and Terminal Elevator. If these enterprises become a financial success they will retire their own bonds and taxes for the purpose will not be necessary.

There were, Oct. 30, 1928, 134 national banks, 348 State banks and 3 trust companies. Their total resources and liabilities amounted to \$175,883,104; loans and discounts to \$92,543,647; capital, surplus and undivided profits to \$17,414,707. Of the \$147,106,336 deposits \$45,152,920 were in savings accounts.

Education.—Public schools of secondary rank are under the control of the State department of public instruction, while the State institutions of higher learning are supervised by the State board of administration.

In the secondary school system of North Dakota there were, in 1928 4,357 one-roomed schools, 199 consolidated rural schools of more than one room and 533 graded schools in towns or cities. In the school year ending in June, 1928, there were 172,539 pupils

GRAPH SHOWING GROWTH OF POPULATION IN NORTH DAKOTA, 1860-1925

enrolled, of which 69,526 were in rural one-roomed schools, 9,911 in rural schools of more than one room and 93,102 in city and town schools. The number of teachers in the public schools was 8,380, of whom 4,808 were employed in country schools. The average monthly wage paid to those in rural one-roomed schools was \$86.76 and to those in city and town schools, \$133.40. The high school enrolment was 26,820 in 1927. The total revenue for the public school system amounted to \$23,278,408 in the year ending in June, 1928, of which \$12,152,072 or 52% was raised by local district taxes. The educational cost per pupil averaged \$9.41 a month for the school year.

The University of North Dakota, with 2,608 students and 160 teachers in 1928, is situated at Grand Forks and composed of a college of liberal arts, schools of education, law, engineering, medicine and commerce, a graduate division and an extension division. The State Agricultural college at Fargo had, in 1927-28, 2,057 students regularly enrolled. There are State teachers' colleges at Valley City, Mayville and Minot, all giving four years of college work, with an enrolment in 1927-28 of 2,047, 1,015 and 1,832 students respectively. A State normal school at Dickinson had an enrolment in 1927-28 of 751 while the State normal and industrial school at Ellendale registered 644 students. At Wahpeton is a State school of science, which operates as a trade school and junior college, giving instruction in the electrical trades, plumbing, bricklaying, printing, auto mechanics, dressmaking and business courses. The State school of forestry is at Bottineau and gives work of a junior college grade.

There were but two private institutions of higher learning in 1926-27, Jamestown college at Jamestown, and Wesley college at Grand Forks. All institutions of higher learning, both public and private, in North Dakota are co-educational.

Charities and Corrections.—The State board of administration has general control over a State penitentiary situated at Bismarck, a hospital for the insane at Jamestown, an institution for the feeble-minded at Grafton, a State training school at Mandan, a school for the deaf at Devils Lake, a school for the blind at Bathgate and a State tuberculosis sanatorium at Sun Haven, Dunseith. There is a soldiers' home at Lisbon which is not under the control of the board. There is a State children's bureau which licenses and regulates hospitals and lying-in-places which receive maternal cases and institutions which receive children for temporary or permanent care. The bureau investigates homes into which children are placed for care or adoption, and co-operates with the juvenile courts in investigation of delinquents, with the county commissioners in administering the mother's pension law, and in general works to enforce the child labour and all other laws relating to abuse or neglect of children.

Agriculture and Live Stock.—Probably no other State in the Union depends so exclusively upon agriculture as a means of livelihood as does North Dakota. Of its total area 76.4%, or 34,327,410 ac. is classified as farm land. Of its population 58.2% (exceeded only in Mississippi) actually live on farms, and the

PROPORTION OF TOTAL UNITED STATES CROPS OF CERTAIN GRAINS RAISED IN NORTH DAKOTA, 1927

population of the small towns is almost entirely dependent upon farm trade for its support. The value of all crops was estimated in 1919 at \$286,249,403, in 1924 at \$358,200,000 and in 1927 at \$274,700,000, 1924 representing an unusually good year and 1927 an average one. The value of live stock upon farms amounted to \$157,034,635 in 1920 and \$94,302,899 in 1925. All farm property was valued in 1925 at \$1,191,036,966, a decrease of about \$570,000,000 from the inflated valuation of 1920. The decrease was due mainly to the decrease in value of land from an average of \$35.33 per acre in 1920 to \$23.70 in 1925. The hardships suffered

during the period of agricultural depression were represented in a decrease of farm population from 394,500 in 1920 to 372,886 in 1925 and a decrease in the number of farms operated by owners from 56,917 to 49,513. Of the latter 63.8% in 1925 were reported mortgaged, the average debt being \$5,284.

North Dakota is divided into three very distinct farming belts. The black-earth belt occupies nearly half the State covering all east of a line drawn from the southern boundary at Dickey county north-westward to Rolette county on the Canadian border, and also including a small area in Divide and Burke counties in the north-west. In this zone the soils are dark, moisture conditions are favourable, production is the highest for the leading crops and the size of farms (averaging 480 ac.) is generally smaller than in other parts of the State. West of the black-earth belt, extending a short distance west of the Missouri river and including also the greater part of McHenry and Bottineau counties to the north is the farming-grazing belt. This is, in general, rougher in topography with soils somewhat lighter and production about 20% lower than in the black-earth belt. The average size of farms in this division is 640 acres. In the south-western quarter of the State is the grazing-forage crop belt. The region is hilly, the soils are residual in origin and the rainfall is less than in other parts of the State. The size of farms in this section averages 800 ac. and less than 30% of the farm land is devoted to crop production.

The main crop of North Dakota is wheat in the production of which the State ranked first among the States in 1925 and second in 1927 with 112,387,000 and 94,268,205 bu. respectively. Its value for 1925 and 1927 was \$147,215,000 and \$125,973,000. Slightly less than 50% of the crop area of the State was devoted to this crop, varying from 35 to 42% of the acreage in the east to 60% in the west. North Dakota wheat has a high protein and gluten content and commands a premium in the market. Oats in 1927 occupied about 9% of the crop area, being somewhat more important in the northern than in the southern part of the State. The value of the crop was \$34,408,000 in 1926 and \$16,990,000 in 1927. About 8% of the crop area in 1926 was devoted to barley, in the production of which the State ranked first in 1925 and third in 1926. Its value in 1927 was \$25,020,000. In the growing of rye North Dakota leads all States with a production in 1925 nearly triple, and in 1926 almost double, that of its nearest competitor. In 1927 14,047,000 bu. with a value of \$18,450,000 were harvested. North Dakota also led in the production of flax in 1927 with a crop valued at \$18,379,000. Indian corn showed marked increase in acreage from 1920 to 1924 but decreased slightly in 1926 and 1927. In the latter year 959,000 ac. produced 23,975,000 bu. valued at \$14,864,000. It is relatively more important in the south-eastern portion of the State together with an area in Burleigh and Morton counties. Tame hay occupied about 5% of the crop area and was relatively more important in the western and south-western parts of the State. A great amount of wild hay is also harvested, the value of the latter in 1927 being \$8,670,000 and the former \$15,155,000. Potatoes are generally of excellent quality. In 1927 7,045,993 bu., valued at \$5,763,000, were raised. The average yield per acre for the leading grains during a period extending from 1909 to 1928 was approximately as follows: Indian corn 25 bu., wheat 17 bu., oats 26 bu., barley 20 bu., rye 13 bushels. Deficient moisture is the most important cause of damage to grain, especially in central and south-western North Dakota, while in the south-east wheat is subject to rust.

The raising of grain is supplemented on most farms by the raising of live stock. This becomes the major industry in the grazing-forage belt south-west of the Missouri. Beef cattle, sheep and horses are found in increasing numbers from east to west across the State. Swine are found mainly in the south-east where a large proportion of the corn is raised. They numbered 652,000 in 1928 valued at \$26,064,000. Dairying showed a vigorous growth between 1916 and 1927, the number of dairy cows increasing from 221,016 to 365,038. The amount of butter made in creameries increased from 3,210,767 lb. to 33,934,625 lb. and the amount of butterfat marketed through cream stations from 5,777,687 lb. to 31,668,990 pounds. The beef cattle business was slow in recovering from the depression following the World War but there

was a notable improvement in 1927. Sheep showed a quicker recovery than any other branch of the live stock business, the number increasing from 203,000 in 1922 to 399,000 in 1925 and their value from \$945,000 to \$4,074,000. Wool production in 1926 amounted to 2,772,000 lb., or 8.3 lb. per fleece.

Mining.—North Dakota is not a metal-producing State, but it possesses extensive coal and clay deposits which are sure to become more widely developed and prove of great economic value.

Lignite coal deposits of varying thickness underlie no less than 32,000 sq.m. of surface in the western half of the State. The U.S. Geological Survey estimates that of total lignite deposits of 965,902 million tons in the United States 633,329 million are in North Dakota, and about 500,000 million are capable of being mined. Beds 6 to 8 ft. thick are common. In places they lie so close to the surface that the overlying soil can be stripped and the coal mined in open cuts; in other places the room and pillar method is used. In 1927 there were 231 mines in operation of which 146 were underground. The coal output amounted to 1,529,154 tons valued at \$2,762,000. The increase in production is shown by comparison with 416,580 tons in 1910 and 878,969 tons in 1920. An economically practicable briquetting process has been perfected which doubles the heat value of the coal, makes it less liable to deterioration and more convenient to handle.

Clay is found in a large number of varieties ranging from common brick through tile to high grade art pottery clay. Deposits are large especially in the western part of the State where they are found near lignite beds, a proximity which enhances the value of both. Clay products in 1927 were valued at \$150,000. The great gravel deposits of the State, found mainly in the ridges of glacial moraines, are becoming increasingly important with the construction of modern highways.

Manufactures.—Though in 1925 North Dakota had less manufacturing than any other State except New Mexico and Nevada, this branch of industry was showing a rapid growth. There were then 320 establishments employing 3,261 wage-earners and producing products valued at \$44,631,516. The most important products were those closely connected with agriculture, namely, butter, cheese, condensed and evaporated milk products to the value of \$14,786,842 and flour, feed and other grain products to the value of \$16,052,922.

Transportation.—The State is crossed east and west its entire length by two transcontinental railways, the Great Northern and the Northern Pacific. Another transcontinental line, the Chicago, Milwaukee and St. Paul cuts across the south-western corner, while the St. Paul and Sault Ste. Marie runs from the south-west corner diagonally north-westward to make a transcontinental connection with the Canadian Pacific at the Canadian border. Branches of these main lines intersect the wheat-raising areas in every direction. The railroad mileage increased from 4,201 in 1910 to 5,311 in 1920 but fell to 5,284 in 1927.

There were in 1928 106,498 m. of rural roads and 7,500 m. in the State highway system. Of the latter about one-half was earth graded and provided with drainage and 1,980 m. were surfaced with gravel. Motor vehicles registered increased from 24,908 in 1915 to 90,840 in 1920 and 160,978 in 1927.

History.—Frenchmen of an expedition led by Pierre de la Verendrye crossed from the Assiniboine river in Canada to the Missouri river in 1738 searching for a "river to the west" and were probably the first Europeans in North Dakota. Two of Verendrye's sons returned in 1842 on the same mission but after months of wandering in the region south-west of the Missouri they also were forced to give up their quest and return. After 1790 this journey overland from the Assiniboine to the Missouri became common, parties of traders making the visit nearly every year to trade with the Indians for furs. Also after 1790 penetration of the Red river valley in eastern North Dakota was commenced by North-west and Hudson bay traders. Charles Chaboillez in 1797 established the first North Dakota trading post on the Pembina river near its junction with Red river, but it was soon abandoned. Alexander Henry, Jr. built a post in 1800 near the mouth of Park river which he occupied until 1808, and shortly after John Cameron built a post on the site of the present East

Grand Forks.

After North Dakota, as a part of Louisiana territory, was acquired by the United States in 1803, exploration by that country commenced. The first Government expedition was that by Lewis and Clark which ascended the Missouri in 1804 and spent the winter at the Five Villages of the Mandan and Hidatsa tribes, pressing onward into Montana in the spring of 1805. Their return in 1806 stimulated the interest of St. Louis fur traders in the region, one of whom, Manuel Lisa, ascended the river in 1807 and opened trade relations with the Missouri Indians. His traders or those of his rivals thereafter ascended the river annually.

All of the tribes of Dakota were now in touch with the white man and the next 50 years, 1820-70, is largely a story of the fur trade, and of the attempts of various companies to secure themselves against the encroachments of their rivals. Despite the Treaty of Paris in 1813 which established the international boundary at the 49th parallel, the British long maintained their influence among the Indians of lower Red river valley, the Mouse river and Turtle mountain regions. On the Missouri the trade, after 1828, was monopolized by the American Fur company which built Ft. Clark at the mouth of Knife river, Ft. Union near the mouth of the Yellowstone and in 1831 introduced the steamboat on Missouri waters. The Columbia Fur Company also established a number of posts from the Red river to the Missouri but was forced to sell out to the American Fur Company in 1827.

The first genuine settlement of home-seekers in North Dakota in this period was made by a band of settlers from Lord Selkirk's colony of Scottish Highlanders in Manitoba who migrated south of the boundary line and settled at Pembina in 1819. When Maj. Stephen H. Long, leading the first United States exploring expedition into the Red River valley in 1823, visited the place, the population numbered 600. Communication was soon established and trade opened between this colony and American settlements at Ft. Snelling and Prairie du Chien on the upper Mississippi river. Cattle and seeds were brought in, and cartloads of furs were yearly sent out. Year by year commerce over this Red river trail increased in importance. Ft. Abercrombie was built in 1858 and became a rendezvous for commercial and military operations in the north-west, as well as a rallying point for settlers.

Between 1850 and 1870 there was considerable difficulty with the Dakota Indians, whose lands in Minnesota had been largely appropriated by the whites, and whose buffalo herds on the Dakota prairies were fast being depleted by the hunting activities of traders and half-breeds. The Minnesota outbreak of 1862 was followed by campaigns by Gens. Sibley and Sully in 1863 and 1864 which finally drove the hostile Dakotas to the "Bad lands" west of the Missouri river. All eastern North Dakota was now open for occupation and the completion of the first railroad to the eastern border in 1871 inaugurated the settlement period in earnest.

The following decade was a period of intensive development in the Red River valley, and by 1880 settlement was spreading out over the area of the drift plain, especially along the line of the Northern Pacific railway which in 1873 had reached the Missouri river at Bismarck. West of the Missouri the country was made safe for cattle-raising by the Indian campaign of 1876-91 which finally broke the power of the Dakota tribes. The completion of the Great Northern railway across the northern part of the State in 1887 opened that region to eager settlers. The region forming North and South Dakota, which since 1861 had been known merely as Dakota Territory was divided in 1889 into a northern and southern half. A convention met in North Dakota in July and framed a Constitution which was accepted by the people in an election held on Oct. 1. President Harrison declared the State's admission to the Union on Nov. 2, 1889.

The years 1890-1915 were years of constant growth in population and intensive railroad development. Competing railway lines strove to forestall each other in tapping promising grain territory. Once there they did their best to bring settlers into the newly opened region by conducting land excursions. Nearly 18,000 immigrants annually for this span of years made new homes in the State. Settlement of the drift plain was practically completed and

homesteaders invaded the good land beyond the Missouri river. The rush continued with little abatement until the World War, after which, because of the general depression in agriculture, it practically ceased.

In politics North Dakota is normally Republican but its farmers have shown a tendency to desert the party in times of agricultural depression for third parties which usually promise more direct and radical remedies. In 1912 North Dakota, holding the first presidential primary election in the United States, showed its preference for La Follette. Resentment which had been gathering for a number of years against constant and wholesale abuses in grading and marketing grain resulted in 1915 in the formation of the Non-partisan League (*q.v.*), a farmer political organization. This organization was so successful that by 1918 it had elected the governor and a majority of both houses of the legislature and so could carry its programme into operation. An industrial commission was created to manage, operate and control all State-owned industries and business projects created by law, and three major enterprises were established, namely: a Bank of North Dakota, a State-owned and State-operated Mill and Elevator, and a Home Builders' Association. The conservative element was able, in an election in 1921, to muster strength enough to recall the members of the industrial commission; but constitutional amendments and initiated laws, proposed at this election with the intention of overturning the league programme, were defeated, and in 1928 all league enterprises, excepting the Home Builders' Association, were still in operation.

BIBLIOGRAPHY.—For official information about the State and its activities the reports of the various departments, commissions and bureaux furnish the most complete figures and facts. This information is also found in the volumes of *Public Documents* and the *Blue Book*. For the general history of the State the most important reference works are the *Collections of the State Historical Society of North Dakota* (1906 seq.); *North Dakota Historical Quarterly* (1926 seq.); *South Dakota Collections* (1902 seq.). Important books are D. E. Willard, *The Story of the Prairies, or Landscape Geology of North Dakota* (1902); W. M. Wemett, *Indians of North Dakota* (1927); R. T. Young, *The Life of Devils' Lake* (1924); A. G. Leonard, E. J. Babcock and L. P. Dove, *Lignite Deposits of North Dakota* (1925); C. L. Young, *Government of North Dakota and the Nation* (1922); J. E. Boyle, *Government of North Dakota* (1922); H. E. Gaston, *The Nonpartisan League* (1920); C. E. Russell, *Story of the Nonpartisan League* (1920); A. A. Bruce, *Non-partisan League* (1921); C. A. Lounsbury, *Early History of North Dakota* (1919); W. M. Wemett, *Story of the Flickertail State* (1923); H. C. Fish and R. M. Black, *Brief History of North Dakota* (1925); L. F. Crawford, *Badland and Broncho Trails* (1922); H. Hagedorn, *Roosevelt in the Bad Lands* (1921); L. A. Lang, *Ranching With Roosevelt* (1926); H. V. Arnold, *History of Old Pembina* (1917). Many valuable articles are found in volumes of the *Quarterly Journal of the University of North Dakota* (1910 seq.).

NORTH DWINA PROVINCE, a unit of the North Eastern region of European Russia, bordered on the west and north by Archangel, on the east and north by the autonomous Komi (Zirian) area, on the south-east by Vyatka, on the south by Nizhniy-Novgorod, on the south-west by Kostroma and on the west by Vologda. It has an area of 106,115 sq.km. and a population (1926) of 678,255, of whom 80% are Great Russians and 18% Zirians. Over 80% of the province is clad with coniferous forest, the cleared areas being mainly along the river banks.

The Dwina and its tributaries, the Sukhona, Yug, Vychegda and Luza, drain the province; the Sukhona is most used for navigation, since it connects via the Württemberg canal both with Leningrad and with the Volga river. There are no bridges except the railway bridge over the Luza river.

Cultivation is most dense in the south, and along the river banks, but, apart from the 80% forest, there is 12.8% of marsh land, so that less than 10% is available for the production of the winter rye, oats, barley, flax and potatoes grown here. There is some meadow and pasture land, and horses, cattle, dairy cattle and pigs are bred, the latter in large numbers. The income from hunting and fishing is small, though the salmon and sterlet of the Dwina river are noted for their quality. Linen is the most important industry and exceeds pre-1914 level, as does production of hemp and jute rope.

In addition to river communications, the railway from Vyatka

reaches Kotlas (*q.v.*), which has wharves and grain elevators, and from which the railway is to be continued to Soroka on the Gulf of Omega, thus providing a further outlet for Siberian grain. From Ustyug-Velikiy (*q.v.*), the administrative centre, at the junction of the Sukhona and Yug, post roads, impassable in spring and autumn, go to Vologda and Nizhniy-Novgorod, and the town has telegraphic links with the south and also as far north as Krasnoborsk. Electrification proceeds rather slowly, though the few town centres have production plants. The peat reserves in the region should prove an asset in the future. The province needs much more intensive colonisation for its full development.

See M. I. Ivanovskiy, *The North Eastern Area* (1926) (in Russian).

NORTHERN AUSTRALIA, a term indefinite but applied generally to that portion of the continent which lies north of the Tropic of Capricorn (*c.* 1,150,000 sq. miles = 0.386 or about $\frac{1}{8}$ of the whole territory), comprises the northern portions of Western Australia (364,000 sq. miles = 0.373 of the State), of the (former) Northern Territory (426,320 sq. miles = 0.814) and of Queensland (359,000 sq. miles = 0.535). Except for a practically continuous belt of coastal lowlands—broader along and up the river valleys of the north-west and north and around the Gulf of Carpentaria (*q.v.*), narrow to the point of disappearance along the north-east—almost the whole of this area consists of tablelands of 500–1,500 ft. general elevation with but few small and isolated higher areas in the west, north-west, north-east and central south. (See AUSTRALIA: *Geomorphology*.) Climate is thus the dominant factor and characteristic in this respect are prevailingly high temperature levels, 85°–70° F (*c.* 60° in the central interior) and summer (monsoonal) rainfall: *c.* 60 in. along the north, sinking to 20 in. at about 18° lat. and to 10 in. and less farther inland. Thus, apart from the mineral wealth, of which a probably small part has so far been exploited, the chief economic possibilities would appear to be pastoral development in the drier and more invigorating interior, tropical agriculture in the more humid lowlands and fishing—including pearl-oyster, etc., fishing (see BARRIER REEF)—around the coasts. The ultimate commercial and strategic importance of certain parts of the coasts are probably also considerable.

The regional differentiation inherent in so vast an area will increasingly invalidate generalisations about it and the tropical portions of Queensland and Western Australia are best dealt with under those States (*qq.v.*). The area which was till recently called the Northern Territory is on a somewhat different basis, and as it also offers a fair average "cross-section" of northern Australia, a brief account of it is given here.

The area in question extends from the Western Australian to the Queensland border (Longs. 129°–138° E.) and from the north coast—including adjacent islands, *e.g.*, Melville, Bathurst, Groote Eylandt—to the South Australian border (26° S. lat.) and covers 523,620 square miles in all. After a chequered history it was handed over by South Australia to the Commonwealth in 1911, and, as a result of further and on the whole unsuccessful experience, it was subdivided—in March, 1927, under the "Northern Australia Act" of 1926—into North Australia and Central Australia, lying respectively north and south of lat. 20° S., to be administered, from Newcastle Waters and Alice Springs (*q.v.*) respectively, as Commonwealth territories, each by a Government Resident assisted by an Advisory Council of four.

North Australia (287,056 sq. miles) consists mainly of rolling country which rises from the coastal lowlands and valleys to a general level of 500–1,000 ft. inland. In the north is the rather higher (sandstone) tableland of Arnhem Land and on the east and west the land rises gradually to the Barkly Tableland and the Kimberley plateau respectively. In the south the swell of the land forms (17°–20° S. lat.) an almost imperceptible watershed between the coastwards and inwards-flowing drainage. The coast is mostly low, sand-beaches and mangrove mud-swamps alternating with cliffy bluffs, but some fine natural harbours ("drowned" river-mouths) exist (*cf.* Port Darwin). There are two seasons, the wet (Nov.–May) and the dry, and the average ann. rainfall ranges from *c.* 40 in. in the north (Darwin: 62 in.) to 14 in. in the south. Temperatures are high, but the range is greater, the heat is

drier and more bearable, and the winters are cooler towards the south (Darwin, av. ann. temp., 85.7°–77.2° F; Daly Waters [300 miles inland], 88.2°–68.6° F [*cf.* Alice Springs *inf.*]). In the wet season the streams are mostly swollen, swift and liable to flood and wide areas in the valley bottoms are then under water while inland are lagoons and swamps (Lakes Woods, de Burgh, etc.). The Victoria, Daly, Roper and McArthur are considerable streams but are normally navigable only in the dry season for small craft (4 ft. 6 in. draught; cargo capacity 35 tons). The valleys are often timbered and open forests occur in parts, but the prevailing vegetation is of the savanna type—grass with scattered trees—merging inland into poorer scrub with soft spinifex in the sandy south-western corner. From Camooweal (Queensland) to Newcastle Waters, in the upper Victoria River basin, and also south-westwards towards Hall's Creek (Western Australia) are broad belts and patches ("many thousands of square miles") of open black-soil (limestone and volcanic) plains bearing first-class fodder grasses (Mitchell, Flinders, etc.) and edible scrubs and here are the principal cattle stations (*e.g.*, Alexandra, Anthony's Lagoon, etc., on the Barkly Tableland; Wave Hill, etc., on the Victoria River). Surrounding these and occupying the bulk of the central belt are great expanses of more mixed country, fairly well grassed and watered and containing good patches. The sandy plateaux of the north and of the coastal margins have many well-grassed valleys and the swampy flats mentioned above. Lateritic and travertine incrustations, products of climatic and soil conditions, render considerable areas unproductive. Water is, generally speaking, available on the surface or in underground supplies and minerals are known to be widely distributed. The chief economic potentialities have been indicated. Efforts towards development have not hitherto been conspicuously successful and a summary of the present (1927) economic and social position will suffice.

Population: Europeans, *c.* 2,300; non-Europeans (mainly Asiatics) 1,050; aboriginals, 20,000. **Land Tenure:** Of the total area *c.* 750 sq. miles have been alienated, *c.* 8,000 sq. miles have been reserved for aboriginals and 1,025 for mission stations, while 160,850 sq. miles are leased for pastoral purposes, nearly one-half (or *c.* $\frac{1}{4}$ of the whole of North Australia) of which is held by six lessees. **Stock** (including Central Australia): cattle, 778,000; horses, 27,800; goats, 12,500; and sheep, donkeys, mules, camels, etc. (Cattle and horses do well; sheep do best on the Barkly Tableland.)

Products:—**Minerals:** output, £16,900 (tin concentrates—mainly Marranboy field—98 tons: £15,800), besides gold, silver-lead, etc. **Fisheries:** Pearl-shell (63 tons): £11,500, besides small quantities of other products. **Nuts and Grains:** ground-nuts (peanuts), cotton, and millet are grown. Coconuts are being cultivated. **Trade:** Exports: cattle and cattle products, £103,500 (Darwin exports £29,800, mainly cattle to Manila; this trade in cattle has since been discontinued). Imports £36,800. **Communications:** **Railways** (3 ft. 6 in. gauge), from Darwin to Emungalan (199 miles), now being extended to Daly Waters (360 miles). **Bush tracks:** *c.* 3,500 miles. **Telegraph and Cables:** Darwin overland line southwards (to Adelaide), also cables (3 lines) to Java, Singapore, etc. **Wireless:** Darwin and various cattle stations. **Steamer:** Darwin to eastern (Australian) States, monthly; to Western Australia, every two months. **Inland mail services:** 6-weekly (pack horse).

General Social and Economic Conditions.—Isolation, lack of communications, pioneering conditions, climatic influences have contributed to social and political unrest, lack of balance, and of continuity and stability. Wages have been high, labour scarce and exacting, much effort and expenditure has produced small results. The total cost of the Northern Territory to the Commonwealth (1911–1926) was nearly £9,000,000, including deficits taken over from South Australia (*c.* £4,000,000). Climatic difficulties, though serious, do not appear insuperable, but more attention must be devoted to hygiene (housing, ventilation, diet, etc.) and to economic adjustments and adaptations (*e.g.*, morning and evening hours of work).

Darwin (pop. *c.* 1,400), the temporary seat of the administration, is well built and well laid-out with wide streets, has stone

buildings and amenities (Botanic Gardens, etc.) and a natural harbour capable of improvement. The recently appointed Northern Australian Commission, as a result of careful and dispassionate investigation, report (Dec. 1927): "The reason that North Australia is not more developed than it is to-day is . . . certainly not attributable to a lack of natural resources. . . . Portions of the other States . . . which are now thriving centres, had not, as a foundation, country of as good a class. . . . It is regrettable that people, many of whom are not competent to express an opinion, . . . should decry (it)." There is now hope that a policy of sober, scientific, and consistent development is being inaugurated. It is significant that the first recommendations of the Commission should be directed towards the improvement of communications—railways—particularly the linking of the Darwin-Daly Waters line with the Queensland system via Camooweal—motor roads, stock-routes, ports—notably a port on the Gulf coast at the Sir Edward Pellew Islands to serve the Barkly Tableland and farther interior—besides increased telegraphic, wireless, aerial, and coastal shipping services; towards improved water supply, and hygienic and social facilities (e.g., broadcasting), and towards the initiation of organised scientific research. (See also CARPENTARIA, GULF OF.)

Central Australia (236,400 sq. miles) is an oblong area lying between latitudes 20° S. and 26° S. and longitudes 129° E. and 138° E. The flat-lying sediments (sandstones, etc.) which were the floor of an ancient (Mesozoic) sea were subsequently elevated and denuded and now form a plateau, highest (c. 2,000 ft.) in the centre and sloping down gently eastwards and south-eastwards to the Eyre-Diamantina basin in Queensland and South Australia. In the north an extension of the West Australian "platform" stretches eastwards. (Cf. Murchison and Davenport "ranges," c. 1,000 ft.) Across the centre lie the Macdonnell Ranges (Mount Heughlin, 4,800 ft.), a series of parallel ridges and troughs composed partly of hard folded (Palaeozoic) rocks, the uptilted edges of the above-mentioned plateau. The main drainage lines originate amidst, and north of, the Macdonnell Range and run south-east (Finke, Todd, etc.) towards Lake Eyre. These streams, during a former rainier epoch, incised their courses to keep pace with the uplift (*v. sup.*) and have seen through the hard ridges remarkable transverse gorges valuable because of the facilities they offer for routeways and for the impounding of water. To-day the beds contain streams only after rains, the lower courses being normally long tree-lined tracks of water-bearing sand and gravel. The climate is transitional between that of northern and southern Australia and shows continental extremes (Alice Springs [alt. 2,000 ft.]: av. ann. temps. 84°–52.5° F with cool and bracing winters; rainfall occurs throughout the year with summer maximum and variations from 28.5 in. to 5 in.). Mainly steppe country with sparse scrub (mulga, etc.), low scattered growths, and grass in good seasons, the earth lies bare and dust-swept in times of drought except where stream-courses, soaks, and water-holes afford a little moisture. Clay and stone desert patches occur and in the little-known north-west and south-west, and again in the east, are areas of sandridge, spinifex, saline flats (Lake Amadeus), and some scrub. In the more humid north-west are areas of seasonal swamp. (Cf. North Australia.) After rains the country is transformed as by magic; flowery grasslands spread like seas to the horizon, streams and pools sparkle, life awakens and flourishes for a space. Apart from a little agriculture for home needs—some of it possibly by irrigation—the economic future seems to lie mostly in the direction of pastoralism and mining. Minerals—gold (e.g., Arltunga), mica, nitrates—a recent discovery—exist, the mica deposits being particularly valuable. Erratic rainfall, rabbits and dingoes are the bane of the pastoralist and little stability can be obtained until water-resources—superficial and underground—have been tested and supplies assured. Some 76,000 sq. miles have been let under pastoral leases or grazing licences but as in North Australia the conditions of land tenure seem to need revision. Given water—horses, sheep, cattle, and live stock generally thrive, as do also human beings, in the climate. (Live stock: c. 117,000 head—including 85,000 cattle, 15,000 horses.) But costs of all necessities—including fencing and mining

machinery—have been prohibitive. Transport has been by camel, horse or mule train, but motor traction is possible and is increasing. The overland telegraph line traverses the heart of the area and along it—with its Government wells—lies the chief route for stock and men. Apart, too, from a few mining, cattle, and mission stations and blacks' encampments, practically all the population (Whites: c. 410; aboriginals: c. 4,000) lives in telegraph stations along this route. The railway line (3 ft. 6 in. gauge) from Oodnadatta (South Australia) is under construction and this will bring Alice Springs (*q.v.*) within 60 hours (c. 1,000 miles) of Adelaide. Another line may ultimately be built from Alice Springs to the proposed port at the Sir Edward Pellew Islands (Carpentaria, Gulf of, *q.v.*) thus giving the area a northern outlet as well. Central Australia should not be regarded as a desert. With improved conditions of water-supply, transport, fencing (against dingoes, etc.), and land tenure its stock-holding capacity, though it will never be high, will probably be very considerable in the aggregate. In particular new sheep areas await development here and facilities for movement (railways, stock-routes, etc.) will help to combat drought. The mineral wealth is a further asset and when social amenities improve, Central Australia will prove a far from negligible national possession.

NORTHERN PACIFIC RAILWAY. The main line of the Northern Pacific Railway extends from Ashland, Wis., United States, through the States of Minnesota, North Dakota, Montana, Idaho, Washington and Oregon, to Seattle and Tacoma in Washington and to Portland, Oregon. Its main terminals in the east are St. Paul, Minneapolis, Duluth and Superior; in the west, Seattle, Portland and Tacoma. It was constructed under an Act of Congress approved by President Lincoln on July 2, 1864. With its completion in 1883 the vast territory adjacent to it was first made accessible to settlers, and the Government's long-cherished aim of opening to the North Pacific coast a route following, roughly, that taken by the explorers Lewis and Clark in their expedition of 1804–06, was at length realized.

The Northern Pacific system consisted in 1928 of about 6,750 m. of operated railroad. It owned also nearly one-half of the stock of the Chicago, Burlington and Quincy Railroad company, and exactly one-half of the stock and bonds of the Spokane, Portland and Seattle Railway company, operating together 11,000 m. additional. A large part of the tonnage which it carries consists of the products of agriculture and of the forest; but its traffic is well diversified and its earnings, under normal conditions, are comparatively stable. It has outstanding 2,480,000 shares of stock of a par value of \$100 each. Its bonded indebtedness in 1927 was \$318,000,000. (C. DON.)

NORTHFIELD, a city of Rice county, Minnesota, U.S.A., on the Cannon river 35 m. S. of St. Paul. It is on Federal highway 65, and is served by the Chicago Great Western, the Chicago, Milwaukee, St. Paul and Pacific, the Minneapolis, Northfield and Southern, and the Rock Island railways, and by motor-bus lines. Pop. (1920) 4,023. It is the seat of St. Olaf college (Norwegian Lutheran, 1874) and of Carleton college (Congregational, 1866). The Goodsell Observatory of the latter gives the time to the railroads over a wide area, through signals sent out daily by the radio broadcasting station of the department of physics. Northfield is surrounded by a rich farming and dairying region, where the breeding of Holstein cattle is an important specialty. It was settled in about 1851; named after John W. North, who planned it and several other towns; and chartered as a city in 1875.

NORTHFIELD, a village of Washington county, Vermont, U.S.A., in the Green mountain region, 10 m. S.S.W. of Montpelier; served by the Central Vermont railway. Pop. (1920) 1,916. It is the seat of Norwich University, founded in 1819 at Norwich (Vermont) by Capt. Alden Partridge (1785–1854), who had been a professor in the U.S. Military academy at West Point and its acting superintendent, and who became the first president of the new institution, serving until 1843. In 1866, after a fire had destroyed its buildings at Norwich, the university moved to Northfield. The charter requires "a course of military instruction, both theoretical and practical," and the discipline is military in

form and principle. The enrolment in 1926-27 was 331. This was the pioneer engineering school in the country.

NORTHFLEET, an urban district of Kent, England, on the Thames, 22 m. E. by S. of London by the S.R. Pop. (1921) 15,720. The church of St. Botolph is of Norman foundation, but the nave is Decorated and the chancel Perpendicular, and the tower, having fallen down, was rebuilt in 1628. The church contains a brass of the 14th century. The nave and chancel have undergone modern restoration. Besides chemical manufactures, there are paper mills, iron foundries, rubber works, chalk, lime, cement and brick works, docks and a shipbuilding yard. Swanscombe almost adjoins Northfleet on the south-west. Its name is said to be derived from a camp formed here by the Danish king, Sweyn, and tradition fixes at this spot the meeting between William the Conqueror and the men of Kent, to whom was confirmed the possession of all their ancient privileges.

NORTH HOLLAND, a Netherlands province, lying between the North sea and the Zuider Zee, and bounded southward by the provinces of South Holland and Utrecht. Three of the great new polders (see NETHERLANDS: *Impoldering*) will extend into the Zuider Zee from its eastern shore. The present area, including the islands of Texel, Vlieland and Terschelling, in the West Frisian group, as well as Wieringen, Marken and Urk in the Zuider Zee, is 1,065 sq.m. with pop. (1926) 1,420,098, showing an increase during the 20th century from 905 per sq.m. to 1,334 per sq. mile. Three natural divisions can be recognized: (1) foreshore and sand-dunes, (2) inner dunes and the *geest* grounds, (3) low fens and clay lands. (See NETHERLANDS: *Coast*.) The dunes form a long, smooth, unbroken protection for the other regions, and the absence of deep inlets explains the absence of commercial towns. IJmuiden is a small town and its recent creation was solely dependent on its position at the exit of the artificial North sea canal from Amsterdam. Nevertheless, the broad, gently-sloping, sandy beach is admirable for sea-bathing, and permits the beaching of the characteristic flat-bottomed fishing boats used at Zandvoort and at smaller fishing villages. Bergen aan Zee, Egmond aan Zee and Wijk aan Zee are gay little unconventional resorts, the growing coastal children of the aged parent villages further inland. In the second zone, behind recently planted woods, especially along the margin of the *geest* grounds, from about 5 m. N. of Haarlem to 10 m. S., hyacinths, tulips, narcissi and crocuses, in exact squares of brilliant and varied colours, attract numerous tourists each spring-time, while market gardens provide valuable and continuous products for home and foreign trade.

This part of North Holland was early inhabited and contains many old towns and villages. Some of the most interesting are Haarlem (pop. 89,500), the seat of government of the old counts of Holland, and the scene of the great resistance of 1573—one of the most glorious failures in history. Near to Haarlem are the extensive red brick ruins of Brederode castle, the seat of an old and illustrious family. Nearer to the south border is Bennebroek, the site of a 10th century nunnery. Alkmaar (*i.e.*, all water), (pop. 27,300), though originally belonging to the lowland zone, also has important historical associations, including its personal success against the Spaniards in the Eighty Years' War. Near Alkmaar are Schoorl—a village in the 9th century—Bergen, also of considerable antiquity, Heiloo, stated to be the site of a church built by St. Willibrord in the 8th century, and the villages of Beverwijk and Velsen. Other possessions of the same apostle still remain, while Egmond, near by, was famed for its great abbey. Nearer Helder (pop. 30,000) is Schagen, a flourishing village in the 12th century, a lordship in the 15th, but of no special importance to-day.

The third division comprises much the largest area, that lying at or below sea-level. Considerable land reclamation has been effected. To the north of the former Y (or IJ) the famous Purmer and Beemster lakes were drained in the beginning of the 17th century; but several sea-polders to the north of these were added to the mainland only in the first half of the 19th century. This region is traversed by the 46 m. North Holland canal (1819-25), between Amsterdam and Helder. The Y, formerly an inlet of the Zuider Zee, was drained, and the direct east to west 15 m.

North sea ship canal was cut in its stead (1865-76); in the south, Haarlem lake (72 sq.m.) was drained between 1840 and 1853. The landscape in this lowland division is more typically Dutch than elsewhere. The province is very poor in minerals, consequently cattle-rearing and cheese manufacture (chiefly Edam) are the main industries, but agriculture and even market-gardening are also practised in the heavier clay lands of the polders. Purmerend, the natural focus of the Purmer, Wormer and Beemster polders, with street and canals too narrow to contain the present market-day produce, Alkmaar, the great cheese town with a famous weigh-house, and Enkhuizen, one of the "dead cities" of the Zuider Zee, are the chief market centres. The security offered by the Zuider Zee for trade and fishing was the prime factor in the commercial development of North Holland, and the cities of Medemblik, Enkhuizen, Hoorn, Edam and Monnikendam, though now of little more than local importance, possessed a large foreign commerce in the 16th and 17th centuries. This prosperity later concentrated itself upon the Y (that is, upon Amsterdam, *q.v.*) and upon the series of industrial settlements situated on its off-shoot, the Zaan, of which Zaandam (pop. 30,000, with oil, saw, corn, cement and paper mills) is the most important.

Of the islands: Marken is rapidly learning how to commercialize its own quaintness, though it is not yet entirely spoiled; microscopic Urk has a population (about 3,000) largely dependent on the North sea fishery. Texel is noted for sheep and their products: wool and green cheese, and also for sea-birds' eggs, which are exported to Amsterdam. Vlieland and Terschelling are but slightly populated and relatively unimportant.

NORTHINGTON, ROBERT HENLEY, 1ST EARL OF (c. 1708-1772), lord chancellor of England, was the second son of Anthony Henley, a Whig member of parliament, and a well-known wit and writer. Robert was educated at Westminster school and St. John's college, Oxford; and was called to the bar in 1732. In 1747 he was elected member of parliament for Bath, of which he became recorder in 1751. He acquired a lucrative practice at the bar, and in 1756 was appointed attorney-general. In the following year he was promoted to the office of lord keeper of the great seal, being the last person so designated. For three years he presided over the House of Lords as a commoner, having incurred the hostility of George II. He was given the title of Baron Henley in 1760 so that he could preside at the trial of Earl Ferrers for murder. On the accession of George III. the office of lord chancellor was conferred on Henley, and in 1764 he was created earl of Northington. In 1765 he presided at the trial of Lord Byron for killing William Chaworth in a duel. Northington, who was a member of the group known as "the king's friends," was instrumental in procuring the dismissal of the marquess of Rockingham and the recall of Pitt to office in 1766, and he himself joined the government as lord president of the council, Lord Camden becoming chancellor. He resigned office in 1767, and died at his residence in Hampshire on Jan. 14, 1772.

See Lord Henley, *Memoir of Robert Henley, Earl of Northington* (1831); Campbell's *Lives of the Chancellors*; Foss's *Judges of England*; Horace Walpole's *Memoirs*.

NORTH LITTLE ROCK, a city of Pulaski county, Arkansas, U.S.A., on the Arkansas river, opposite Little Rock; served by the Missouri Pacific, the Rock Island and the St. Louis Southwestern railways. Pop. 14,048 in 1920, 35% negroes. It is practically an industrial district of Little Rock, with extensive railroad shops, hardwood lumber mills and other manufacturing industries. The factory output in 1925 was valued at \$8,609,157.

NORTH PACIFIC COAST INDIANS. The Indians of the coast of southern Alaska, British Columbia, Washington, Oregon and northern California form a unit which has been recognized as distinct from other natives of North America. The principal tribes and stocks comprised are the Tlingit, Haida, Tsimshian, Kwakiutl, Nutka, Bella Coola and other Coast Salish, Chimakun, Makah, Chinook, Yakonan, Kus, Takelma, Yurok, Wiyot, Karok and the Hupa and other Athabascan groups. There is linguistic diversity, but the area lacks the usual Mexican features: agriculture, pottery, metallurgy, axes, shields, drums, sweat-houses, political organization, religious structures and altars,

group fetiches. Cultural stimulus has been derived from the backward tribes of north-east Asia, rather than from China and Japan. The culture is vigorously local and therefore complex. It is characterized by the following generic traits: dependence primarily on fish, especially salmon; coastal maritime navigation; development of wood working, including the carver's art; wealth accumulation, with an elaborate system of economic exchange and property law; the organization of society on the basis of hereditary rank dependent on economic status; religious cults heavily influenced by proprietary rights. Particular traits exemplifying these trends are: deep-sea fishing; whale hunting; large dug-out canoes with plank lashings for higher freeboard; mat sails; clothing largely of mats, with basketry hats; twined basketry with overlay decoration; villages of large, all-frame houses facing the beach or a river; totem poles and wooden grave monuments; boxes for cooking, storage, etc.; clubs, spoons, and most utensils, also rattles, masks, etc., elaborately carved or painted in a peculiar totemic-symbolic art style; dentalium shells, plates of native copper, boxes, etc., serving as standardized media of exchange, often with high fictitious credit values; potlatches or competitive socio-religious festivals with wealth distribution for prestige; loans with high rate of interest; division of society into rich nobles with titles, crests and privileges, commoners and slaves; marriage by purchase; secret religious societies with elaborate ranks and masks. The secret societies extend south to Juan de Fuca, the potlatch to Columbia river; the basic elements of the culture—canoes, frame houses, dentalia, wealth display and ranking, slavery—persist as far as northern California.

See P. E. Goddard, "Indians of the Northwest" (*Amer. Mus. Nat. Hist.*, 1924); also *Monographs* by F. Boas, G. M. Dawson, M. Eells, G. T. Emmons, G. Gibbs, P. E. Goddard, E. Gunther, C. Hill-Tout, G. Hunt, A. Krause, A. L. Kroeber, A. B. Lewis, T. F. McIlwraith, C. F. Newcombe, A. P. Niblack, E. Sapir, G. M. Sproat, J. G. Swan, J. R. Swanton, G. Vancouver and T. T. Waterman. (A. L. K.)

NORTH PLATTE, a city of Nebraska, U.S.A., 280 m. W. of Omaha. It is on the Lincoln highway, the main transcontinental airway, and the main line of the Union Pacific railroad. The population was 10,466 in 1920, 85% native white, and was estimated at 13,300 in 1928. The city has one of the largest icing plants in the country. The irrigated region raises sugar beet and hay. There is a station of the U.S. Weather Bureau and a State agricultural experiment station 4 m. S. "Scouts Rest," the ranch of Colonel W. F. Cody ("Buffalo Bill") is 3 m. N.W. North Platte was incorporated in 1871.

NORTH SEA, a sea bounded east by the continent of Europe and west by Great Britain. Its area was given by Murray (1888) as 162,600 sq.m., and by Kossinna (1921) as 575,000 sq.km., or 222,000 sq. statute miles. Murray estimated the volume of the North sea at 11,200 cu.m., and Kossinna at 54,000 cu.km., or 12,960 cu.m., giving mean depths of: 61 fathoms (112 metres) and 51.4 fathoms (94 metres) respectively. The North sea is thus shallow; its bed is part of the continental shelf on which the British Isles stand, and it slopes upwards with fair regularity, from north to south. In the south and east there is a broad coastal strip, over which the depth nowhere exceeds 40 metres. In about its middle latitude the Dogger Bank crosses the North sea from east to west, extending for about one-third of the whole distance; near the English coast the depth here is under 20 metres and it increases eastwards to about 40 metres. In one part of the Dogger, where the depth is not more than 13 metres, surf is observed in stormy weather as well as dirty water owing to the bottom deposits being stirred up. South of the Dogger there are local depressions, mostly of small area, in which the depth is as much as 45 fathoms, as in the "Silver pit." A bottom configuration strange to the bed of the North sea is known as "Norwegian channel." This is a gully broad and more than 250 metres deep, closely following the Scandinavian coast, and extending into the Skagerrack, in which the depth increases to as much as 660 metres.

History.—According to Jukes-Browne, the North sea, in its present form, first took shape as a result of the tectonic movements indicated by the break between the older and newer Pliocene deposits. The southern end of the North sea was probably little affected by the general subsidence which occurred during the

Glacial period; its boundary in this direction was apparently within the present land area of France and Belgium, while a narrow inlet may have run westwards between France and England in the present position of the Strait of Dover. Meanwhile immense quantities of ice detritus from Scotland and Scandinavia were deposited in the North sea, to a thickness of perhaps 200 metres, and the whole region was subsequently raised above sea-level, constituting the "structural surface" upon which the present river system was developed as a series of tributaries to a great river which formed a continuation of the Rhine. Finally the land subsided again, the plain of the North sea was again submerged.

Coasts.—The coasts of the southern part of the North sea are of no great height. In England they consist of low cliffs with sandy beaches, while on the continental side are immense flats and marshes, with parts below sea-level protected by sand-dunes and artificial dykes. It is not certain whether the rapid changes of coast-line now taking place in many parts are wholly due to the action of the sea or whether a secular sinking of the shores produces this effect. The erosion of the North sea coasts has been made a subject of minute study (in England especially by the British Association and a committee of the Royal Geographical Society), and Harmer has obtained interesting results by comparing the British and continental coasts as characteristic "weather" and "lee" shores.

Temperature and Salinity.—The physical conditions of the waters of the North sea have been extensively studied—since 1902 by expeditions sent out by the Swedish, Norwegian, Danish, German and British governments—under the supervision of the International Council for the study of the Sea (Copenhagen). The waters found in the North sea are classified as follows: (1) oceanic water of 35 *pro mille* salinity or more; (2) water of salinity 34 to 35 *pro mille*, called "North sea" water; (3) water of salinity 32 to 34 *pro mille*, found along the coasts of Holland, Germany, Denmark and Norway, and called "bank-water"; (4) water of 32 *pro mille* salinity or less, belonging to the stream flowing out from the Baltic. The Atlantic water enters the North sea by the passage between the Orkney and Shetland islands, in which way the whole volume of water in the North sea could be recruited in two years. Oceanic or Atlantic water also enters through the Strait of Dover; this inflow is, however, much smaller, and it would take some 20 years to fill the North sea.

Tides.—The tides of the North sea are of great complexity; their nature has been widely investigated during the last 20 years. On the north-east coast of Great Britain the tide runs southward, so that the co-tidal lines, or the lines of equal time of high water, go from north to south; e.g., high water is at 12 o'clock in the Moray firth, it is high water in the Humber five hours, and at Lowestoft nine hours, later. A second tide comes through the Strait of Dover into the southern part of the North sea, and moves to the right side, i.e., the Dutch-German coast, towards the north and the east. A third weak tide flows south-east towards the Norwegian coast. The three systems—the Scottish, the Channel and the Norwegian—meet to the east of the Dogger, so that there the co-tidal lines radiate from this centre. The range of the tides on the Scottish coast is mostly 4 metres and over, on the Dutch-German coast from 2 to 3 metres, and on the Norwegian coast less than 1 metre. (See also maps in the article TIDES.)

Fisheries.—The North sea is particularly rich in organisms of all kinds, and the abundance of food attracts fish in such quantities that the North sea fisheries are some of the most productive in the world. Flat fishes, and those feeding at the bottom on smooth ground, are chiefly caught by means of the trawl. The favourite trawling-grounds are the Dogger Bank in winter, and the shallow waters off the Continental coasts in summer. In rough ground, where the trawl cannot be used, hook-and-line fishing is carried on most successfully, and "mid-water" fish are also taken in this way, although the trawl and line fishing overlap considerably. Herring and mackerel are caught by means of drift-nets; herring are also caught by trawling, and in greater quantities than by drifting. The herring fishing off the British coasts exhibits a remarkable variation during summer and autumn, beginning in Shetland in June, and becoming progressively later southwards,

536 NORTH SEA FISHERIES CONVENTION—NORTHUMBERLAND

until it ends off the Norfolk coast in November.

The approximate landings of the North sea fisheries amounted in 1924 to 1,069,000,000 kg., consisting of herrings 683,500,000 kg., or 64% of the total catch. Then came haddock 10%, cod 6%, plaice 4%, whiting 3%, mackerel 1%, turbot, sole, halibut, etc. As regards the value of the catch, the North sea herring also came first, but only with 37% of the total value. One of the chief objects of the International Council for the Study of the Sea is to discover the true connection between the varying results of the high seas fishing in the North sea and the changing physio-chemical nature and movements of the waters of the North sea.

NORTH SEA FISHERIES CONVENTION: see FISHERIES, LAW OF.

NORTH SHIELDS, seaport, Northumberland, England, within the municipal and parliamentary borough of Tynemouth (*q.v.*, for history, etc.). The town of that name adjoins it on the east. It lies immediately above the mouth of the Tyne, opposite to South Shields, $7\frac{1}{2}$ m. E. of Newcastle by a branch of the L.N.E. railway. It is a town of modern growth, and in the harbour, there is, between piers, a depth of 29 ft. at spring-tides besides the quays. Coal and coke are largely exported, and corn, timber and esparto grass are imported. There is an extensive fish quay. There are marine engineering (engines, chain-cables, anchors), salt, rope, earthenware and stained glass works and some shipbuilding is carried on.

NORTH TONAWANDA, a city and a port of entry of Niagara county, New York, U.S.A., on the Niagara river, at the western terminus of the State Barge canal (opposite Tonawanda) 14 m. N. of Buffalo. It is on the boulevards connecting Buffalo and Niagara Falls, and is served by the Erie, the Lehigh Valley, the New York Central, the West Shore, electric railways and motor-bus lines. Pop. (1920) 15,482 (26% foreign-born white); 1928 local estimate 18,500. Though separately incorporated, the two Tonawandas are practically one community. They have a fine harbour, with 7 m. of docks and traffic in 1925 amounting to 504,752 tons by lake and 249,139 tons by canal. Electric power from Niagara falls is used. The cities have a large trade in white pine lumber, and manufacture stained shingles, paper, iron, petroleum products, musical instruments, radiators and various other commodities. The output of the factories within the limits of North Tonawanda was valued at \$27,620,581 in 1925. North Tonawanda was settled in 1809, incorporated as a village in 1865 and chartered as a city in 1897.

NORTHUMBERLAND, EARLS AND DUKES OF. The earldom, and later the dukedom, of Northumberland, are famous in English history by their connection with the house of Percy (*q.v.*).

In the year 1377 Henry de Percy, 4th Baron Percy, officiated as marshal of England at the coronation of Richard II. and was created earl of Northumberland. With his son Sir Henry Percy, the celebrated "Hotspur," the earl played a leading part in the history of the period, especially in bringing about the deposition of Richard II. and the accession of Henry IV. The quarrel of Northumberland and his son with King Henry over the ransom of their Scottish prisoners taken at Homildon Hill on Sept. 14, 1402 has been immortalized by Shakespeare; and in consequence of their rebellion all the earl's honours were for-

feited in 1406. He was not himself present at the battle of Shrewsbury in July 1403, when Hotspur was killed, but he was slain, heading a fresh rebellion, at Bramham Moor on Feb. 19, 1408.

The 1st earl of Northumberland was succeeded by his grandson, Hotspur's son, HENRY (c. 1394-1455), who was restored to the earldom and the estates of the Percies in 1414 and was killed at the battle of St. Albans in May 1455. The title then descended in the male line till the death of the 6th earl in 1537. During the Wars of the Roses the Percies took the Lancastrian side, which led to the attainder of Henry the 3rd earl (1421-1461) during the time of the Yorkist triumph, his forfeited title being conferred in 1464 by Edward IV. on John Neville, Lord Montagu (see the separate article, p. 538), by a patent which was cancelled a few years later. The earldom, together with the barony of Poynings which his father had obtained by marriage, was restored in 1473 to Henry Percy, son of the 3rd earl, who attached himself to Edward IV., acquiesced in the accession of Richard III., and submitted to Henry VII., by whom he was received into favour. His grandson Henry, the 6th earl (c. 1502-1537), left no direct heir, and the latter's nephew, Thomas Percy, was debarred from the succession by an attainder passed on his father for his participation in the Pilgrimage of Grace. In 1549, however, Thomas was restored in blood, and in 1557 he became by a new creation earl of Northumberland, 7th of his line. Meantime, in 1551, John Dudley, earl of Warwick, was created duke of Northumberland (see the separate article, p. 537), his title being, however, forfeited by attainder in 1553.

The earldom restored to the house of Percy by the creation of 1557 continued without interruption in the male line till 1670. The 7th earl was beheaded in 1572 for sharing in a conspiracy in which he was joined by the earl of Westmorland with the object of securing the release of Mary Queen of Scots and the free exercise of the Catholic religion. By the earl's attainder the baronies of Percy and of Poynings and the earldom of Northumberland of the older creation were forfeited, but owing to a clause in the patent the newer earldom of Northumberland and the other honours conferred in 1557 passed to his brother Henry (c. 1532-1585), who is usually known as the 8th and not the 2nd earl.

Henry's grandson, ALGERNON PERCY, 10th earl of Northumberland (1602-1668), son of Henry the 9th earl (1564-1632), became a peer in his father's lifetime as Baron Percy in 1626. Northumberland played a distinguished part in the Civil War. He was a friend of Strafford, and gave evidence at his trial which, though favourable on the important point of bringing the Irish army to England, was on the whole damaging; and he afterwards leaned more and more towards the popular party, of which he soon became leader in the House of Lords. He was a member of the committee of safety, and later of the committee of both kingdoms; and he took an active part in the attempts to come to terms with the king, whom he visited at Oxford for that purpose in 1643 and at Uxbridge two years later. Northumberland helped to organize the new model army; and in 1646 he was entrusted by parliament with the charge of the king's younger children. He led the opposition in the House of Lords to the proposal to bring Charles I. to trial, and during the Commonwealth he took no part in public affairs. At the Restoration he was called to the privy council by Charles II., and with his habitual moderation deprecated harsh proceedings against the regicides. His second wife, Elizabeth (d. 1705) daughter of Theophilus Howard, 2nd earl of Suffolk, brought him Northumberland House in the Strand, London, which was demolished in 1874 to make room for Northumberland avenue. On the death of his son Joceline, the 11th earl, in 1670, the male line became extinct.

George Fitzroy (1665-1716), third son of Barbara, duchess of Cleveland, the wife of Roger Palmer, earl of Castlemaine, by King Charles II., was created by his father earl of Northumberland in 1674, and duke in 1683. This second dukedom of Northumberland became extinct on his death at Epsom on July 3, 1716.

Meanwhile Elizabeth Percy, daughter of Joceline, the 11th earl, had married Charles Seymour, 6th duke of Somerset; and her son Algernon, the 7th duke, was in 1749 created Baron Warkworth and earl of Northumberland, with remainder to

his son-in-law, Sir Hugh Smithson, Bart., son of Langdale Smithson of Langdale, Yorkshire. Sir Hugh Smithson (c. 1714–1786) took the name and arms of Percy on inheriting the earldom in 1750; in 1766 he was created Earl Percy and duke of Northumberland; and in 1784 he was further created Baron Lovaine of Alnwick, with special remainder to his second son, Lord Algernon Percy. He took a prominent part in politics as a follower of Lord Bute, and was one of George III.'s confidential advisers, holding the office of lord-lieutenant of Ireland from 1763 to 1765, and that of master of the horse from 1778 to 1780. He was a man of cultivated tastes, and spent much money in repairing and improving Alnwick castle and his other residences. His wife, Elizabeth (1716–1776), inherited in her own right her father's barony of Percy. The duke was succeeded by his eldest son Hugh; and his second son Algernon, Lord Lovaine, was created earl of Beverley in 1790.

Hugh, 2nd duke of this line (1742–1817), first inherited his mother's barony of Percy. He was present at the battle of Minden, and although in parliament, where he was member for Westminster from 1763 to 1776, he had opposed the policy that led to the American war, he proceeded to Boston in 1774 as colonel commanding the 5th Fusiliers, a regiment that has since then been known as the Northumberland Fusiliers. He succeeded to the dukedom in 1786, and became general in 1793. His son Hugh, 3rd duke (1785–1847), was lord-lieutenant of Ireland in 1829–1830, when the Catholic Emancipation Act was passed, and was pronounced by Sir Robert Peel "the best chief governor that ever presided over the affairs of Ireland." Both he and his brother Algernon, 4th duke (1792–1865), who was created Baron Prudhoe in 1816, died without issue; the barony of Percy devolved on their great-nephew, the duke of Atholl, and the dukedom passed to George (1778–1867), eldest son of Algernon, 1st earl of Beverley, and so to his son, the 6th duke (1810–1899), and grandson, the 7th duke (b. 1846).

See Edward Barrington de Fonblanque, *The House of Percy* (2 vols., 1887); G. E. Cokayne, *Complete Peerage*, vol. vi. (1895).

NORTHUMBERLAND, ALAN IAN PERCY, 8TH DUKE OF (1880–), was born on April 17, 1880, a son of the 7th duke. He succeeded to the title in 1918. As one of the largest coal-owners in the north of England, he was summoned to appear as a witness before the Sankey Coal Commission (1919) and came much into public notice owing to his prolonged controversy with Robert Smillie, the leader of the miners, and subsequently to his anti-Communist campaign. In 1924 the duke acquired an interest in *The Morning Post* newspaper, sold by Lady Bathurst.

NORTHUMBERLAND, JOHN DUDLEY, VISCOUNT LISLE, EARL OF WARWICK, and DUKE OF (c. 1502–1553), was the eldest son of Henry VII.'s minister, Edmund Dudley (q.v.), by his second wife Elizabeth, daughter of Edward Grey, Viscount Lisle, and co-heiress of her brother John, Viscount Lisle. He was probably descended from the old baronial house of Sutton *alias* Dudley; but his father's attainder and execution in 1509 clouded his prospects. His mother, however, married as her second husband in 1511 Arthur Plantagenet, the illegitimate son of Edward IV., who in 1523 was created Viscount Lisle in his wife's right; and Lisle's rise in Henry VIII.'s favour brought young Dudley into prominence. In 1512 he was restored in blood, and in 1538 he was made deputy to his step-father, who was governor of Calais, and he does not appear to have suffered by Lisle's temporary disgrace and imprisonment in the Tower. Lisle died early in 1542, and Dudley was created Viscount Lisle on March 12 and was made warden of the Scottish marches in November, and lord high admiral of England in 1543 in succession to his future rival, Edward Seymour, earl of Hertford. He was also created a knight of the garter and sworn of the privy council. In 1544 he accompanied Hertford to the capture and burning of Edinburgh. On the capture of Boulogne in September Lisle was given command of the town and of the Boulonnais; in 1545 he directed the operations of the fleet in the Solent which foiled the French attack on Portsmouth and the Isle of Wight; and he was sent to Paris to ratify the peace concluded in 1546.

Lisle had thrown in his lot with the reforming party, and he took an active share in the struggle at Henry VIII.'s court for control of affairs when Henry should die. Hertford and he were described by the Spanish ambassador as holding the highest places in Henry VIII.'s affections and as being the only noblemen of fit age and ability to carry on the government. The Howards were infuriated by the prospect, and Surrey's hasty temper ruined their prospects. Lisle quarrelled bitterly with Bishop Gardiner, served as commissioner at Surrey's trial, and was nominated one of the body of executors to Henry's will from which Norfolk and Gardiner were excluded. On Henry's death Lisle was raised to the earldom of Warwick and promoted to be lord great chamberlain of England, again in succession to Hertford, who became duke of Somerset and Protector. He accompanied Somerset on his Pinkie campaign, and materially contributed to the winning of that victory. Nor did he exhibit any sympathy with the intrigues of the Protector's brother, Thomas Seymour, the lord high admiral; his subtler policy was to exasperate the brothers and thus weaken the influence of the house of Seymour. He helped to bring the admiral to the block in March 1549; and then used the Protector's social policy to bring about his deposition. Warwick detested Somerset's ideas of liberty and his championship of the peasantry against the inclosure movement; one of his own parks was ploughed up as a result of a commission of enquiry which Somerset appointed; and when the peasants rebelled under Kett, Warwick gladly took the command against them. His victory at Dussindale made him the hero of the landed gentry, and as soon as he had returned to London in Sept. 1549, he organized the general discontent with the Protector's policy into a conspiracy. He played upon the prejudices of Protestants and Catholics alike, holding out to one the prospect of more vigorous reform and to the other hopes of a Catholic restoration, and to all gentry the promise of revenge upon the peasants.

The coalition thus created effected Somerset's deposition and imprisonment in Oct. 1549; and the parliament which met in November carried measures of political coercion and social reaction. But the coalition split upon the religious question. Warwick threw over the Catholics and expelled them from office and from the privy council, and the hopes they entertained were rudely dashed to the ground. But it was difficult to combine coercion of the Catholics with the proscription of Somerset; the duke was therefore released early in 1550 and restored to the privy council; and his daughter was married to Warwick's son. Warwick himself assumed no position of superiority over his colleagues, and he was never made protector. But he gradually packed the council with his supporters, and excluded his enemies from office and from access to the king. His plan was to dominate Edward's mind, and then release him from the trammels of royal minority. He abandoned the Tudor designs on Scotland, and made a peace with France in 1550 by which it recovered Boulogne and was left free to pursue its advantage in Scotland. Nor did the betrothal of Edward to Henry's daughter Elizabeth prevent the French king from intriguing to undermine English influence in Ireland. In domestic affairs Warwick pushed on the Reformation with none of the moderation shown by Somerset; and the difference between the two policies is illustrated by the change effected between the first and second Books of Common Prayer. Warwick, however, was widely distrusted; and the more arbitrary his government grew, the more dangerous became Somerset's rivalry. A parliamentary movement had early been started for Somerset's restoration. Warwick therefore kept parliament from meeting, and the consequent lack of supplies drove him into the seizure of church plate, sale of chantry lands, and other violent financial expedients. At length he resolved to get rid of his opponent; his opposition was magnified into conspiracy, and in Oct. 1551, after Warwick had made himself duke of Northumberland and his ally Dorset, duke of Suffolk, and had scattered other rewards among his humbler followers, Somerset was arrested, condemned by the peers on a charge of felony, and executed (Jan. 22, 1552).

Parliament was permitted to meet on the following day, but for the next 18 months Northumberland grew more and more unpopular. He saw that his life was safe only so long as he con-

trolled the Government and prevented the administration of justice. But Edward VI. was slowly dying, and Northumberland's plot to alter the succession was his last desperate bid for life and power. Its folly was almost delirious. Edward had no legal authority to exclude Mary, and the nation was at least nine-tenths in her favour. Northumberland bullied the council and overawed London for a few days; but the rest of England was in an uproar, and as he rode out to take the field against Mary, not a soul cried "God speed." A few days later he returned as Mary's prisoner. He was tried for treason, professed himself a Catholic in the delusive hope of pardon, and was executed on Aug. 22. He was a competent soldier and one of the subtlest intriguers in English history; but he had no principles. The violence of his pretended Protestantism was largely responsible for the reaction of Mary's reign. His best-known son was Robert Dudley, earl of Leicester, Queen Elizabeth's favourite.

NORTHUMBERLAND, JOHN NEVILLE, EARL OF (c. 1430-1471), English soldier, was the third son of Richard Neville, earl of Salisbury, and a brother of Richard Neville, earl of Warwick, the "king-maker." In 1459-61 he was twice a prisoner of the Lancastrians and in 1463 as warden of the east marches towards Scotland, he was responsible for the Yorkist victories at Hedgeley Moor and at Hexham in April and May 1464. In this year (1464) he was created earl of Northumberland, the Percies being now crushed, and their head, Henry Percy, being in prison. Northumberland did not at first join his brother Warwick and the other Nevilles when they revolted against Edward IV., but neither did he help the king. Edward, doubtless suspecting him, restored the earldom of Northumberland and its vast estates to Henry Percy, while John Neville's only recompense was the barren title of marquess of Montagu. At Pontefract in 1470 he and his men declared for Henry VI., a proceeding which compelled Edward IV. to fly from England, and under the restored king he regained his position as warden, but not the earldom of Northumberland. He did not attempt to resist Edward IV. when this king landed in Yorkshire in March 1471, but he fought under Warwick at Barnet, where he was slain on April 14, 1471.

NORTHUMBERLAND, the northernmost county of England. The area, included in the North of England basin, is 2,018 square miles. The higher land, including the north Pennines and the Cheviots, lies in the west and north. The Cheviot hills, rising to 2,676 ft., are formed by the intrusion of an igneous dome in Tertiary times, and between them and the northern Pennines we have the lower line of the Tyne Gap, giving an important way for routes from west to east. The larger rivers generally flow eastward, the chief exception being the Till which flows northward, to join the Tweed, along a bed of shales less resistant than the remainder of the region.

The number of weapons of Neolithic age which have been found in the county show that it was occupied by man in those times. Most implements have been found along a broad band of country north-eastward from Hexham to Alnwick, that is, along the lower levels of the limestone lands. In later times, the evidence of beaker-pottery shows that Northumberland was probably invaded from across the North sea at the dawn of the Metal age. The evidence for the pre-Roman Iron age is not great and the Bronze age may have continued far longer than in the south of England. The county was occupied by the Romans some time after A.D. 80 and about 124. Hadrian built his wall from the Tyne to the Solway to defend his northern frontier, but the region as a whole was not thoroughly Romanized like the south-eastern parts of Britain. Hadrian's wall marked the frontier south of which the Romans never retreated until they finally left Britain, but they often advanced farther north which northern region was crossed by military roads. The wall ran across the county a few miles north of the Tyne from near Haltwhistle to Wallsend. On the wall there was the fort of Magnae, near Haltwhistle, where the road from Kirkby Thore along the south Tyne abutted on the

wall. There was a settlement at Corbridge where the main road from the south crossed the Tyne and a fort near Halton where the road met the wall. At the eastern end of the wall there was a fort and another at Newcastle guarding a route across the Tyne. Within the wall, from Halton to Magnae through the Tyne Gap, ran another road.

History.—The first English settlement in the kingdom of Bernicia, which included what is now Northumberland, was effected in 547 by Ida, who pushed through the narrow strip of territory between the Cheviots and the sea, and set up a fortress at Bamburgh, which became the royal seat of the Saxon kings. About the end of the 6th century Bernicia was first united with the rival kingdom of Deira under the rule of Aethelfrith, and the district between the Humber and the Forth became known as the kingdom of Northumbria. In 634 Cadwalla was defeated at Hefenfeld (the site of which lies in the modern parish of St. John Lee) by Oswald, under whom Christianity was definitely established in Northumbria, and the bishop's see fixed at Hexham, where Bishop Wilfrid erected the famous Saxon church. Oswald also erected a church of stone at Tynemouth, which was destroyed in 865 in an incursion of the Danes. The Danes later overran the region, but in Northumberland, the English princes continued to reign at Bamburgh as vassals of the Danes, and not a single place-name with the Danish suffix "by" or "thorpe" is found north of the Tyne. The English names are, however, often associated with those of Gaelic or Cymric origin. In 938 Aethelstan annexed Northumberland to his dominions, and the Danish authority was annulled until its re-establishment by Canute in 1013. The vigorous resistance of Northumbria to the Conqueror was punished by ruthless harrying. The Normans rebuilt the Saxon monasteries of Lindisfarne, Hexham and Tynemouth; Eustace Fitz John founded Alnwick abbey, and other Norman abbeys were Brinkburn, Hulne, the first Carmelite monastery in England, Blanchland and Newminster. Castles were set up at Alnwick, Warkworth, Prudhoe, Dunstanborough, Morpeth, Ford, Chillingham, Langley, Newcastle, Bamburgh, Wark and Norham, a stronghold of the palatine bishops of Durham.

The term Northumberland is first used in its contracted modern sense in 1065 in an entry in the Saxon Chronicle relating to the northern rebellion. The county is not mentioned in the Domesday Survey, but the account of the issues of the county is entered in the Great Roll of the Exchequer for 1131. In the reign of Edward I. the county of Northumberland comprised the whole district between the Tees and the Tweed, and included liberties belonging to the bishop of Durham, archbishop of York, the king of Scotland, the earl of Lancaster and the earl of Angus. These franchises were all held exempt from the ordinary jurisdiction of the shire. By statute of 1495-96 the lordship of Tynedale was annexed to Northumberland on account of flagrant abuses of the liberties of the franchise; that of Hexham in 1572; Northamshire, Islandshire and Bedlingtonshire continued to form detached portions of Durham until 1844, when they were incorporated with Northumberland. The division into wards existed at least as early as 1295, the Hundred Roll of that year giving the wards of Coquetdale, Bamburgh, Glendale and Tynedale.

The shire-court for Northumberland was held at different times at Newcastle, Alnwick and Morpeth, until by statute of 1549 it was ordered that the court should thenceforth be held in the town and castle of Alnwick. The assizes were held at Newcastle, and the itinerant justices, on their approach to the county, were met by the king of Scotland, the archbishop of York, the bishop of Durham and the prior of Tynemouth, who pleaded their liberties either at a well called Chille near Gateshead, if the justices were proceeding from York, or, if from Cumberland, at Fourstanes. In these franchises the king's writ did not run, and their owners performed the office of sheriff and coroner. The burgesses of Newcastle claimed return of writs in their borough and the town was made a county by itself by Henry IV. in 1400, and has jurisdiction in admiralty cases. The county was in the diocese of Durham. But in 1882 Northumberland was formed into a separate diocese with its see at Newcastle. Northumberland has been the scene of perpetual inroads by the Scots and the churches were

often so built as to form refuges against the invaders. Norham, Alnwick and Wark were captured by David of Scotland in the wars of Stephen's reign, and in 1290 it was at Norham castle that Edward I. decided the Scottish succession in favour of John Balliol.

In 1295 Robert de Ros and the earls of Athol and Menteith ravaged Redesdale, Coquetdale and Tynedale. In 1314 the county was ravaged by Robert Bruce, and in 1382 by special enactment the earl of Northumberland was ordered to remain on his estates in order to protect the county from the Scots. In 1388 Henry Percy was taken prisoner and 1,500 of his men slain at the battle of Otterburn. Alnwick, Bamburgh and Dunstanborough were garrisoned for the Lancastrian cause in 1462, but after the Yorkist victories of Hexham and Hedgley Moor in 1464, Alnwick and Dunstanborough surrendered, and Bamburgh was taken by storm. In 1513 the king of Scotland was slain in the battle of Flodden Field on Branxton moor. During the Civil War of the 17th century Newcastle was garrisoned for the king by the earl of Newcastle, but in 1644 it was captured by the Scots under the earl of Leven, and in 1646 Charles was led there a captive under the charge of David Leslie. The county of Northumberland was represented by two members in the parliament in 1290, and in 1295 Bamburgh, Corbridge and Newcastle-upon-Tyne each returned two members. Today, the parliamentary divisions of the county are Berwick-upon-Tweed, Hexham and Wansbeck, each returning one member; while the parliamentary borough of Newcastle-upon-Tyne returns four members, and Morpeth, Wallsend and Tynemouth one each.

Industries and Agriculture.—The early industrial development of Northumberland was much impeded by the constant ravages of internal and border warfare. Again Aeneas Sylvius Piccolomini (Pope Pius II.) who passed through the county disguised as a merchant in 1436, leaves a picture of its barbarous and desolate condition, and as late as the 17th century, Camden, the antiquary, describes the lands as rough and unfit for cultivation. The mineral resources, however, appear to have been exploited to some extent from remote times. It is certain that coal was used by the Romans in Northumberland. In a 13th-century grant to Newminster abbey a road for the conveyance of sea-coal from the shore about Blyth is mentioned, and the Blyth coal-field was worked throughout the 14th and 15th centuries. The coal trade on the Tyne did not exist to any extent before the 13th century, but from that period it developed rapidly, and Newcastle acquired the monopoly of the river shipping and coal trade. The building of ships to carry the coal laid the foundations of the great modern shipbuilding industries. Lead was exported from Newcastle in the 12th century, probably from Hexhamshire, the lead mines of which were very prosperous throughout the 16th and 17th centuries. In a charter from Richard I. to Bishop Pudsey creating him earl of Northumberland, mines of silver and iron are mentioned, and in 1240 the monks of Newminster had an iron forge at Stretton. A saltpan is mentioned at Warkworth in the 12th century; in the 13th century the salt industry flourished at the mouth of the river Blyth, and in the 15th century formed the principal occupation of North and South Shields.

In the reign of Elizabeth glasshouses were set up at Newcastle by foreign refugees, and the industry spread rapidly along the Tyne. Tanning, both of leather and of nets, was largely practised in the 13th century, and the salmon fisheries in the Tyne were famous in the reign of Henry I. The height of the land and the composition of the soil together prevent the county from being rich agriculturally. In 1926 the total acreage under crops and grass was 656,936 of which 166,316 ac. were arable land. As would be expected in a northern county, the chief grain crops are oats and barley while the crop next in acreage is turnips and swedes. Potatoes covered nearly 5,000 ac., and the acreage of clovers and rotation grasses for hay was 40,099. The number of cattle in the county is fairly large, but the large acreage of hill-land makes it pre-eminently a sheep country, these animals numbering over a million in 1926. Manufactories centre on the Tyne, which is a region of ironworks, blast-furnaces, shipbuilding yards, ropeworks, coke-ovens, chemical works and manufactories of glass, electrical apparatus, pottery and fire-bricks, from above Newcastle to the sea. Machines, appliances, conveyances and tools are the principal

articles of manufacture in metal.

Communications are provided almost wholly by the L.N.E. railway.

The area of the administrative county is 1,291,515 ac., with a population (1921) of 746,096. Population is densest in the south-east, where the mining district and the Tyneside industrial area are situated. The county is in the north-eastern circuit, and assizes are held at Newcastle-upon-Tyne.

NORTHUMBERLAND, a manufacturing borough of Northumberland county, Pennsylvania, U.S.A., immediately north of Sunbury, at the confluence of the east and west branches of the Susquehanna river. It is served by the Lackawanna, the Pennsylvania and the Reading railways. Pop. (1920) 4,061 (95% native white); estimated locally (1928) at 5,750. Northumberland was the home of Joseph Priestley, the English chemist, from 1794 until his death (1804), and his dwelling has been preserved as a memorial by the chemists of America.

NORTHUMBRIA, one of the most important of the Anglo-Saxon kingdoms, extended from the Humber to the Forth (*regnum Northanhymbrorum*). Originally it comprised two independent kingdoms, Bernicia and Deira (*q.v.*), each of which had a dynasty of its own. The first known king of the former was Ida, who, according to tradition, acquired the throne in 547 and reigned twelve years. To him the foundation of Bamburgh is attributed. Four of Ida's sons successively occupied his throne: Glappa 559-560, Adda 560-568, Aethelric 568-572 and Theodoric 572-579. Of the first three nothing is known, but Theodoric is said (*Historia Brittonum*) to have been besieged by the Welsh under Urien in Lindisfarne. Theodoric was succeeded by Frithuwald 579-585/6 and Husa 586-592/3. Then Aethelfrith (*q.v.*), son of Aethelric, came to the throne. He greatly extended his territories at the expense of the Welsh, and eventually provoked an invasion of Aidan, king of the Scots, whom he defeated at a place called Daegastan (603). The first king of Deira of whom we know was Ella, or Aelle, who, according to Bede, was still reigning when Augustine arrived in 597. Aethelfrith eventually acquired possession of Deira, expelling Aelle's son Edwin (*q.v.*). Thenceforward, with rare intervals, the two kingdoms remained united.

Aethelfrith became involved in war with the Welsh towards the end of his reign and captured Chester, probably about 613. Shortly afterwards, in 616, he was slain in battle on the river Idle by Edwin, who was assisted by the East Anglian king Raedwald. Edwin now became king over both Northumbrian provinces. By his time the kingdom must have reached the west coast, as he is said to have conquered the islands of Anglesea and Man. Under Edwin the Northumbrian kingdom became the chief power in the country. At his death in 633 the kingdom was again divided, Deira falling to his nephew Osric, while Bernicia was occupied by Eanfrith son of Aethelfrith. Both these kings were slain by Cadwallon in the following year, but shortly afterwards the Welsh king was overthrown by Oswald (*q.v.*), brother of Eanfrith, who reunited the whole of Northumbria under his sway and acquired a supremacy analogous to that previously held by Edwin. After Oswald's defeat and death at the hands of Penda in 642 Bernicia fell to his brother Oswio, while Oswine son of Osric became king in Deira, though probably subject to Oswio. Oswine's death was compassed by Oswio in 651, and the throne of Deira was then obtained by Aethelwald son of Oswald. He is not mentioned, however, after

655, so it is probable that Deira was incorporated in the Bernician kingdom not long afterwards. After Oswio's victory over Penda in 654-655 he acquired a supremacy over the rest of England similar to that held by his predecessors. The Mercians, however, recovered their independence in 658, and from this time onward Northumbria played little part in the history of southern England. But Oswio and his son Ecgrifh greatly extended their territories towards the north and north-west, making themselves masters of the kingdoms of Strathclyde and Dalriada, as well as of a large part of the Pictish kingdom. Ecgrifh (*q.v.*), who succeeded on Oswio's death in 671, expelled the Mercians from Lindsey early in his reign, but was in turn defeated by them in 679, his brother Aelfwine being slain. From this time onwards the Humber formed the boundary between the two kingdoms. In 684 we hear of the first English invasion of Ireland, but in the following year Ecgrifh was slain, and his army totally destroyed by the Picts at a place called Nechtansmere (probably Dunnichen Moss in Forfarshire). The Picts and Britons now recovered their independence; for Aldfrith, apparently an illegitimate son of Oswio, who succeeded, made no attempt to reconquer them. He was a learned man, and during his reign the Northumbrian kingdom partially recovered its prosperity. He was succeeded in 705 by his son Osred, and under him and his successors Northumbria began rapidly to decline through the vices of its kings. Osred was slain in 716. He was succeeded by Coenred 716-718, and Coenred by Osric 718-729. The next king was Ceolwulf, to whom Bede dedicated his *Historia Ecclesiastica* in 731. In the same year he was deposed and forced to become a monk, but was soon restored to the throne. In 737 he voluntarily retired to a monastery and left the kingdom to his cousin Eadberht. The latter appears to have been a vigorous ruler; in the year 740 we hear of his being involved in war with the Picts. Aethelbald of Mercia seems to have taken advantage of this campaign to ravage Northumbria. In 750 Eadberht is said to have annexed a large part of Ayrshire to his kingdom. Finally in 756, having now allied himself with Oengus king of the Picts, he successfully attacked Dumbarton (Alcluith), the chief town of the Britons of Strathclyde. Eadberht showed considerable independence in his dealings with the church, and his brother Ecgrifh was from 734 to 766 archbishop of York. In 758 Eadberht resigned the kingdom to his son Oswulf, and became a monk.

Oswulf was slain by his household at a place called Mechil Wongtun in 759. Moll Aethelwald, who may have been a brother of Eadberht, succeeded, and after a victory over a certain Oswine, who fell in the battle, abdicated and became a monk probably under compulsion in 765. His successor Alchred sent an embassy to Charlemagne in 768 and was deposed in 774, whereupon he fled to Bamburgh and afterwards to the Picts. His deposition has been ascribed to a formal act of the Witan, but this seems an antedating of constitutional methods and the circumstances point to a palace revolution. The successor of Alchred was Aethelred son of Moll Aethelwald. In 778 three high-reeves were slain at the instigation of the king. Aethelred was expelled during the next year, perhaps in consequence of this event, and Aelfwald son of Oswulf became king. Aelfwald was murdered by Sigca in 789, whereupon Osred his nephew the son of Alchred succeeded. In 790 the banished Aethelred returned to the throne and drove out Osred, whom he put to death in 792. Aethelred, who had married Aelflaed the daughter of Offa, also killed Aelf and Aelfwine, the sons of Aelfwald and was murdered himself at Corbridge in 796. Oswald, who is called *patricius* by Simeon of Durham, succeeded, but reigned only twenty-seven days, when he was expelled and eventually became a monk. Eardwulf *dux*, who had apparently fled abroad to escape the wrath of Aethelred, was now recalled and held the crown until 807 or 808. Aelfwald then became king but Eardwulf was restored in 808 or 809 after appealing to the emperor and the pope. Eanred, son of Eardwulf, probably came to the throne in 809 and reigned until 841. It was during his reign in 827 that Northumbria acknowledged the supremacy of Ecgrifh, king of Wessex. Eanred was succeeded by his son Aethelred, who was slain in 850, when Osberht came to the throne and reigned until 863. On the expulsion of Osberht, Ella or Aelle,

succeeded. The chroniclers emphasize the fact that this king was not of royal descent. He is said to have slain Ragnarr Loðbrok. In the year 866 Loðbrok's sons Ingwaere (Ivarr, *q.v.*), Healfdene, Ubba and others brought a vast army to England to avenge the death of their father. In the following year they obtained possession of York. Ella seems now to have made peace with the exiled king Osberht, and their united forces succeeded in recovering the city. In the great battle which ensued the Northumbrian army was annihilated and both kings were slain (the death of Ella, according to Irish tradition, being due to the treachery of one of his followers). The southern part of Northumbria now passed entirely into the hands of the invaders, but they allowed a certain Ecgrifh to reign over the portion of the kingdom north of the Tyne. Ecgrifh was expelled in 872 and died in the course of the following year. His successor Ricsig died in 876 and was followed by Ecgrifh II., who reigned until 878. He was the last English king who reigned in Northumbria. After him the chief power north of the Tyne came into the hands of a certain Eadulf of Bamburgh, who did not take the kingly title, but accepted the overlordship of Alfred the Great perhaps in 886. In the winter of 874-75 Healfdene returned to Northumbria, which he partitioned next year among his followers. After an interregnum of a few years a certain Guthred became king in 883. He is said to have been a slave and to have been appointed king at the command of St. Cuthbert who appeared to Eadred the abbot of Carlisle in a dream. There is some reason for the conjecture that he belonged to the family of Loðbrok. He died in 894, after which date little is known of Northumbrian history for some years.

About 919 the country was invaded by vikings from Ireland under Ragnall, grandson of Ivarr, who seized York and occupied the lands of St. Cuthbert. Aldred, the son of Eadulf, who now ruled north of the Tyne, appealed to Constantine II., king of the Scots, for help, but the Scottish and Northumbrian armies were defeated at Corbridge. Shortly after this, however, all the northern princes submitted to Edward the Elder. Ragnall was succeeded by Sihtric, who married Aethelstan's sister. He died in 926, and his brother and successor Guthfrith was soon afterwards expelled by Aethelstan and fled to Eugenius, king of Strathclyde. The Welsh and Scottish kings, however, both submitted to Aethelstan, and Guthfrith was again driven into exile. He died in 934, leaving a son Anlaf (Olaf) Godfredsson or Godfreyson. In 934 Aethelstan invaded Scotland as far as the Tay. In 937 a great fleet and army were brought together by Constantine and Anlaf Godfreyson from Ireland. Aethelstan, however, won a complete victory over them at a place called Brunanburh. Anlaf Godfreyson escaped to Ireland but returned to England after Aethelstan's death, occupied York and compelled Edmund to cede to him all Danish Mercia north of Watling street. He died in 941, and a series of obscure Scandinavian kings of York followed him until 954 when Northumbria was conquered by Edred king of Wessex. Eadred placed Northumbria in the hands of a certain Osulf, who is called high-reeve at Bamburgh. In the reign of Edgar, Oslac was appointed earl of southern Northumbria, but he was banished at the beginning of the following reign. The next earl was Waltheof and after him Uhtred, who defeated Malcolm II., king of the Scots, in 1006. Twelve years later, however, the Northumbrians were completely defeated at Carham, and Lothian was annexed by the Scots (*see* Lothian). Uhtred was slain by the orders of Canute, who gave the province to Eric (Eirikr) earl of Lade. Shortly afterwards, however, part of it at least came into the hands first of Eadulf and then of Aldred and another Eadulf, the brother and sons respectively of Uhtred. The younger Eadulf was slain by Siward, probably in the reign of Harlactuut. Siward held the earldom till his death in 1055, when it was given to Tostig, son of earl Godwine, and after his banishment to Morkere, son of Aelfgar, earl of Mercia. Tostig's banishment led to the invasion of Harold Hardrada, king of Norway, and the battle of Stamford Bridge, in which both perished.

NORTH-WEST FRONTIER PROVINCE, the most northerly province of British India, created on Oct. 25, 1901. Roughly it may be defined as the tract of country north of Baluchistan, lying between the Indus and Afghanistan. More exactly it consists of (1) the cis-Indus district of Hazara; (2) the comparatively narrow strip between the Indus and the hills constituting the settled districts of Peshawar, Kohat, Bannu and Dera Ismail Khan; and (3) the rugged mountainous region between these districts and the borders of Afghanistan, which is inhabited by independent tribes. This last region is divided into five agencies: Dir, Swat and Chitral, with headquarters at Malakand; Khyber, Kurram, Tochi and Wana. The province lies between $31^{\circ} 4'$ and $36^{\circ} 57' N.$, and $69^{\circ} 16'$ and $74^{\circ} 7' E.$ The approximate area is 38,665 sq.m., of which 13,419 sq.m. are British territory and the remainder is held by tribes under the political control of the agent to the governor-general.

Rivers and Mountains.—The mountains of the Hindu Kush running from east to west form the northern boundary of the province, and are met at the north-east corner of the Chitral agency by the continuation of an outer chain of the Himalayas after it crosses the Indus above the Kagan valley. From this chain minor ranges run in a south-westerly direction the whole length of Bajour and Swat, till they merge into the Mohmand hills and connect the mid-Himalayas with the Safed Koh. The Suliman system lies south of the Gomal unconnected with the northern hills. To the east the Safed Koh extends its spurs into the Kohat district. The Salt Range crosses the Indus in the Mianwali *tahsil* of the Punjab, and forms the boundary between Bannu and Dera Ismail Khan, merging eventually in the Waziri hills. The chief peaks in the province are Kaisargarh (11,300 ft.) and Pir Ghol (11,580 ft.) in Waziristan; Shekh Budin (4,516 ft.), in the small range; Sikaram (15,621 ft.) in the Safed Koh; Istragh (18,900 ft.), Kachin (22,641 ft.) and Tirach Mir (25,426 ft.), in the Hindu Kush on the northern border of the Chitral agency; while the Kagan peaks run from 10,000 ft. to 16,700 ft.

With the exception of the Kunhar river, which flows down the Kagan valley to the Jhelum, the whole drainage of the province finds its way into the Indus. (See INDUS: KABUL RIVER.)

The Pathan Races.—The North-West Frontier Province as now constituted may be described as the country of the Pathans (*q.v.*). The true Pathan is possibly of Indian extraction. But around this nucleus have collected many tribes of foreign origin. The whole have now become blended by the adoption of a common language, but remain tribally distinct; all alike have accepted Islam, and have invented traditions of common descent which express their present association. For centuries these tribes maintained their independence in the rugged hills which flank the present kingdom of Afghanistan. In the 15th century they began to settle in the plains. The 16th century saw the Pathan tribes established in their present homes. The spirit of independence which always characterized them soon brought them into collision with the Mogul empire. In the 17th century, after a long struggle, the settlers in the plains wrested from Aurangzeb terms which left them almost as independent as their brothers in the hills. The invasion in 1738 of Nadir Shah, who traversed the province from Peshawar to Dera Ismail Khan, is a landmark in the history of the frontier. From his death to the rise of Ranjit Singh, the frontier districts remained an appendage of the Durani empire. Little control was exercised by the rulers of Kabul, and the country was administered by local chiefs or Afghan Sirdars very much as they pleased. The Sikh invasions began in 1818, and from that date to the annexation by the British government the Sikhs were steadily making themselves masters of the plain tracts. After the Second Sikh War, by the proclamation of March 29, 1849, the frontier districts were annexed by the British Government. From that time until the creation of the North-West Frontier Province the settled districts formed part of the Punjab, while the independent tribes were controlled at different times by the Punjab government, and the government of India. Their turbulence still continued, and since 1849 they have been the object of over fifty

punitive expeditions. The chief tribes, under the political control of the N.W. Frontier agency, besides Chitralis and Bajouris, are the Utman Khel, Yusufzais, Hassanzais, Mohmands, Afridis, Jowakis, Mullagoris, Orakzais, Zaimukhts, Chamkannis, Khattaks, Bangashes, Turis, Mahsuds, Wazirs, Bhitanis and Sheranis, etc.

Creation of the Province.—The North-West Frontier Province differs from the older provinces of India in having been artificially built up out of part of a previous province together with new districts for a definite administrative purpose. The proposal to make the frontier districts into a separate province, administered by an officer of special experience, dates back to the viceroyalty of Lord Lytton, who, in a famous minute of April 22, 1877, said:—

"I believe that our North-West Frontier presents at this moment a spectacle unique in the world; at least I know of no other spot where, after 25 years of peaceful occupation, a great civilized power has obtained so little influence over its semi-savage neighbours, and acquired so little knowledge of them, that the country within a day's ride of its most important garrison is an absolute *terra incognita*, and that there is absolutely no security for British life a mile or two beyond our border."

The result of this minute was that a frontier commissionership, including Sind, was sanctioned by the home Government, and Sir Frederick (afterwards Lord) Roberts had been designated as the first Commissioner when the outbreak of the Second Afghan War caused the project to be postponed. It was afterwards shelved by Lord Ripon. Twenty-three years elapsed before the idea was revived and successfully brought to completion by Lord Curzon, whose scheme was on a more modest scale than Lord Lytton's. It omitted Sind altogether, and confined the new province to the Pathan trans-Indus districts north of the Gomal. The present administration of the province is conducted by a chief commissioner and agent to the governor-general. It has been specially omitted from the scope of the "reforms" in India.

Population.—The census of 1901, omitting the great majority of the frontier tribes, gave a total population of 2,125,480. In 1921, the figure increased to 2,251,340. The province is mainly agricultural. The towns, except Peshawar and Dera Ismail Khan, are either expansions of large agricultural villages or bazaars which have grown up round the many cantonments of the province. The great majority of the population are Pathan by race and Mohammedan by religion. The predominant language is Pushtu (*q.v.*). The conquered strata of the population speak servile Indian dialects, called Hindki in the north and Jatki in the south, while Gujar is spoken by the large Gujar population in Hazara and north of Peshawar.

Crops, Climate, Etc.—The area under cultivation represents an average of 1.3 acres per head of the total, and of nearly 1.5 acres per head of the rural population. The limit of profitable cultivation has almost been reached. The Pathan, however, is a slovenly cultivator and slow to adopt new methods. The principal crops are—in the cold weather, maize and *bajra*; in the spring, wheat, barley and gram. Rice and sugar-cane are largely grown on the irrigated lands of Hazara, Peshawar and Bannu districts, and the well and canal irrigated tracts of Peshawar district produce fine crops of cotton and tobacco. In the trans-border agencies the valleys of the Swat, Kurram and Tochi yield much rice.

The climatic conditions of the province are extremely diversified. Dera Ismail Khan district is one of the hottest areas in the Indian continent, while over the mountain region to the north the weather is temperate in the summer and intensely cold in the winter. The air is generally dry, and hence the daily and annual range of temperature is frequently very large. There are two seasons of rainfall over the province; the monsoon season, when supplies of moisture are brought up by the ocean winds from the Arabian Sea and the Bay of Bengal; and the winter season, when storms advancing eastwards from Persia and the Caspian districts occasion winds, widespread rain and snowfall. Both sources are precarious and instances are not infrequent of the almost entire failure of either the winter or the summer rainfall.

Canals are the main source of irrigation in the province, and fall under three heads: (1) Private canals in the various districts, the property of the people and managed on their behalf; (2) the

Michni Dilazak and Shabkadar branch in Peshawar, constructed by the district board, which receives water rates; and (3) the Swat and Kabul river canals, which were constructed by and are the property of government, and are managed by the irrigation department. About 20% of the cultivated area is irrigated by canals, 2% by wells and 3% by perennial streams. In the year 1925-26 the irrigated area was 368,481 acres.

Railways.—The railways of the province are mostly intended in the first instance for strategic purposes. The main line of the North-Western railway from Rawalpindi to Peshawar after being first extended 9 m., to Jamrud at the entrance to the Khyber Pass, in Nov. 1925 received further extension of 27 m. through the Khyber to the Afghan frontier. From Nowshera a branch runs to Dargai at the foot of the Malakand Pass. From Rawalpindi again another branch crosses the Indus at Kushalgarh (*q.v.*) and runs to Kohat, whence a 2 ft. line runs to Thal at the foot of the Kurram valley.

Enriquez, *The Pathan Borderland, from Chitral to Dera Ismail Khan* (Calcutta, 1921). (T. H. H.; X.)

NORTH-WEST TERRITORIES, at first a general name given to all the districts of British North America lying north-west of the St. Lawrence basin. In the British North American Act of 1867, provision was made for the admission to Canada of "Rupert's Land and the North West Territory." Manitoba was formed out of this district in 1870, and the remaining area was called the "North-West Territories." In 1881 the limits of Manitoba were enlarged at the expense of the "North-West Territories." In 1905 Saskatchewan and Alberta were formed out of the remaining area. Further delimitation took place in 1912, and in 1928 the North-West Territories consisted of the Canadian mainland east of the Rockies, west of Hudson bay and north of latitude 60° N., together with all the northern archipelago. This area is divided into the provisional districts of Mackenzie, Keewatin and Franklin. The extent of these territories is estimated at 1,242,224 square miles. These northern regions are nearly uninhabited; parts are even unexplored. In 1921 the population amounted to 7,988. Of this number 3,873 were Indians, 3,242 Eskimos, 473 of British stock, 258 French and 142 others. The territories are administered by the North-west Territories' branch of the Department of the Interior. The government is carried on by a commissioner and five councillors.

Fur is an important product: for the season 1924-25, the number of pelts purchased by traders amounted to 148,885 valued at \$1,780,666. Agricultural possibilities are limited to the south of the Mackenzie district, where cereals and vegetables have been successfully grown in favourable years. The northern limit to timber growth runs diagonally from the mouth of the Mackenzie in the west to the mouth of the Churchill (in Manitoba) on Hudson bay. Precipitation is everywhere less than 14 in., the winters are long, dry and extremely cold. Heat waves occur in summer and actual maximum temperatures are quite high, yet keen night frosts in the early summer and very early autumn limit the growing season so as to make cereal growth and general agriculture very precarious. But in the short summers the so-called "barren lands" yield a profusion of wild flowers, heaths, mosses, lichens and in places, luxuriant grasses, and support vast herds of caribou. Pelts, hides and reindeer meat are of value.

NORTHWICH, a town in Cheshire, England, 171m. N.W. of London, on the L.M.S. and Cheshire lines railways. Pop. (1921), 18,381. It lies at the junction of the rivers Weaver and Dane. Of the 2,000,000 tons of salt annually produced in the British Isles, three quarters are yielded by this area. In its narrow and irregular streets many of the houses have sunk and are at fantastic angles, being strongly bolted to keep them secure, because of subsidences resulting from the pumping of brine. This latter method of salt production has largely replaced the mining of rock salt. The salt is conveyed to the Mersey ports for export, by the river Weaver, which is connected by a hydraulic lift with the Trent and Mersey canal on higher level.

NORTON, CAROLINE ELIZABETH SARAH (1808-1877), afterwards Lady Stirling-Maxwell, English writer, was born in London in 1808. One of the three beautiful granddaughters of Richard Brinsley Sheridan, daughters of his son Thomas, the "three Graces" of London society in the reign of George IV., she began to write before she was out of her teens. Her two sisters Helen and Georgina became respectively Lady Dufferin and duchess of Somerset. At the age of 17, Caroline published a merry satire, *The Dandies' Rout*, illustrated by herself; this was followed by *The Sorrows of Rosalie* (1829), and *The Undying One* (1830), a version of the legend of the Wandering Jew. She married in 1827 the Hon. George Norton, brother of Lord Grantley. The husband's persecutions culminated in 1836 in an action brought against Lord Melbourne for seduction of his wife, which the jury decided against Norton without leaving the box. The case against Lord Melbourne was so weak that it was suggested that Norton was urged to make the accusation by Melbourne's political enemies, in the hope that the scandal would prevent him from being premier when the princess Victoria should succeed William IV. In 1853 legal proceedings between Mrs. Norton and her husband were again entered on, because he not only failed to pay her allowance, but demanded the proceeds of her books. Mrs. Norton made her own experience a plea for addressing to the queen in 1855 an eloquent letter on the divorce laws, and her writings did much to ripen opinion for changes in the legal status of married women. George Meredith, in *Diana of the Crossways*, used her as the model for his "Diana." Mrs. Norton was not a mere writer of elegant trifles; her *Voice from the Factories* (1836) was a most eloquent and rousing condemnation of child labour. *The Dream, and other Poems* appeared in 1840. *Aunt Carry's Ballads* (1847), dedicated to her nephews and nieces, are written with charming tenderness and grace. Later in life she produced three novels, but perhaps her best work is her last, the half-humorous, half-heroic story of *The Rose of Jericho* in 1870. She died on June 15, 1877. Her husband died in 1875; and Mrs. Norton in the last year of her life married Sir W. Stirling-Maxwell.

See Jane G. Perkins, *The Life of Mrs. Norton* (1909).

NORTON, CHARLES ELIOT (1827-1908), American scholar and man of letters, was born at Cambridge, Mass., on Nov. 16, 1827. The descendant of a long line of clergymen and of Anne Bradstreet, the Puritans' "tenth muse," in his idealism, restraint and dignity he was a member of the New England group already passing into its decline. Yet in him there was, too, an alien strain that made him, after graduation from Harvard in 1846, take employment with an Oriental trading firm, for which as supercargo he travelled out to India. The leisurely trip through Europe on his return and his early contact with the culture of an older civilization made him feel sharply what he had been losing in life—"pleasure, opportunities, happiness, indeed, of a sort that nothing else can supply." He felt himself to be "half starved" in America, yet he knew that in the Old World he would be "half starved for this strange new one." Thenceforth his work was to be largely that of torchbearer and interpreter. As lecturer on and first professor of the history of art at Harvard (from 1874 to 1898 when he became emeritus), he was long considered the "oracle of the humanities." From his first publication of church hymns (1852), he turned to *Notes of Travel and Study in Italy* (1860), and to his later *Historical Studies of Church Building in the Middle Ages* (1880). A translator of *The New Life of Dante Alighieri* as early as 1859, he did what was probably his best literary work in his prose translation of the *Divine Comedy* (1891-92). He helped to develop the creative abilities of his own countrymen in his editorship (1864-68) with Lowell of the *North American Review*. For long years with unflinching grace and tact he edited the literary remains of many of his friends. *The Correspondence of Thomas Carlyle and Ralph Waldo Emerson* (1883), *Letters of John Ruskin to Charles Eliot Norton* (1904)—records of a rare friendship mutually profitable—the *Orations and Addresses of George William Curtis* (1894), *Henry Wadsworth Longfellow; a Sketch of his Life, together with Longfellow's Chief Biographical Poems* (1907), the *Letters of James Russell Lowell* (1894) all bear testimony to the variety of his

friendships in England and America and to his editorial discrimination. In allusion to this phase of his life, he suggested to Lowell as an inscription over his grave, "He had good friends, whom he loved." Yet his was never too exclusive a disposition. A lover of the beautiful in art, he was also a worker for the beautiful in life. Between 1846 and 1849 when he was still in the counting-house, he opened a night school for men and boys in Cambridge; he was a director of the movement for model lodging-houses in Boston; he was a zealous worker for the Union cause, especially through his editorial labours for the New England Loyal Publication Society. When he died (Oct. 21, 1908) at "Shady Hill," the gracious house in which he had been born, he left the memory of a serene and well-ordered life.

The best record of his life is afforded by his *Letters*, which were edited with biographical comment by his daughter Sara Norton and M. A. De Wolfe Howe (1913). Tributes to his work and personality may be found in *The Harvard Graduates' Magazine* (vol. 16, Dec. 1907; vol. 17, Dec. 1908) and in T. W. Higginson, *Carlyle's Laugh* (1909).

NORTON, THOMAS (1532-1584), English lawyer, politician and writer of verse, was born in London in 1532. He was educated at Cambridge, and early became a secretary to the protector Somerset. In 1555 he was admitted a student at the Inner Temple, and married Margery Cranmer, the daughter of the archbishop. From his eighteenth year Norton had begun to compose verse. He contributed sonnets to *Tottel's Miscellany*, and in 1560 he composed, in company with Sackville, the earliest English tragedy, *Gorboduc*, performed before Queen Elizabeth in the Inner Temple on Jan. 18, 1561. In 1562 Norton, who had served in an earlier parliament as the representative of Gatton, became M.P. for Berwick, and entered with great activity into politics, especially religious politics, and was employed on official business in the Channel islands and at Rome. Towards the end of his life he was a fanatical anti-Catholic. His punishment of the Catholics, as their official censor from 1581 onwards, led to his being nicknamed "Rackmaster-General." At last he was deprived of his office and thrown into the Tower. Walsingham presently released him, but he died on March 10, 1584.

For *Gorboduc* see DORSET, THOMAS SACKVILLE, 1ST EARL OF. The best account of Norton, and his place in literary history, is that of Sidney Lee in his *Dictionary of National Biography*. (E. G.)

NORWALK, a city of Fairfield county, Connecticut, U.S.A., 42 m. N.E. of New York city, on Long Island sound at the mouth of the Norwalk river. It is on Federal highway 1, and is served by the New York, New Haven and Hartford railroad and steamboats to New York. Pop. (1920) 27,743 (21% foreign-born white); 1928 local estimate over 32,000. The city's area of 25 sq.m. embraces districts of very diversified character: the port and manufacturing centres, summer resorts along the sound and residential sections old and new. Around the green (shaded by fine elms) are several old churches. The traffic of the harbour amounted to 159,232 tons in 1925, valued at \$6,612,634. Foreign commerce was represented by imports of 17,900 tons of ground wood. The city has important oyster fisheries. Its numerous and varied manufactures were valued in 1925 at \$36,345,528. The assessed valuation of property for 1926 was \$46,216,109. The site of Norwalk was purchased from the Indians in 1640 by Roger Ludlow and Daniel Patrick. The first settlement was made in 1649 by a small company from Hartford, and the town was incorporated in 1651. The city was formed by its consolidation in 1913 with the city of South Norwalk (chartered 1870). It was from Norwalk that Nathan Hale, disguised as a Dutch school teacher, started on his fatal errand to Long Island in Sept. 1776. The village was burned by the British under Governor Tryon on July 12, 1779, and a chair is preserved in which (the story goes) Tryon sat and watched the flames from Grumman's hill.

NORWALK, a city of northern Ohio, U.S.A., on Federal highway 20; the county seat of Huron county. It is served by the New York Central, the Wheeling and Lake Erie and electric railways. Pop. 7,379 in 1920, 92% native white; estimated locally at 8,300 in 1928. Century-old maple trees line most of the streets, and the manufacturing industries include canneries, wood-working plants and a large piano factory. Norwalk was settled in 1817

by colonists from Norwalk, Connecticut. It was incorporated as a town in 1829 and chartered as a city in 1881. It lay within the "Fire Lands" grant made in 1792 by the State of Connecticut to the people of eight Connecticut towns, to indemnify them for losses by fire during the British expeditions under Governor Tryon in 1779 and Benedict Arnold in 1781.

NORWAY (*Norge*), a kingdom of northern Europe, occupying the west and smaller part of the Scandinavian peninsula. Its east frontier marches with that of Sweden, except in the extreme north, where Norway abuts on Finland. On the north, north-west, west, the boundaries are the Arctic ocean, Norwegian sea (Atlantic ocean) and North sea respectively. The Skagerrak washes it on the south and south-east. The south extremity of the country is the island of Kraage near Mandal in 57° 57' N., and the north that of Cape Knivskjerodden (71° 11' N.), west of the North cape on the island of Magerö. Of the mainland, the promontory northernmost is Nordkyn, in 71° 8' N., the southernmost, Lindesnes in 57° 59' N. Hence the south extremity of Norway lies in the same latitude as Dornoch firth (Scotland) and of mid-Kamchatka. The most western island, Steinsö, lies off the mouth of the Sogne fjord (4° 30' E.), and the easternmost point is Hornö (31° 10' E.) near Vardö. The direct length of Norway (south-west to north-east) is about 1,100 miles. The extreme breadth (about 61° N.) is 260 m.; the average is about 60 m., but the Swedish frontier approaches within 5 m. of a head-branch of Ofoten fjord, and the Finland frontier within 22 m. of Lyngs fjord. The length of the coast line is difficult to estimate; disregarding indentations it is about 2,110 m., but including the fjords and greater islands it is probably 12,000 miles. The total area was estimated at 124,964 sq. miles (1920).

Physical Features.—The main highland mass of the whole Scandinavian peninsula is a very much eroded plateau which, probably on account of forming, in the main, the watershed between the rapid western rivers and the normally longer and slower eastern rivers of Sweden, has received the name of Kjölen (the Keel). Although the plateau as a structural feature may be considered to extend from south-west Norway to North cape and even beyond into Spitsbergen, yet its ridge-like character is most marked where it coincides most closely with the Swedish boundary, *i.e.*, north of 63° N., and there is a desirable tendency to restrict the name to this portion. The high plateau consists of early Palaeozoic rocks which represent one of the oldest structural elements in Europe. An Archaean zone stretches along the west coast from Bergen to Hammerfest interrupted towards the north by overlying patches of Palaeozoic deposits. Gneiss predominates, but other crystalline rocks occur subordinately. The Lofoten islands consist chiefly of eruptive granite, syenite and gabbro. South of a line drawn from the head of the Hardanger fjord to Lake Mjösen is another great Archaean area.

A line drawn from the Nase to the North cape coincides roughly with a marked change in the character and structure of the Palaeozoic rocks. East of this line even the Cambrian beds are free from overfolding, overthrusting and regional metamorphism. They lie flat upon the Archaean floor, or have been faulted into it in strips, and they are little altered except in the neighbourhood of igneous intrusions. West of the line the rocks have been folded and metamorphosed to such an extent that it is often difficult to distinguish the Palaeozoic rocks from the Archaean. They form in fact a folded mountain chain of ancient date which has subsequently been worn down and then faulted up. No volcanic rocks of recent date are known in Norway. This faulting largely accounts for the almost unique character of the river and coastal topography of Norway. Differential erosion, partly glacial, has caused many of the highland masses to form prominent mountain summits not only on such islands as the Lofoten chain, but on the plateau itself. The average height of Norway is probably about 1,600 ft. and may be compared with approximately 1,000 ft. for Europe as a whole. This high figure for Norway is not dependent so much on the height of individual summits as on the absence of extensive lowlands; south-east Norway is the lowest part and even this is of a hilly nature. In the area north-west of the Norway-Finland boundary a few peaks reach slightly

over 4,000 ft., but immediately south of the junction of the three countries the general height increases considerably, though the most lofty summits are entirely Norwegian only in the extreme north of this area. (See SWEDEN.) Here Jaeggesvarre (6,283 ft.) lies between Lyngs and Uls fjords, and Kistefjeld (5,653 ft.) provides right bank water for the Barduelv, which runs westward north of Torneträsk. Sulitjälma (6,158 ft.) lies actually on the frontier. Nearer the coast and centred approximately on the Arctic circle is the great icefield of Svartisen (see GLACIERS), through which projects Snetind nunatak (5,246 ft.). The only important peaks immediately south of this are Okstinderne (6,273 ft.), and the rather better known Stora Börgefjeld (5,587 ft.). At about Lat. $63\frac{1}{2}^{\circ}$ N. is the southern limit—Trondhjem fjord—a remarkable depression which runs for upwards of 200 m. south-west to north-east dividing the narrowest part of Norway into almost equal eastern and western strips. Its exit is at Saltfjord (near Bodö) and it is characterized by numerous rivers, some draining north, others south; the depression is of the greatest importance for internal communication and for future railway routes. Due east of Trondhjem fjord the plateau is lowest and narrowest, again offering a relatively easy communication route already utilized by a railway. Also from this fjord southwards is a valley line and a railway route to the Upper Glommen valley and down this to Oslo. South of the Trondhjem "narrowing" the plateau swings westwards, becoming higher, wider and more definitely Norwegian. The Sogne fjord (61° N.) and its branches reach out towards a giant horseshoe of the highest ridges in Norway; northwards are the Jostedalbrae; the Jotunheim lies north and north-east; the Hardanger fjeld is south-east and the Voss lies south. North-east of the Jotunheim beyond the deep cleft of Gudbrandsdal and its north-west counterpart the Romsdal, is the Dovre fjeld, and south-east of this, the Rondanefjeld. South of the Hardanger fjeld, beyond Hardanger fjord, is the lake-sprinkled Hardanger Vidde, the most expansive tract of open high plateau in Europe; south-eastwards this plateau merges into the lower hummocky Telemark mountains which are drained south and south-east to the Skagerak. The most lofty summits occur in the Jotunheim with Galdhöpiggen (8,097 ft.) as the highest Norwegian mountain, though if the 100 ft. or so of snow on the top of Glitterkind is included, then this reaches to 8,140 ft.; nearly 30 peaks in all exceed 6,500 ft. in the Jotunheim mass. The other mountain areas are lower, though the Dovre fjeld and the Rondanefjeld have Snehaetta (7,550 ft.) and Rundvashögda (6,890 ft.) as their respective summit masses.

Coast.—The Norwegian mountains fall abruptly to the sea, and the coastline almost throughout is cliffbound. The land features are continued as numerous islands, estimated at 150,000, which fringe the mainland. This island fringe, occurring also in a modified form along the Swedish coast, is, in Norway, termed the *Skärgård* (skerry-fence). This fringe and the fjord-coast are most fully developed from Stavanger nearly as far as the North cape, but only between Stavanger and Flekkefjord can the coast be considered smooth and moderately free from islands. Here, particularly north of Egersund, a narrow lowland, abundant in peat bogs, is fringed by a flat, open coast, dangerous to shipping. The channels within the island line are of incalculable value to a people largely dependent on coastwise navigation. In fact, the voyage northward from Stavanger may be made in quiet waters almost throughout. Only at rare intervals, as off the port of Haugesund, or when crossing the mouth of some large fjord, need the open sea be encountered. At some points large steamers follow the carefully marked deep-water channel, between cliff edges which seem to overhang the vessel on either side. Small vessels, fishing or trading between the fjord-side villages, navigate narrow ramifying "leads" (*leder*) where the sole danger is the tidal current, often exceedingly strong. The largest island is Hindö (Lofoten and Vesteraalen group), about 850 sq.m. in area.

Glaciers.—The relatively insignificant Norwegian glaciers of to-day have unimportant effects compared with the glaciation consequent on the presence of the enormous ice-fields in the last Ice age. To these latter glaciers is owed much of the smoothing

of islands and the fjord character of the coast. The rounded nakedness of the mountains, the U-shaped valleys, the shelf-like ledges over which the rivers plunge, to produce the "white coal" of Norway, and the pockets of finely divided fertile soils in rock basins are all direct legacies. The level terraces and raised beaches which exist on some of the coasts and prove such desirable sites for settlement are mainly composed of glacial debris once deposited below sea-level but now elevated by land oscillation. To-day Norway still contains the largest European icefield—the Jostedalbrae. This is some 400–500 sq.m. in extent: from it glaciers run to within 150–200 ft. of sea-level. Jotunheim, though glaciated, has the ice-cap broken by deep valleys, also as it lies further east the precipitation is lower and the summer temperatures higher—two factors seriously affecting the size of ice-caps. Between Hardanger fjord and its branch, Sörfjord, is Folgefond—110 sq.m.—and the most southerly considerable area in Norway. Second in point of size to the Jostedalbrae, but not inferior in interest, is Svartisen—230 sq.m. in area, from which glaciers descend almost to sea-level. In about lat. 70° a small glacier, the Engabrae, actually enters the sea in Jokulfjord (a branch of Kvenangfjord) and gives birth to miniature icebergs. The Seiland glacier (46 sq.m.), on the island of the same name south of Hammerfest, is the most northerly Norwegian example. The snow line in Norway varies in height with aspect and amount of precipitation, but it is everywhere fairly low—ranging from below 3,000 ft. in Seiland to slightly above 5,000 ft. in south Norway.

Many islands, chiefly northern, are of great elevation; thus the jagged granite peaks characteristic of the Lofotens reach about 4,000 feet. Other interesting islands are Hornelen, near the mouth of Nordfjord, rising nearly sheer for 3,000 ft. above the sea; the well-named Torghatten ("the market hat"), north of Namsos, completely pierced, 400 ft. above the sea, by a vast natural tunnel, which on occasion reaches upwards of 200 ft. in height and 80 ft. in width; the quaintly shaped small Hestmannö ("horseman island"), intersected by the Arctic circle, justly named from its form. Bare rock is the dominant feature of the coast and islands, save where a few green fields surrounding a farmstead occupy a miniature level terrace. The oscillation of the land relative to sea-level is illustrated by marine terraces, 600 ft. above the present sea-level, near Trondhjem, and by the numerous former beach lines of north Norway, which are occasionally in pairs at different heights. Nevertheless, at some points (as on the Jaderen coast) glaciated "giants' kettles" may be observed even below the level of high tide thus indicating the greater level of the land towards the close of the Glacial epoch.

Fjords.—Oslo fjord, opening from the north angle of the Kattegat and Skagerak, differs from the great fjords of the west. Its shores are neither high nor precipitous. It is shallower, wider, and is surrounded by the most extensive lowland in Norway. It is studded with numerous small islands. Thence, past Lindesnes, to Bokn fjord there are many small fjords, 300 fathoms in extreme depth, but even the intermittent inner lead which can be traced to Flekkefjord ceases to exist beyond. Bokn fjord is broad and island-studded, but throws off several inner arms, of which Lyse fjord, due east of Stavanger, is 25 m. long and half a mile wide, with precipitous walls. It is the most beautiful and mysterious fjord in south-west Norway. Hardanger fjord (355 ft. extreme depth) penetrates the land for 70 m. and is frequently visited, for it lies near to shipping routes which converge on Bergen, but its beauty is exceeded by that of Sogne fjord and Nordfjord farther north. Sogne is the largest and deepest fjord of all; its head is over 100 m. from the sea; its maximum width scarcely exceeds 2 m., and the main channel is 500–660 fathoms deep. Some of the northern arms intersect the snow-clad Jostedalbrae, and their dark blue waters have a surface layer showing a milky tinge imparted by glacier-fed streams. Nordfjord (340 ft. in extreme depth) touches the northern side of the Jostedalbrae and is popular with tourists. Stor fjord opens inland from Aalesund; it is over 70 m. long and is wild and imposing. Trondhjem fjord (300 ft. in extreme depth), the next great fjord northward, broadens inland from a narrow entrance, but lacks

SCENES IN NORWAY

1. Hammerfest, 70° 35' north latitude (the midnight sun); a tourist town well within the Arctic Circle. 2. Norangsfjord in the northwest, showing the characteristic ribbon of water and glaciated slopes. 3. Aalesund, port of call on an island near entrance to Storfjord. 4. The Hardanger district, with the Buarbrae Glacier in the background. 5. Geirangerfjord; the vessel in the channel indicates the scale of the view. 6. Trömsø, important port

and tourist centre more than three degrees north of the Arctic Circle. 7. Roa near Oslo; a typical winter landscape of south Norway. 8. Local costumes of peasant farmers in south Norway. 9. Farm on the Esefjord, Sogne district. 10. 13th century Viking storehouse. 11. 11th century wooden church at Fantoft near Bergen

grandeur as the elevation of the land is reduced at the Trondhjem "narrowing." Immediately north of Trondhjem, the fjords, though long, are not so extensive and the coastline loses its grandeur, but north of Salt fjord, which lies beyond the great Svartisen icefield, the scenery is unsurpassed. Salt fjord is connected with Skjerstad fjord by three narrow channels, where the water, at ebb and flow, forms powerful rapids. The Lofoten islands and Ves-

teraaen are separated from the mainland by the Vest fjord (340 ft. deep), which is continued inland by Ofoten fjord, on which is situated Narvik, the railhead town for the line from Sweden. The main fjords north of Vesteraalen have a general northerly direction; among them is Lyngs fjord near Tromsø, with high flanking cliffs. The softer and looser schists are more prevalent in the north, hence the fjords are wider, branched and interlaced, particularly in Finmark. The Alte fjord (225 ft. extreme depth) is remarkable for the vegetation on its shores. From Lofoten north there is a chain of larger islands: Senjen, Kvalø, Ringvadsø, Sorø, Seiland and Magerø, thus extending to the most northerly point, but hereafter the Skärgård ends abruptly. The coast to the east is of widely different character; flat mountain wastes descend precipitously to a sea destitute of islands, save Vardø, with two low islets at the eastern extremity of Norway. The chief fjords are Porsanger and Tana, opening north, and Varanger opening east. North of the last fjord the land is low and the landscape monotonous; on the south of it a few islands and branch fjords break the smoothness of the coast line.

Hydrography.—Both in respect of rivers and of lakes Norway is well supplied. As a rule, the rivers are short and have a small basin; and the lakes are long, of little area, but of great depth, for many give soundings showing their beds to be well below the present sea-level. In this connection, Mjösen, the largest Norwegian lake, 140 sq.m. in area at an altitude of 397 ft., has a maximum depth of 1,482 ft. (nearly 1,100 ft. below sea-level); Tyrifjord (alt. 207 ft., area 51 sq.m.) has its maximum depth 700 ft. below sea-level; Tinsjön (alt. 605 ft., area 17½ sq.m.) with its bed over 800 ft. below sea-level; but the most remarkable case is Hornindalsvand, 6 m. beyond the head of Nordfjord—20 sq.m. in area, 180 ft. alt.; its maximum depth is 1,414 ft. below sea-level. Many of the high level lakes are also of great depth, e.g., Bydinsjön—area 17½ sq.m., alt. 3,485 ft., greatest depth 705 ft. The total number of lakes, tarns and pools is very high: in all they probably cover nearly 2,950 sq.m. (2½% of entire country). In many cases the low-lying lake near the head of a fjord is separated from sea water by a narrow but steep-sided neck of land which on further land subsidence would resemble the submerged sill which is so characteristic of the underwater topography of the fjords. The majority of the river valley lakes resemble mere expansions of the width of the river, and possess strong currents, hence their value for internal transport is, on the whole, less important as routes for water-borne traffic than for providing through lines for land communication in the difficult mountainous sections of the country. Stora Le on the

frontier in the south-east is somewhat exceptional, for it provides a definite water-transport link between a canal system of Norway and one of Sweden. The majority of the rivers run swiftly between steeply sloping valley walls, particularly in their upper and middle courses, and are there of little or no value for any form of navigation though they are extremely useful as gigantic flumes for the gravity carriage of timber. They are utilized as water-heads for hydro-electric schemes by which nearly 1,400,000 horse-power are now being developed and used.

The unexploited sources are still enormous, over 10 million horse-power, and the people are fully aware of this source of natural wealth. Its development becomes easier on account of the numerous rapids and falls which characterize the rivers. As Norway also fully realizes the financial value of her remarkable scenery and of her anglers' haunts, the mode of utilizing this smokeless-power in the industrialization of any area will be given much thought. A limiting factor in the "white coal" schemes is the seasonal character of many Norwegian streams which run low in winter on the freezing of their upper courses and rise rapidly during the period of maximum rainfall—here the lakes are of supreme value as safety-valves controlling spring thaw-water and autumnal rain water. Nevertheless, disastrous floods are not unknown. The lakes themselves in the north and interior freeze for varying periods each year, but in the south, where the majority of the large lakes are situated, it is only during very severe winters that these reservoirs become icebound. In a land where rivers possess so many and so varied interests selection becomes difficult.

The principal river of Norway is the Glommen, about 400 m. long, which rises about 2,300 ft. above sea-level in the highlands south of Trondhjem fjord. It is a swift stream with numerous falls, and even within 8 m. of its mouth, in Oslo fjord, there is a series of seven falls of which Sarpfos (60 ft. high and 164 ft. wide) is the best known. The river, which runs mainly north to south, drains about 16,000 sq.m., pierces the richest timber area and provides an important railway route from Oslo to Trondhjem. Above Öieren (area 36 sq.m.) the largest lake of the numerous ones in its course, the Glommen makes a remarkable bend (at Kongsvinger). Here, in post-glacial times, the river which formerly ran due south to Väner lake (Sweden) made a sudden swing to the west capturing the upper waters of the Laagen, formerly an independent stream. (The old bed still carries occasional flood water from the Glommen to the lake.) The Laagen, 200 m. long, has, for a Norwegian river, a large upper basin receiving water from the Jotunheim and the Dovre fjeld. Its sources lie near Romsdals fjord, for which it is providing the following railway route direct from Oslo: along its lower course (River Vorma) past the shores of Lake Mjösen up the Gudbrandsdal, over the water parting and down Romsdal—another railway line links Trondhjem with the head of Gudbrandsdal. This last name illustrates a common practice, in Norway, of using different names for a river in its different courses, and different names for a river and for its enclosing valley—the valley name being also frequently employed for surrounding districts. Of the other important streams entering Oslo fjord, the Tistedalelv reaches its eastern seaboard after draining through a series of long, narrow lakes connected by rapids; the Dramselv (Drammen), a large river with a considerable basin extending into Hemsdals fjeld, Valdres and File fjeld, enters on the western sea-board. Its upper tributaries, the Randselv and the Aadalselv (plunging over Hønefos), unite to form the Storelv which expands into the Tyrifjord lake. Below this the real Dramselv begins and receives, on the right bank, the Hallingsdalelv which flows through Lake Kröderen—all these valleys afford important but not easy routes, and, though the rivers are not navigable for any long stretches yet steamers are employed on the lakes. Numerous streams drain southwards from the plateau and lake district of Hardarger Vidda, one of these, the Numedalslaagen (nearly 200 m.) is noted for its falls, e.g., Hammerfos and Labrofos, and for its wealth in salmon. From the Telemarken district, runs the Skienelv (150 m.) flowing through the very deep Tinsjön and the slightly larger, deep Nordsjön; the former lake receives the river Maane, on which is the famous Rjukanfos (415 ft. high).

The most notable falls occur in the courses of the shorter and more rapid western streams. Some of the most striking, in order from the south, are: Vöringfos (535 ft.) on the Bjoreia and Skjaeggedalsfos (525) on the Tyssaa—these two are in the Hardanger fjord area. Around Sogne fjord are several, of which Vettisfos (850 ft.) on the Morkedöla is probably the most interesting. The famous "Seven Sisters Falls" are in a branch of the Storfjord, while the Namsenelv (85 m.) a popular salmon river entering Namsenfjord has Fiskumfos (105 ft.) and several others. The Arctic ocean rivers have gentle gradients, occasional rapids but no important waterfalls. Two longer ones are the Altenelv (112 m.), which drains into the Alte fjord, but unfortunately its valley affords no route of importance and the Tanaelv (120 m. long—third longest river of Norway) which drains a considerable area in Norway and Finland, but the absence of lakes results in summer floods increased by the presence of ice dams. The lower river is wide (about 2,000 yd.) and tidal for 6 or 7 m., and is ascended by small vessels. River boats are used along certain river stretches below and above the Storfos rapids which occur about 45 m. from the mouth of the river and have a fall that averages 23 ft. in 1,000 yards.

Flora.—The forests of Norway consist chiefly of conifers. The principal forest regions are in the south-east and south. In the Trondhjem area and in Nordland there are extensive forests of pine and spruce with the pine on the drier, higher, and less congenial parts. In south-east Norway the conifer tracts extend from sea-level to 2,500 to 3,000 ft.; in the inland parts of the Trondhjem region the upper limit sinks to 2,000 ft.; while on the coast the upper limit is only from 600 to 1,200 ft.; farther north the spruce disappears and the pine limit falls to 700 ft. about 70° N. Above and north of the conifers is the birch belt; next follow various species of willows, and the dwarf birch, and last of all, before the snow-line, the lichen belt, in which the reindeer "moss" is always conspicuous, but a few flowering plants, shrubs and trees of the willow belt sometimes extend close up to the snow line. Even among the conifers there is a sprinkling of other trees—lowland birches, aspens and rowans in the high north, while in the south and less elevated districts the lowest zone of forests includes the ash, elm, lime, oak, beech and black alder; but the beech is much rarer than in Sweden and, in fact, flourishes only near the Skagerak; here and elsewhere the extreme coast region is destitute of forest. The richest flora is found in the inland fjord valleys, but the Dovre fjeld is the district in which Arctic flora may be studied in great variety and within narrow limits. Marine flora is very finely developed on the coastal banks.

Fauna.—The great forests are still the haunt of the bear, the lynx, and the wolf. Bears are chiefly restricted to the uplands north of Trondhjem, and the cutting of forests has limited their range to the least accessible highlands. The wolves decreased very suddenly in south Norway about the middle of the 19th century, probably owing to disease, and during the last half-century have continued to decrease in the north; but they are still abundant in Finmark, and are the worst enemy of the reindeer. The elk occurs in the eastern forests, and near the coast in the Trondhjem district, but is now becoming rare. The red deer is confined chiefly to the west coast districts; its principal haunt is the island of Hitteren, off the Trondhjem fjord. It is usually regarded as a survival of the oak age. On the high fjelds are found the wild reindeer, glutton, lemming and the fox. The wild reindeer, which occurs in Finmark has decreased, though large tame herds are kept by the Lapps. The lemming is noted for its curious non-periodic migrations; at such times vast numbers of these small animals spread down country, even swimming lakes and fjords. They are pursued by beasts and birds of prey, and even the reindeer kill them for the sake of the vegetable matter they contain. Hares are very common all over Norway up to the snow line. The beaver, formerly widespread, decreased seriously, but strict protection has saved it, and it is fairly plentiful in the south Norway valleys.

Game birds are fairly abundant in most districts. Black grouse are widely distributed in the region of conifers and birches south

of Finmark. Hazel grouse are found mainly in the spruce forests of the south-east and east, and fairly generally in the north, as are capercaillie, but the former is lacking in the west, and the latter is found near certain fjords only. Woodcock and snipe are moderately plentiful. The partridge, an immigrant from Sweden, occurs principally in the east and south-east. A severe winter causes a marked scarcity of them. A very large proportion of the Norwegian avifauna consists of migratory geese and ducks, various birds of prey, golden plover, etc. These birds leave in autumn by three well-defined routes—one from Finmark into Finland, one by the Cristiania valley, and one by the west coast, where they congregate in large numbers on the lowlands immediately south of Stavanger; but certain high Arctic birds as the king-eider, Spitzbergen guillemot and the little auk move on to the north Norway coast from higher latitudes at the end of summer. The Arctic type of bunting, the snowy owl, and the rough-legged buzzard are exceedingly numerous. In some localities the puffin and kittiwake form great colonies (*fugleberge*, bird cliffs).

The common seal is very frequent; and Arctic seals visit the northern coasts; among these the harp, or Greenland, seal is believed to be particularly destructive to the fisheries. A large number of the best European food-fisheries occur along the coasts, including cod, herring, mackerel, sprat and flat-fish. Various species of whales visit the coast; the most important is the rorqual, or finner—the largest is the blue whale, which appears off the coast of Finmark from June to August. Other finners are the *true finner* and the smaller fish-whale. The most important of other types of whales are the bottle-nose, the humpback and the caaing whale. Of freshwater fish the *Salmonidae* are by far the most valuable. Next to these, perch, pike, grayling and minnow are most common.

South Norway is richer than west Norway in insects, and north Norway has numerous characteristic Arctic types.

Norway is much frequented by British anglers. The *Salmonidae* have penetrated considerable distances inland, and though the trout is the only one to reach many of the upland lakes yet it is very abundant there. (Most of the owners of water rights have a full appreciation of the value of good fishing to sportsmen, especially when netting rights are given up for the sake of rod-fishing.)

Climate.—The striking and unique feature of the climate of Norway is the presence of the largest positive temperature anomaly on the surface of the globe, which results in such unusual conditions as average temperatures within the Arctic circle which are higher than those of places farther east and 20° of latitude farther south. Again, Hammerfest, a thriving settlement of over 3,000 inhabitants, is actually north of King William's Land, which witnessed the tragedy of the Franklin polar exploration party. This temperature anomaly is consequent on the warm water and air-drift across the Atlantic ocean on to the shores of Norway. February is the coldest month, and south-east Norway then has a mean temperature of below 32° F (Oslo 23.9°), but the coldest parts in this area are the Glommen valley, between Tönset and Röros (near the Swedish border). At the latter place (altitude 2,067 ft.) the February mean is 12.2° and an absolute minimum of approximately 80° F of frost has been recorded. Even this intense cold has been exceeded at stations near the Norway-Sweden boundary in Lapland. A somewhat unusual phenomenon is that lower-lying stations occasionally show lower winter averages than upland stations near to them; e.g., Tönset 11° average against Röros 12.2°. Tromsö, Skudenes (on an island north of Stavanger) and Bergen have averages of 25.0°, 34.5° and 33.6° respectively. The number of days on which frost occurs varies between 60 at Skudenes and 240 in certain parts of Finmark; North Cape has about 190. The fjords are not penetrated by the cold water from the open ocean and are always ice-free except for patches along shallow coastal stretches during unusually severe winters. Summer temperatures range between slightly below 50° in the extreme north (Tromsö 51.8° F July average), and 60.6° at Oslo in July. Röros, with much greater altitude, has 52.2° average in the same month. The south-east of Norway is the warmest part in summer. At Bergen and Sku-

denes the warmest month is August (57·9° average for each). Absolute maxima are high, and the following have been recorded: Skudenes, 84°; Bergen 86°; Oslo 93°; and even Karasjok, in Lapland, has recorded 88°. The annual range increases from west to east generally and from south to north along the coast.

Though the south-west wind is usually prevalent over Norway and very marked in summer yet the winter high pressure area causes outflowing winds. These may be roughly classified thus:—

In Winter	(Skagerak) N.E.	West Coast S. and S.E.	North Coast S.W.
--------------	--------------------	---------------------------	---------------------

Gales are frequent on the west coast, averaging three to four per month in winter and about one to two per month in summer. In the interior and east gales are comparatively rare. Gales from the south-west bringing rain are the most common; next in frequency are gales from the north-west bringing snow. Calm weather is rare on the west coast but frequent in the interior. December and January are the stormiest months. Hailstones and thunderstorms are not of frequent occurrence in any part of Norway.

The number of days on which rain or snow falls is greatest on the north-west and north coasts, least in the south-east districts and the interior of Finmark. In the former area, precipitation occurs on about 200 days in the year. On Dovre fjeld and the south-east coast the average is about 100 days. Snowfall occurs least frequently in the south (e.g., at Mandal, 25 snowy days out of 116 on which precipitation occurs), increasing to 50 at Oslo, and Dovre fjeld, to 90 at Vardö, and to 100 at the North cape. Hence in the north and in the upland tracts, snow occurs at least as frequently as rain. Snow may fall in any month on the coast as far south as the Lofotens. The amount of precipitation exceeds 100 in. per annum in the mountains a few miles from the coast north and south of Sognefjord. On the outer islands there is a slight decrease; inland the decrease is rapid and great. In the extreme south of the country the average is about 39 in. There is a diminution eastward along the north coast and a further rapid decrease towards the northern interior, where the average is 16 in., but strongly marked local variations are observed.

The amount of cloudiness is great. The coast of Finmark has over three cloudy days to one clear day; in the interior of the country clear and cloudy days are about equally divided. Summer fog is frequent on all coasts but fog is rare in winter, though occasionally experienced in the south-east. Sometimes, in severe winters, a frosty fog ("smoke-frost") appears on the west coast fjords, and is caused by the piercing cold land wind passing over the relatively warm water.

The "Midnight Sun."—Part, at least, of the sun's disc is above the horizon at the North cape continuously from May 12 to July 29, and at Bodö, in lat. 67° 17' N., from July 3 to July 7. Even at Trondhjem there is practically no night from May 23 to July 20, while the long twilight gives the extreme south of Norway no real darkness from the end of April to the middle of August. In winter, on the other hand, the sun does not rise above the horizon at the North cape for over two months and there is only a twilight at midday. In the extreme south mid-winter night is 17½ hours long.

Population.—The resident population of Norway on Jan. 1, 1927, was estimated at 2,788,893. The table below shows the area and population of each of the 18 *Fylker* (counties) and of the two largest towns, according to the decennial census taken in 1920:—

District	Population 1920	Area in English sq.m.
Southern—		
Östfold	160,128	1,614
Akershus	170,062	2,050

This gives an average population per square mile of but 21·2, hence, Norway, on average, is the most thinly populated political unit in Europe. The most sparsely populated English county, Westmorland, had 83½ persons per square mile in 1921. This was exceeded only in the fylker of Vestfold, Östfold and Akershus with 137·6, 99·2 and 87·4 respectively. The next in order was Rogaland with 47·2. The first three are the smallest Norwegian counties and are in the immediate neighbourhood of Oslo. Rogaland is in the extreme south-west of the country. A vast area practically uninhabited, save in the north by nomadic Lapps, reaches from the extreme north as far south as the middle of Hedmark, apart from small local patches of denser population such as those in the outer Lofoten islands and across the Trondhjem depression. The most northerly fylker, Finmark, is the least thickly populated (2·4 per square mile); in many highland regions habitations are hardly less scanty than in the lowland regions of the extreme north. The vast majority of the population dwell by the coast and fjords. In 1920, 1,864,371 were living in rural districts and 785,404 in towns. Of the chief towns of Norway, Oslo, the capital, had a population in 1920 of 258,483, Bergen of 91,443, Trondhjem of 55,030, Stavanger of 43,778, Drammen of 26,204. The towns with populations between 20,000 and 15,000 were the ports of Haugesand, Alësund, Kristiansand, Skien, Fredrikstad and Kristiansund.

The population of Norway in 1801 was less than one million; the increase was very marked from 1815 to 1835, after which rates of increase gradually diminished. The second half of the century, down to 1890, was the period of heaviest emigration, chiefly to the United States of America. Emigration slackened in the last decade of the 19th century, during which period the movement from rural districts to towns, which had decreased from about the middle of the century, revived. The number of Norwegians abroad is probably about 400,000. In 1926, 9,326 emigrated (6,497 to U.S.A. and 2,570 to Canada). The Lapps, 19,328 in 1920, called Finns by the Norwegians, were confined especially to Finmark, and are estimated at about 1% of the population. There were also 7,309 Finns, whom the Norwegians call Kvoener. Of Lapp-Finns there were 2,814. The excess of births over deaths, about 1·8 to 1 in 1926, is much above the European average; the death-rate is unusually low. The number of marriages is rather low, the average marriage age being high. The percentage of illegitimacy, about 6·7% of total births in 1926, has shown a recent decrease, but is still above that for many European countries. The preponderance of females over males (1,359,306 to 1,290,469 in 1920) is partly accounted for by the number of males who emigrate, whilst the higher mortality of males is traced in part to the dangers of a seafaring life.

BY COURTESY OF NORWEGIAN GOVT. RAILWAYS
WOMEN DRESSED IN THE NATIVE
COSTUME OF GUDBRANDSDAL AND
SETESDAL

Government.—Norway is a constitutional and hereditary monarchy. The Constitution rests on the fundamental law (*Grundlov*) promulgated by the National Assembly at Eidsvold on May 17, 1814, and altered in detail at various times, particularly after the dissolution of the union with Sweden on June 7, 1905. The executive is vested in the king, who comes of age at 18. His authority is exercised through a council of State consisting of a prime minister (*statsminister*) and at least seven other councillors (*statsraader*), who are the heads of finance, church and education, justice, defence, public works, commerce and industry, agriculture and social affairs. The prime minister is normally in charge of foreign affairs. The king has the command of land and sea forces and makes all appointments, but contrary to the custom in most other countries the king has no power to dissolve the parliament (*storting*). The 150 members of this legislative body are elected directly by the people, divided into electoral divisions in such a manner that the towns are represented by one-third of the total members. Elections are direct, proportional, and take place every three years. The franchise is extended to all Norwegian citizens, male and female, who have completed their twenty-third year and have resided five years in the country. There are certain mild legal conditions of citizenship. A parliamentary member (*stortingsmand*) must possess the franchise in his constituency; must have resided ten years in the country; and must not be less than 30 years of age. Women, since 1915, have been entitled to membership of the King's Council, but up to 1928 none have been so appointed. The *storting* meets at Oslo on the first weekday after Jan. 10 each year and remains assembled as long as may be found necessary. After the opening the assembly divides itself into two sections, the upper (*lagting*) consisting of 38 members and the lower (*odelsting*) of the remainder. The inspection of public accounts and revision of the Government belong exclusively to the *odelsting*, which also first receives each new bill; if passed there it is sent to the *lagting*, and if carried there it is sent forward for the royal assent. If the *odelsting* and *lagting* do not agree, a joint session is held and the fate of a measure is decided by a two-thirds majority of the combined sections. The king has a veto, but if a vetoed measure is passed unaltered by three successive parliaments it becomes law *ipso facto*. Members of parliament are now paid 6,000 k. per annum and their travelling expenses. Parliament has both legislative and administrative authority, it also fixes taxation, and has control of the members of the Council of State, who though they may take part in discussions may not vote in the *storting*.

Justice.—An outstanding characteristic of Norwegian legal procedure is that civil cases are usually brought first before the town or district commission of mediation (*forliksraad*) from which an appeal lies to the local inferior courts, which are also tribunals of first instance, and are worked by judges on circuit and by assessors. There are three superior courts of appeal (*overrettene*) at Oslo, Bergen and Trondhjem, and one supreme court (*höiesteret*). Criminal cases are tried either in jury courts (*lagmandsret*) with three judges and 10 jurors or courts of assize (*meddomsret*) with one judge and two assistant judges. The first is for more serious offences; the second deals with minor offences and is a court of first instance. Military crimes are dealt with by a military judicial organization. Finally, there is a High Court of the Realm (*rigsret*) composed of the *lagting* and the ordinary members of the *höiesteret*, before which members of parliament, the Government, etc., are tried for misdemeanours committed in their public capacity.

Local Government.—The country is divided into 20 districts, viz., 18 counties (*fylker*) (see *population*) and the cities of Oslo and Bergen. Other towns are formed into 65 communes, governed by representatives, from whom a council of one quarter of the total representatives is elected by themselves; 672 rural communes (*herreder*) are similarly administered, and their chairmen form a county council (*fylkesting*) for each county. At the head is the *fylkesmann*, the county governor. The electoral system for local councils is the same as the parliamentary system, and has been extended to women under similar conditions.

Religion and Customs.—The endowed State religion, to which the king must conform, is Evangelical Lutheran. In 1920 there were but 71,062 dissenters, though all Christian sects except Jesuits are tolerated. The king nominates the clergy of the Established Church.

Norway is divided into seven bishoprics (*Bispedømmer*), Oslo, Hamar, Khristiansand, Bergen, Trondhjem, Tromsø, and Stavanger; and these into 91 archdeaconries (*prostier*) with subdivisions into 514 clerical districts (*prestegjeld*), parishes, and sub-parishes. The clergy take a leading part in primary education, which, in spite of the difficulties arising in a sparsely populated country, reaches a high standard.

Down to the middle of the 19th century drunkenness was a strongly-marked characteristic of Norwegians. A strict licensing system was then introduced with success. Local boards were given a wide control over the issue of licences, and in 1871 incorporated societies (*samlag*) on the Swedish model were introduced to monopolize and control the retail trade in spirits. Their work practically ceased when the existing prohibition came into force. A plebiscite in 1919 gave 487,999 votes for and 304,297 against prohibition. On account of existing and potential trade treaties with France, Spain and Portugal it was decided that the plebiscite should have an advisory force. At present all production and trade in spirits as beverages is prohibited, and the wine monopoly severely controls the sale of wine and beer even in those districts where the local municipal authorities have issued a licence, without which sale is impossible.

In Norway there is a strongly individual national character, as is shown in the case of modern music and painting, combined with conservatism of ancient rites and practices. Such peculiar customs as those associated with weddings, lighting of the midsummer fires and the attendant celebrations still survive. In coastwise trade and fishing, high-prowed square-sailed boats, the direct descendants of the Viking vessels, are still frequently employed. Examples of the ancient farmstead, composed of a group of single-chambered wooden buildings, are preserved, and mediaeval ornamental woodwork remains important. Wood is the principal building material except in some larger towns. In the rural areas fires have left few really old domestic buildings, but the preservation of ancient wooden houses elsewhere makes several of the Norwegian towns peculiarly picturesque. Norway retains a few of the peculiar richly carved small wooden churches (*stavekirke*) dating from the 11th to the 14th century. They have high-pitched wooden shingle roofs rising in tiers so as to give the building something of the form of a pyramid. The roofs overhang so deeply (to offer weather-protection to the wooden walls) that the lowest often shelters a species of external colonnade. The most famous of these churches is that of Borgund—19 m. from Laerdalsören; another fine example is at Hitterdal on the Kongsberg Telemark road. There are also a few Romanesque and Gothic stone churches. In some of these the influence of English architecture is clear, as in the magnificent metropolitan cathedral of Trondhjem, and the nave of Stavanger cathedral. A good example of the smaller stone church is at Vossevangen, on the Oslo-Bergen railway, and there are several of Late Romanesque character in the Trondhjem district. Remains of pure Early English work are occasionally found, but the later Gothic styles were not developed to any extent in Norway.

BIBLIOGRAPHY.—A valuable publication, including an extensive bibliography, but now somewhat out of date on the economic side, is *Norway* (official publication for the Paris Exhibition), Eng. trans., Christiania (1900). Other authoritative reference works include A. N. Kiaer and others, *Norges Land og Folk* (Christiania, 1885-1916); 20 district volumes have appeared, but the work has been suspended in an incomplete condition. *Statistisk Aarbok for Kongeriket Norge* (Oslo, annual). In addition to this annual summary, the Government issues publications frequently on the work of various State Departments. Reports on Norway are also issued in Foreign Office Reports (annual, London), and the Geographical Section of the Intelligence Dept., Admiralty, also issued a *Handbook of Norway and Sweden* (H.M.S.O., 1920).

A general book of considerable value is Hans Reusch, *Norges Geografi* (Christiania, 1915-17). Other books are Y. Nielsen, *Reisehaabok over Norge* (10th ed., Christiania, 1903), various guidebooks in English, e.g., Nielsen (Christiania, 1908); Baedeker (1912), Mur-

ray (1904), Ward Lock and Co. (1927); S. C. Hammer, *The Norway Year Book* (No. 1, 1924, Christiania); and *Things Seen in Norway* (London, 1926); H. L. Braekstad, *The Constitution of the Kingdom of Norway* (London, 1905); F. Nansen, *Norway and the Union with Sweden*, and supplementary chapter, separate (London, 1905). K. Gjerset, *History of the Norwegian People*, 2 vols. (London and New York, 1915); G. G. Hardy, *Norway* (London, 1925). Travel and sectional books include: Beckett, S. J., *Norway and its Treasures* (London, 1914); and *The Fjords and Folk of Norway* (London, 1915); W. C. Slingsby, *Norway, the Northern Playground* (on mountaineering) (Edinburgh, 1904); *Jahrbuch des Norwegischen Meteorologischen Instituts* (Christiania); H. Mohn, "Klima Tabeller for Norge," in *Videnskabselsk. Skrifter* (1895 seq.).

See also *Board of Trade Rep. on Production and Consumption of Alcoholic Liquors* (London, 1899). Finally, the current volume of the *Statesman's Year Book* (London, annual), normally contains an extensive bibliography. (O. J. R. H.; W. E. Wh.)

Defence.—The early military history of Norway was one of storm and stress, marked by wars with Scandinavian neighbours and invasion of England up to the 11th century, of union with Denmark and Sweden (1389), separation (1523) and union with Sweden (1814) which endured until October 1905. Stable military conditions were established by a Treaty of Nov. 2, 1917, in agreement with Great Britain, France, Germany, Russia and Norway. From that date the Norwegian independent army on its present footing can be said to derive. Neutrality was maintained in the World War.

Recruiting Service and Organization.—All male Norwegians are liable to compulsory service, in the landsturm (only called up for defence in war) between the ages of 18 and 20, and 44 to 55; in the regular army for 12 years from the age of 20, with 72 to 126 days training in the first year and 24 days in 3 of the subsequent years; and in the territorial army from the ages of 32 to 44. The budget effective for 1928 numbered 4,325 regulars and district strength, 1,424 in the military schools, in addition to the annual contingent of about 15,000 under training.

See also *League of Nations Armaments Year-Book* (Geneva, 1928). (G. G. A.)

Navy.—The principal units are:—4 small coast defence battleships, 3 destroyers, 29 torpedo boats, 8 submarines, 9 miscellaneous vessels.

It is the intention (1928) to organise and modernise the fleet and to replace the older ships by those of a more modern type.

All seafaring men between the ages of 20 and 44 are liable for naval service. The Naval Air Service is gradually to be expanded to 96 hydroplanes. The navy and army are both administered by the Department of Defence. (E. A.)

ECONOMIC AND FINANCIAL CONDITIONS

The Pre-War Position.—For more than 30 years the economic life of Norway had developed on an increasingly industrial scale when the dissolution of the Union between Norway and Sweden, in 1905, gave it a fresh impetus. Very soon an extraordinary expansion set in, which continued practically undiminished up to the outbreak of the World War. The use of the waterfalls became an urgent question in politics.

Agriculture was, as it had been for centuries, the principal resource of the country by which, roundly, 890,000 persons gained their livelihood out of a population of two and one-third millions. The total number of farmers was 188,000, of which hardly one-tenth were tenants and leaseholders; the remainder freeholders. The chief cereals were oats, barley, rye and wheat, and the principal root crop potatoes. Cattle breeding was also developing on a satisfactory scale, and as an article of export of growing importance, condensed milk appeared in the statistics.

Next to agriculture, forestry is the most important trade of Norway, owing to the mighty industry which has grown up in connection with it. In 1913 about 85% of the forests were owned by private persons or companies, and 12½% by the State, while the remaining 2½% was owned jointly. From the latter half of the 16th to the latter half of the 19th century, sawn and planed timber constituted the chief articles of export derived from the

forest industry, but within the last 40 years prior to the war, the development of the mechanical and chemical wood-pulp industries as well as of the paper industry, had increased to an extent which made the timber industry lag far behind.

The mining industry, which in Norway dates from the beginning of the 17th century, experienced a renaissance, especially between 1897 and the outbreak of the war, owing to the increasing number of mines, mostly of iron ore, opened up in north Norway. From an annual output at the turn of the century valued at £260,000–270,000, the output expanded to a value of approximately £1,388,000 in 1913. A fishing fleet of steam vessels, larger sailing vessels supplied with auxiliary engines, and decked motor boats had to a great extent replaced the former old-fashioned fleet, while modern implements and methods had given the fisheries quite a new turn all round. As another important economic conquest within these years, allied to the fisheries, should be mentioned the whaling in the Antarctic, which, initiated in 1906, very soon proved a remarkable success. In 1913 the fisheries and the whaling yielded a profit of approximately £6,861,000 and £2,080,000, respectively. In connection with the fisheries should be mentioned the foundation of the canning industry which within the 30 years prior to the war became one of the most flourishing industries of Norway.

In 1900, the net register of steam and motor vessels was 498,447 tons. In 1914, it amounted to 1,223,009. Simultaneously, the net tonnage of sailing vessels decreased from 930,442 to 561,462; in fact only Great Britain, the United States and Germany had at the time larger mercantile fleets than Norway. About one-tenth of the fleet is engaged in regular trade along the coast of Norway, while another one-tenth is engaged in transport to and from foreign countries; the remainder have to seek employment in trade between foreign countries, which, in practice, means that the great bulk of Norwegian tonnage in pre-war days, as at present, was engaged in ordinary tramp trade all over the world.

Increased use of water-power has developed manufactures, for instance, the saltpetre industry, based on the principle of manufacturing nitrogen from the atmosphere, which was worked out in practice between 1906 and 1914. Owing to this extraordinary development in practically all fields, the trade balance of Norway also improved materially within the period, say from about £32,740,000 in 1906 to £52,994,000 in 1913.

Effects of World War Conditions.—These were, broadly speaking, the conditions of the leading trades of Norway when the outbreak of the World War suddenly upset the economic stability. But the nation soon adapted itself to the new state of things.

During the whole of 1915 the chief trades of the country achieved very considerable revenues. This especially applies to the shipping trade, and some of the leading manufacturing industries, while in other trades, e.g., the wood and the fishing trades, the deficiency as to quantitative returns were amply counter-balanced by the excellent prices obtained. During 1916 this development was even more pronounced. The revenues scored by shipping broke all previous records; the manufacturing industries were working under high pressure, while agriculture and the fisheries, although unsuccessful as to quantities, were remarkably profitable, owing to the unparalleled prices obtained for the products. At the same time the figures of the trade balance went up by leaps and bounds. Generally speaking, the closing months of 1916 mark the culmination of economic expansion during the war, and although extraordinary revenues were scored in the two following years, conditions were fraught with difficulties, owing to the more and more extraordinary character of the war by which Norway was affected, as perhaps no other neutral State, owing to her large mercantile fleet.

One of the first economic consequences of the war was, as already hinted at, the substantial rise in the international freight market in connection with a no less pronounced rise in the prices of all sorts of commodities and raw material, which quite naturally also brought about a constant rise in wages. During the first two years of the war the advantages derived from the enormous revenues more than counterbalanced these drawbacks, and

in a number of fields important results were achieved in the direction of consolidating the economic life on a national basis; on the other hand, the enormous influx of capital created exceedingly easy conditions in the money market, which very soon resulted in excessive speculation, chiefly in shipping and industrial shares, which threatened to become fatal. It should always be borne in mind that the losses inflicted upon Norway, chiefly through the German submarine war, were enormous—say 1,237,000 gross reg. tons—not to speak of the lives of nearly 2,000 seamen. After the war Norway had to rebuild a mercantile fleet of, roundly, 1.2 million gross reg. tons. This achievement, successfully performed within less than ten years after the war, under exceedingly difficult circumstances, will always rank among the most remarkable feats of Norwegian enterprise.

Post War Reaction.—Owing to a number of circumstances too intricate to be detailed, the economic reaction only became general towards the end of 1920, when the note circulation of the Bank of Norway reached an amount corresponding to £26,700,000, as compared with £6,000,000 in 1913, while, by an Order in Council of Aug. 1914 the bank had been exempted from redeeming its notes with gold. The increase of the loans of the private joint stock banks from, roundly, £35,555,000 at the outbreak of the war to £172,780,000 at the expiration of 1920, was another evidence of the inflation of the war period, along with the fact that the price index rose to 435 in the autumn of 1920 (1913 being 100). Yet it should not be forgotten that the item of deposits simultaneously rose from £32,900,000 to £172,888,000 while the deposits of the savings banks also increased heavily.

From the beginning of 1921 the reaction revealed itself in a way which makes that year a most gloomy one in the economic history of Norway. The fishing, mining and wood industries, her chief export industries, as well as shipping, suffered by the general collapse in the foreign markets, which led to a widespread cancelling of purchasing contracts. At the same time Norwegian money depreciated substantially, especially in relation to sterling and dollars, while the economic structure was severely shaken by an increasing number of banks being compelled to suspend payments. In addition to this may be mentioned the heavy increase in debts of the State and the municipalities.

Since 1924 an energetic work has been performed by patriotic forces in public and private life to restore the economy of Norway, and remarkable results have been achieved in a number of fields; among the most important should be mentioned that the kroner has again (May 1, 1928) been restored to the gold parity. At the same time the public debt is decidedly on the decline, while the industry is being reorganized by the foundation of an increasing number of new banks. (S. C. H.)

HISTORY

Archaeological and geological researches have revealed a fishing and hunting population in Norway, possibly as far back as c. 6000 B.C. Until lately this aboriginal people, which was certainly non-Aryan, was held to be Lappish, but recent investigations seem to show that the Lapps only entered Norway about A.D. 900–1000, and that the original population was probably of Finnish race, though only distantly allied to the Ugro-Finns now inhabiting Finland. To them belong perhaps certain non-Aryan names for features of the country, such as Toten, Vefsen, Bukn.

EARLY HISTORY

Teutonic Immigration.—The time of the immigration of a Teutonic element is uncertain. It did not extend N. beyond the Trondhjem district until about the beginning of our era, but the evidence of archaeology suggests that the Teutonic element entered S. Norway towards the end of the (Scandinavian) later Stone age, c. 1700 B.C. (see SCANDINAVIAN CIVILIZATION). The language of the older race was superseded by Teutonic, and those aborigines who were not incorporated (probably as slaves) were driven into the mountains or the islands that fringe the coast. In the highlands the “Finns” maintained some independence

down to historical times. The old English poem *Beowulf* mentions a “Finnland” which should perhaps be located in S. Norway in about the 6th century, and later on the ancient laws of this region forbid the practice of visiting the “Finns” to obtain knowledge of the future. But only in Finmark, which even in the 13th century stretched far into Sweden and included the Norwegian district of Tromsø, could the earlier inhabitants live their old life, and here they finally fell into the utmost want. Their existence is mentioned as a thing of the past by a North Trondhjem writer in 1689. The Teutonic element flowed into Norway from two centres; one western, probably from Jutland, the other eastern, from the W. coast of Sweden.

Early Kingship.—When history first sheds a faint light over Norway we find each small district or “fylke” (Old Norse *fylkir*, from *folk*, army) settled under its own king, and about twenty-nine *fylker* in the country. The king always possessed a *hird*, or company of warriors sworn to his service, and indeed royal birth and the possession of such a *hird*, and not land or subjects, were the essential attributes of a king. There was no law of primogeniture, and on the death of a king some of his heirs would take their share of the patrimony in valuables, gather a *hird*, and spend their lives in warlike expeditions (see VIKINGS), while one would settle down and become king of the fylke. There are indications that these conditions were fostered by a matriarchal system, and that it would often occur that a wandering king would marry the daughter of a fylke-king and become his heir. Probably the king's power was only absolute over his own *hird*. He was certainly commander-in-chief and perhaps chief priest of the fylke, but the administrative power was chiefly in the hands of the *herser* and possibly of an earl. The position of earls is vague, but it is noticeable that both those of whom we hear in Harald Haarfager's time take the opposite side to their king.

The eight Trondhjem *fylker* had a common *Thing* or assembly very early, but these districts were remote, while the wealthy western districts were too much cut off from each other to unite effectively, though here also a common *Thing* was early established. The first successful attempt at unification originated round Vestfold, the modern Jarlsberg and Laurvik Amt on the Christiania fjord, where it is possible that national feeling was fostered by proximity to the Danish and Swedish kingdoms. Tradition made the royal family a branch of the great Yngling dynasty of Uppsala, which claimed descent from the god Frey. Through several generations this family had extended its kingdom by marriage, conquest and inheritance, and by the end of the

BY COURTESY OF CANMERMEYERS FORLAG

NORWEGIAN HORSEMEN IN THE BRONZE AGE. FROM A ROCK CARVING IN BAAHUSLEN, FORMERLY SOUTHERN NORWAY

reign of Halfdan the Black, it included the greater part of Hamar and Oslo Stift, and the fylke of Sogn, the district round the modern Sognefjord.

Harald Haarfager.—Halfdan's son, Harald Haarfager, having no brothers, succeeded to the whole kingdom. By 866 his power was so well established in S. Norway that he contemplated the conquest of the whole land. There can be no doubt that Harald introduced a feudal view of obligations towards the king, and landowning families, who had regarded their *odel*, or inherited property, as absolutely their own, resented being forced to

pay dues on it. In each district Harald offered the *herse* the opportunity of becoming his vassals, answerable to him for the government of the district but many quitted the lands which were their real title to influence, rather than suffer the new order. Only the little kingdoms made futile attempts at combination, except in the western districts of Agde (comprising the modern Lister and Mandal and Nedenaes), Rogaland and Hordaland. Here was the home of the "western Vikings" who for nearly a century had owed wealth and fame to their raids on the British Isles. Attack by land was impossible, and Harald had to gather men and ships for three years before he could meet the fleet of the allied kings at Hafsford. The battle (872) resulted in a victory to him, and with it all opposition in Norway ended. An expedition to Scotland and the Scottish isles (c. 891) dispersed enemies who could harry the Norwegian coast, many of them taking refuge in Iceland; and the earldom of the Orkneys and Shetlands became an appanage of the Norwegian Crown. For the moment the whole country was under a single king, but Harald destroyed his work by giving about twenty of his sons the title of king, and dividing the country among them, only qualifying this retrograde step by installing his favourite son Erik Blodöxe as over-king (930). Moreover, Harald had established no common Thing for the whole of his kingdom, and the three natural divisions of the country remained more or less separate for centuries, even having separate laws until the second half of the 13th century.

The Successors of Harald.—Erik Blodöxe (Bloody-axe) only managed to rid himself of two rival over-kings, Olaf and Sigfred, his half-brothers, for on hearing of his father's death (933), another son, Haakon (*q.v.*), called the Good, who had been brought up at Aethelstan's court, came to Norway and succeeded in ejecting Erik (934). After Haakon's death in 961 at the battle of Fitje, where his long struggle against Erik's sons and their Danish allies terminated, these brothers, headed by Harald Graafeld (grey-cloak) became masters of the W. districts, though the ruling spirit appears to have been their mother Gunhild. Earl Sigurd of Lade ruled the N., and the S. was held by vassal kings whom Haakon had left undisturbed. By 969 the brothers had succeeded in ridding themselves of Sigurd and two other rivals, but the following year Harald Graafeld was lured to Denmark and treacherously killed at the instigation of Earl Haakon, son of Sigurd, who had allied himself with the Danish king Harald Gormssön. With the latter's support Earl Haakon won Norway, but threw off his yoke on defeating Ragnfred Erikssön at Tingenes in 972. The S.E. districts were, however, still held by Harald Grenske, whose father had been slain by the sons of Erik. Haakon ruled ably though tyrannically, and his prestige was greatly increased by his victory over the Jomsvikings, a band of pirates inhabiting the island of Wollin at the mouth of the Oder, who had collected a large fleet to attack Norway. The landed proprietors revolted and, in 995, there landed in Norway Olaf, great-grandson of Harald Haarfager and son of the king Tryggve of the Vik whom Gudröd Eriksson had slain, and whose father Olaf had been slain by Erik Blodöxe.

The earl was treacherously killed by his thrall while in hiding, and Olaf entered unopposed upon his short and brilliant reign. His great work was the enforced conversion to Christianity of Norway, Iceland and Greenland. Both Olaf and his successor and namesake looked for help to England, whence they obtained a bishop and priests; hence it comes that the organization of the early church in Norway resembles that of England. The hierarchical party in Norway only rose to power after the establishment of an archiepiscopal see at Trondhjem in 1152.

Relations with Denmark.—In the year 1000 Olaf fell at the battle of Svolder off Rügen, fighting against the combined Danish and Swedish fleets. The allies shared Norway between them, but the real power lay in the hands of Erik and Svein, sons of Earl Haakon. In 1015, when Erik was absent in England, another descendant of Harald Haarfager appeared, Olaf, the son of Harald Grenske, a great-grandson of Harald Haarfager (*see* OLAF II. HARALDSSÖN). He defeated Svein at Nesje in 1016, which left him free to work towards a united and Christian Norway,

but he strained the loyalty of his subjects too far, and on the appearance of Knut the Great in 1029 he fled to Russia. His death at the battle of Stiklestad on his return in 1030 was followed by a few years of Danish rule under Svein Knutssön, which rendered Olaf's memory sweet by contrast, and soon the name of St. Olaf came to stand for internal union and freedom from external oppression. In 1035 his young son Magnus, afterwards called the Good, was summoned from Russia, and was readily accepted as king. A treaty was made with Hardeknut which provided that whichever king survived should inherit the other's crown. Hardeknut died in 1042, and Magnus became king of Denmark, but a nephew of Knut the Great, Svein Estridsön, entered into league with Harald Haardraade (*see* HARALD III.), the half-brother of St. Olaf, who had just returned from the East. As soon, however, as overtures were made to him by Magnus, he forsook the cause of Svein, and in 1046 agreed to become joint king of Norway with Magnus. The difficulties arising out of this situation were solved by Magnus's death in 1047.

The End of Harald Haarfager's Line.—Harald's attempts to win Denmark were vain, and in 1066 he set about a yet more formidable task in attacking England, which ended with his death at Stamford Bridge in 1066. His son Olaf Kyrre (the Quiet) shared the kingdom with his brother Magnus until the latter's death in 1069, after which the country enjoyed a period of peace. In 1093 Olaf was succeeded by his turbulent son Magnus Barfod (barefoot) and by Haakon, son of Magnus the Good. The latter died in 1095. Besides engaging in an unsuccessful war against the Swedish king Inge, in which he was defeated at Foxerne in 1101, Magnus undertook three warlike expeditions to the Scottish isles. It was on the last of these expeditions, in 1103, that he met his death. He was succeeded by his three sons, Eystein, Sigurd and Olaf. Olaf died young. Sigurd undertook a pilgrimage, from which he gained the name of Jorsalfar (traveller to Jerusalem). He won much booty from the Moors in Spain, from pirates in the Mediterranean, and finally at Sidon, which he and his ally Baldwin I. of Jerusalem sacked. Eystein died in 1122. Sigurd lived till 1130, and was the last undoubted representative of Harald Haarfager's race, for on his death his son Magnus was ousted by Harald Gille, or Gilchrist, who professed to be a natural son of Magnus Barfod.

Disputed Successions.—Harald Gille was slain in 1136 by another pretender, and anarchy ruled during the reign of his sons Eystein, Inge and Sigurd Mund. At last Inge's party attacked and killed first Sigurd (1155) and then Eystein (1157). Inge fell in a fight against Sigurd's son Haakon Herdebreid in 1161, but a powerful baron, Erling, succeeded in getting his son Magnus made king, on the plea that the boy's maternal grandfather was King Sigurd Jorsalfar. In 1164 the archbishop of Trondhjem crowned Magnus, demanding that the crown should be held as a fief of the Norwegian Church. Owing to such concessions the Church was gaining a paramount position, when a new pretender appeared. Sverre (O.N. Sverrir) claimed to be the son of Sigurd Mund, and was adopted as leader by a party known as the Birkebeiner or Birchlegs. In spite of help from Denmark, the support of the Church and of the majority of barons, Magnus was defeated time after time, till he met his death at the battle of Nordnes in 1184. The aristocracy could offer little further opposition. In joining hands with the Church against Sverre, the local chiefs had got out of touch with the small landowners, with whose support Sverre was able to build up a powerful monarchy.

Magnus.—Sverre died in 1202. His son, Haakon III. died two years later, perhaps of poison, but the Birkebeiner party in 1217 succeeded in placing Haakon's son and namesake on the throne (*see* HAakon IV.). In 1240 the last of the rival claimants fell, and the country began to regain prosperity. The acquisition of Iceland was at length realized. Haakon's death occurred after the battle of Largs in 1263. The war with Scotland was soon terminated by his son Magnus, who surrendered the Hebrides and the Isle of Man at the treaty of Perth in 1268. He gained his title of Law-Mender from the revision of the laws, which until 1274 had remained very much as in heathen days. The new code repealed all the old werigild laws, and provided that the major

part of the fine for manslaughter should be paid to the victim's heir, the remainder to the king. Henceforward the council comes more and more to be composed of the king's court officials, instead of a gathering of the *lendermaend* or barons of the district in which the king happened to be. During Magnus's reign we hear of a larger council, occasionally called *palliment* (parliament), which is summoned at the king's wish. The old landed aristocracy had lost its power so completely that even after Magnus's death in 1280 it did not recover during the minority of his son Erik.

Paralysis of the Aristocracy.—Erik was succeeded in 1299 by his brother Haakon V., who in 1308 felt himself strong enough to abolish the dignity of the *lendermaend*. This paralysis of the aristocracy is no doubt partly to be ascribed to the civil wars, but in part also to the gradual impoverishment of the country, which told especially upon this class. Russia had long eclipsed Norway as the centre of the fur trade, and other industries must have suffered, not only from the civil wars, but also from the supremacy of the Hanseatic towns, which dominated the North, and could dictate their own terms. In earlier times the aristocratic families had owed their wealth to three main sources: commerce, Viking expeditions and slave labour. Trade had been a favourite means of enrichment among the aristocracy up to the middle of the 13th century, but now it was almost monopolized by Germans, and Viking enterprise was a thing of the past. The third source of wealth had also failed, for it is clear from the laws of Magnus that the class of thralls had practically disappeared. This must have greatly contributed to shatter the power of the class which had once been predominant.

Union of Norwegian, Swedish and Danish Thrones.—Haakon's daughter Ingeborg had married Duke Erik of Sweden, and on Haakon's death in 1319 their three-year-old son Magnus succeeded to the Norwegian and Swedish thrones, the two countries entering into a union which was not definitely broken till 1371. In 1343 Magnus handed over the greater part of Norway to his son Haakon VI., who married Margrete, daughter of King Valdemar III. of Denmark. Their young son Olaf V., already king of Denmark, succeeded to his father's throne on Haakon's death in 1380, but died in 1387, leaving the royal line extinct, and the nearest successor to the throne the hostile King Albrecht of Sweden, of the Mecklenburg family. The difficulty was met by filling the throne by election—an innovation in Norway, though it was the custom in Sweden and Denmark. The choice fell on King Haakon's widow Margrete, but a couple of years later, chiefly in order to gain German support in a coming struggle with the Mecklenburgers, the Norwegians elected as king the young Erik of Pomerania, great-nephew of the queen, who henceforth acted as regent. Erik had claims on the Swedish and Danish thrones, and in 1397, at Kalmar, he was solemnly crowned king over the three countries, which entered into a union "never to be dissolved."

Reigns of the Kings of Norway

Harald (I.) Haarfager	972-930	(d. 933)
Erik Blodøxe	930-934	
Haakon (I.) den Gode	935-961	
Harald (II.) Graafeld	961-970	
(Earl Haakon of Lade 970-995)		
Olaf (I.) Tryggvesson	995-1000	
(Earls Erik and Haakon 1000-1016)		
• Saint Olaf (II.)	1016-1029	(k. 1030)
Svein, son of Knut the Great	1030-1035	
Magnus (I.) den Gode	1035-1047	
Harald (III.) Haardraade	1047-1066	
Olaf (III.) Kyrre	1066-1093	
Magnus (II.)	1066-1069	
Magnus (III.) Barfod	1093-1103	
Eystein (I.)	1103-1122	
Sigurd (I.) Jorsalfar	1103-1130	
Olaf (IV.)	1103-1116	
Magnus (IV.)	1130-1135	
Harald Gille	1130-1136	
Sigurd (II.) Mund	1136-1155	
Eystein (II.)	1136-1157	
Inge	1136-1161	
Haakon (II.) Herdebrød	1161-1162	
Magnus (V.)	1162-1184	
Sverre	1184-1202	

Haakon (III.)	1202-1204
Haakon (IV.) den gamle	1217-1263
Magnus (VI.)	1263-1280
Erik	1280-1299
Haakon (V.)	1299-1319
Magnus (VII.)	1319-1343
Haakon (VI.)	1343-1380
Olaf (V.)	1381-1387
Margrete	1387-1389
Erik of Pomerania	1389-

Bremer, K. Kaalund and V. Gudmundsson in *Pauls Grundriss der germanischen Philologie* (vol. iii., Strassburg, 1900). The above works are published in Christiania except where otherwise stated. In English, there is a history of Norway by H. H. Boyesen in the *Story of the Nations* series (1900), and K. Gjerset's *Hist. of the Norwegian People*, 2 vols. (1915) and also historical notes in G. Vigfusson and F. Y. Powell's *Corpus poeticon Boreale* (Oxford, 1883). The most important original sources are: Snorre Sturlasson's *Heimskringla*, or Lives of the Kings of Norway up to 1177, of which there are Eng. trans. by W. Morris and E. Magnusson, with a valuable index volume in the *Saga Library*, vols. iii.-vi., (1893-1905) and in the *Everyman Library* (1915). The original Icelandic text is edited by F. Jónsson (Copenhagen, 1893-1901). For a critical investigation into the sources of Snorri and the contemporary historians, see G. Storm, *Snorre Sturlasson's Historiekrivning* (Copenhagen, 1873, with map of ancient Norway), and F. Jónsson, *Den oldnorske og oldislandske Litteraturs Historie* (Bd. ii. Del. ii., Copenhagen, 1901). Of later sagas, Sverre's Saga (*Fornmanna Sögur*, vol. viii., Copenhagen) is translated by J. Sephton, *Northern Library* (vol. iv., 1899), and *Haakon's Saga* is given with a translation by G. W. Dasent in vols. ii. (text) and iv. (translation) of the *Chronicles and Memorials of Great Britain and Ireland* (London, 1894). Other important sources are: *Diplomatarium Norvegicum*, ed. C. Unger, Christiania, and *Norges Gamle Love indtil 1397*, ed. R. Keyser and P. A. Munch (5 vols., Christiania, 1846-95). (B. S. P.)

1397-1814

The history of Norway from 1397 down to the union with Sweden in 1814 falls naturally into four divisions. First, in 1450, the triple bond gave place to a union in which Norway became more firmly joined to Denmark. Next, in 1536, as the result of the Reformation, Norway sank almost to the level of a province. After 1660 she gained something in status from the establishment of autocracy in Denmark, and in 1814 she became a constitutional kingdom on a footing of approximate equality with Sweden. But for the convulsions to which some of these changes gave rise, Norway possesses during this period but little history of her own, and she sank from her former position as a considerable and independent nation. The kings dwelt outside her borders, her fleet and army decayed, and her language gradually gave place to Danish. Germans plundered her coasts and monopolized her commerce, and after 1450 Danes began to appropriate the higher posts in her administration. When in 1448 Karl Knutsson was chosen king by the Swedes, and Christian of Oldenburg by the Danes, it was by force that Norway fell to the latter. The Norwegians protested, but the next year the Swedes assented to a separation. Christian I. (1450-81) gave estates and offices in Norway to his Danish subjects and raised money by pawning her ancient possessions, the Orkneys and Shetland islands, to the king of Scotland. His son Hans (1482-1513) purchased the obedience of the Norwegian nobles by concessions to their power. The imposing union continued in name, but the weakness of the nation and its government was strikingly illustrated when the Germans in Bergen besieged a monastery in which a high official had taken refuge.

After the downfall of Christian II. (1513-24) the position of Norway was changed for the worse. She was ruled for a century and a quarter by Danish officials; her churches and monasteries were sacked by Danes, and Danes were installed as pastors under the Lutheran system, which the Norwegians were compelled to accept in 1539. Soon Norway was dragged by Denmark into the

so-called Seven Years' War of the North (1563-70). However, the power of the Hanse League in Bergen was broken. The rule of the Oldenburg dynasty proved neglectful rather than tyrannical, and under it the mass of the peasants was not flagrantly oppressed. Christian IV. (1588-1648), who founded Christiania (Oslo), may almost be said to have discovered Norway anew. He reformed its government and strove to develop its resources, but his policy involved the loss of Jemtland and Herjedalen, which were ceded to the Swedes by the peace of Brömsebro (1645). The Danish war of revenge against Charles X. of Sweden resulted in further loss by Norway. By the peace of Roskilde (1658) she was compelled to renounce Trondhjem and Baahus, and although the former was restored by the peace of Copenhagen, (1660), her population fell below half a million. The Swedes had now acquired the rich provinces in the south and south-west of the Scandinavian peninsula, and their ambition to extend their frontiers to the North sea grew. From the middle of the 17th century, however, the Dutch and English made their influence felt, and the political status of Norway could no longer be regarded as a purely Scandinavian affair. The establishment of hereditary autocracy in Denmark by Frederick III. in 1660 conferred many benefits upon Norway. The Norwegian peasant remained a freeman while his counterpart in Denmark was a serf. Norwegian law was revised and codified under Christian V. (1670-99), who was well served by the Norwegians in his attempt to regain the lost provinces from Charles XI.

Under the sons of these monarchs, Frederick IV. and Charles XII., Norway was once more compelled to pay for Danish aggression. Her shipping was destroyed, and in 1716, when driven from continental Europe, Charles XII. fell upon her. Only his death, in 1718, averted the danger. During this war Peter Tordenskjold, the greatest among a long series of Norwegian heroes who served in the Danish fleet, won undying fame. Before the close of the 18th century something had been done towards dispelling the intellectual darkness. Holberg, though he flourished outside Norway, by stemming the tide of German influence made the future of Norwegian literature possible. At the close of the century Hauge, the Wesley of Norway, appeared, while the growth of the timber trade with England gave rise to a great increase in wealth and population. In a century and a half the number of the Norwegian people was doubled, so that by 1814 the population was 900,000. In 1788 the oppressive law that grain should be imported into Norway only from Denmark was repealed, and thanks to Danish policy, Norway actually drew financial profit from the wars of the French Revolution.

The Norwegian national movement was to render a decade at the beginning of the 19th century more memorable in Norwegian history than any century which had passed since the Calmar Union. In 1800 the Danish Government committed the Norwegians to the second Armed Neutrality, and therefore to a share in the battle of Copenhagen, by which it was broken up. It was not until 1807, however, that Norway was fully involved in the Napoleonic wars. Then, after the bombardment of Copenhagen, she was compelled by Danish policy to embrace the cause of Napoleon against both England and Sweden. Commerce was annihilated, and the supply of food failed. The national distress brought into the forefront of politics national leaders, among whom Count Wedel-Jarlsberg was the most conspicuous. As yet, however, patriotism went no farther than a demand for a national administration and university; concessions which were accorded by Denmark in 1807 and 1811.

UNION WITH SWEDEN

Three years later the nascent nation found itself suddenly transferred to the rule of the king of Sweden. The Swedes, with Bernadotte as the heir-apparent, had fought against Napoleon, while the Danes, under Frederick VI., had espoused his cause. The result was the treaty of Kiel (Jan. 14, 1814), which, as was generally understood, compensated Sweden for her loss of Finland to Russia by giving her Norway. But the Norwegians, who had not been consulted in the matter, declared that, while the Danish king might renounce his right to their crown, it was

contrary to international law to dispose of an entire kingdom without the consent of its people. A meeting was convened at Eidsvold, where, on May 17, 1814, a constitution, framed upon the constitutions of America, of France (1791), and of Spain (1812), was adopted. It made the *storting*, or National Assembly, a single-chamber institution, and gave the king no absolute veto, or right of dissolution. The Danish governor of Norway, Prince Christian Frederick, was unanimously elected king. Bernadotte invaded Norway, but after a fortnight opened negotiations. A convention at Moss proposed that the Norwegians should accept the Swedish king as their sovereign, but that the Eidsvold constitution should remain. An extraordinary *storting* at Christiania, on Nov. 4, 1814, declared Norway "a free, independent, and indivisible kingdom, united with Sweden under one king." Prince Christian Frederick had already left the country.

The Act of Union.—The Act of Union, which was accepted by both countries in the following year, stated that the union was accomplished "not by force of arms, but by free conviction," and the Swedish foreign minister declared to the European Powers that the Treaty of Kiel had been abandoned, and that the union was due to the confidence of the Norwegians in the Swedish people. The Eidsvold constitution henceforward formed the *Grundlov*, or fundamental law. The union thus concluded was really an offensive and defensive alliance under a common king, each country retaining its own government, parliament, army, navy and customs. The Swedish people, none the less, believed that they had won Norway by arms. As the national principle grew more powerful, and the Norwegians richer, more numerous and more self-conscious, a tension developed on the question of union which was eased only by severance in 1905.

From 1814 to 1829 the king was represented by a Swedish viceroy, while the government was, of course, composed only of Norwegians. Count Wedel-Jarlsberg was its first head while several of Prince Christian Frederick's councillors of state were retained. Over the first two viceroys Count Wedel exercised considerable influence.

The end of the Napoleonic wars brought to Norway poverty and depression of trade, and her finances were in a deplorable condition. The *storting* therefore cut down the army by one-half and founded a bank of Norway. The paid-up capital was procured by an extraordinary tax, and this, together with the growing discontent among the peasantry, brought about a rising in Hedemarken, designed to dissolve the *storting* and to reduce taxation. The rising, however, soon subsided, and the bountiful harvest of 1819 brought more prosperous times. Meanwhile, however, the financial position had endangered independence. The settlement with Denmark of Norway's share of their joint national debt threatened to provoke the intervention of the Powers. Bernadotte, now Charles XIV. of Sweden (Feb. 5, 1818), accepted England's mediation, and in Sept. 1819 concluded a convention with Denmark, by which Norway was held liable for only 3,000,000 specie dollars (nearly £700,000). The obstinacy of the *storting* in 1821, however, nearly occasioned a fresh interference of the Powers. When at last the Norwegians yielded, the king doubted their sincerity, and in July 1821 assembled 3,000 Swedish and 3,000 Norwegian troops near Christiania (Oslo), ostensibly for manoeuvres. A circular note (June 1) to the Powers complained bitterly of his treatment by the *storting* and courted their sympathy for any attempt to revise the Norwegian constitution. The *storings* of 1815 and 1818, moreover, had passed a bill for the abolition of nobility, which the king had refused to sanction. The Norwegians maintained that the few remaining counts and barons were all Danish and of very recent origin, while the true nobility of the country were the peasants, descendants of the old jarls and chieftains. According to the constitution, any bill passed by three successive *storings*, elections being held every third year, became law without the king's sanction, and, though the king did everything to obstruct it, the bill was carried.

In 1822 Count Wedel-Jarlsberg retired. In 1821 he had been impeached before the Rigsret, the supreme court of the realm, for having caused the state considerable losses. Jonas Collett (1772-1851) succeeded as minister of finance. The king,

apparently abandoning his plans for a *coup d'état*, now substituted proposals for removing from the constitution all that was at variance with a monarchical form of government. These changes had been suggested in his circular note to the Powers, and were designed to please his Swedish subjects. In 1824 and subsequently, however, the *storting* unanimously rejected not only the king's proposals, but also others by private members. In 1830 they were discussed for the last time, with the same result. The *storting* thus became regarded as the defender of the constitution against a would-be absolutist king, while the king began to consider the celebration of May 17 (Independence day) as a demonstration against himself, and when Collett was impeached for having made payments without the sanction of the *storting*, he regarded it as an attack upon his royal prerogatives. Although Collett was acquitted, he dissolved the *storting* with every sign of displeasure. The Swedish viceroy tried to convince him that his prejudice against the celebration of May 17 was groundless, but in 1827 it was celebrated in a very marked manner, and was followed by a demonstration against *The Union*, a foolish political play. The king therefore appointed Count Platen, whose first act was a proclamation against celebrating the day of independence. In April 1828 the king, against the advice of his ministers, summoned an extraordinary *storting*, to recover the supremacy lost to the *storting* in 1827. He also intended to prevent the celebration of May 17, and assembled 2,000 Norwegian soldiers near the capital. Though present in person, he did not accomplish any constitutional changes, but the *storting* decided to omit the celebration, and the people quietly acquiesced. In the following year, however, trouble broke out again. Crowds paraded the streets, singing and shouting, and gathered finally in the market-place. A little rioting, and its suppression with sword and musket, became known as the "battle of the market-place," and did much to increase the ill-feeling against Count Platen. He died in Christiania (Oslo), at the end of the year, and his post remained vacant for several years.

Development of the National Movement.—The July revolutions of 1830 stimulated political consciousness in Norway at a time when the peasants in the *storting* were challenging the representatives of the official classes, hitherto supreme. This party was ably led by Ole Ueland, a member of every *storting* from 1833 to 1860. The *storting* of 1833 was the first of the so-called "peasant *stortings*," their numbers rising from 20 or less to 45, nearly half of the total representation. They found a champion in the youthful poet Henrik Wergeland, who soon became one of the leaders of the "Young Norway" party. He was a republican in politics, and the most zealous upholder of the national independence of Norway and of her full equality with Sweden. Another rising poet, J. S. Welhaven, led the upper classes against Wergeland and the peasants, who sought to make the cultural separation from Denmark as complete as possible, and in every way to encourage national feeling among the people. Though zealous for the education of the people and beloved by the poorer classes, Welhaven could form no political party and at his death in 1845 stood almost isolated. His opponents then became the leaders in the field of literature, and carried on the work of national reconstruction with more restraint.

While the violent agitation of 1830 died away, the tension between king and *storting* reached its height during the session of 1836, when all the royal proposals for changes in the constitution were laid aside, without even passing through a committee. The king decided to dissolve; but Lövenskiöld, one of the ministers, was impeached for this decision, and eventually fined 10,000 kroner (about £550), though retaining his post. Collett, who had greatly displeased the king, was dismissed; but unity in the government was brought about by the appointment of Count Wedel-Jarlsberg as viceroy. From this time the relations between the king and the Norwegian people began to improve, whereas in Sweden he was, in his later years, not a little disliked.

When the king's anger had subsided, he summoned an extraordinary session, in which the *storting* urged that steps should be taken to place Norway upon an equal footing with Sweden, especially in the conduct of diplomatic affairs. The same address con-

tained a petition for the use of the national or merchant flag in all waters. The constitution gave Norway her own merchant flag, and in 1821 the *storting* had resolved that this should be scarlet, divided into four by a blue cross with white borders. The king gave permission only for its use in waters near home. Beyond Cape Finisterre the naval flag, which was really the Swedish flag, with a white cross on a red ground in the upper square, must be borne. Royal permission in 1838 for all merchant ships to carry the Norwegian flag in all waters was hailed with great rejoicings; but the question of the national flag for general use had yet to be settled, and in 1839 the king appointed a committee of four Norwegians and four Swedes, to consider the question raised about diplomacy and the equality of Norway in the union.

Its powers were extended to consider a comprehensive revision of the Act of Union, with the limitation that fundamental conditions must in no way be interfered with. But before the committee had finished their report the king died (March 8, 1844), and was succeeded by his son Oscar I. According to the constitution the Norwegian kings must be crowned in Trondhjem cathedral, but as the bishop doubted whether the queen, a Roman Catholic, could be crowned, the king decided to forgo coronation. He soon showed his desire to meet the wishes of the Norwegian people, decreeing that in all documents concerning her internal government Norway was to stand first in the royal title; that Norway and Sweden should each carry its own national flag as the naval flag, with the mark of union in the upper corner; and that the merchant flag should bear the same mark of union.

The condition of the country had now considerably improved, and King Oscar's reign was marked by the carrying out of important legislative work and reforms. New roads were made, the first railway built, steamship routes established, lighthouses erected, and trade and shipping developed. During the Schleswig-Holstein rebellion (1848-50) and the Crimean War, Norway and Sweden remained neutral and Norwegian shipping especially benefited. The abolition of the English navigation acts in 1850 opened up a great future for the Norwegian merchant fleet.

In 1826, by the treaty with Russia, the frontier in the Polar region was definitely delimited; but in 1851 Russia demanded for her frontier Lapps the right to fish on the Norwegian coast, and to settle upon a portion of the coast on the Varanger fjord. The Norwegian Government refused, and serious complications might have ensued if the attention of Russia had not been turned in another direction. During the Crimean War the king concluded a treaty with England and France by which these countries guaranteed Norwegian and Swedish territory against Russia. Relations with Russia therefore became strained; but after the peace of Paris in 1856, and the accession of Alexander II., the Russian ambassador at Stockholm restored harmony.

Owing to the king's ill-health his son was appointed regent in 1857, and two years later succeeded as Charles XV. This gifted, genial and noble king desired to inaugurate his reign by proof of his willingness to acknowledge the claims of Norway, but he did not live to see his wishes carried out. According to the constitution, the viceroy might be either a Norwegian or Swede. Since 1820 no Swede had held the post, and since 1850 no appointment had been made. But the paragraph in the constitution still existed, and the Norwegians naturally wished to have this stamp of "provinciality" obliterated. A proposal to abolish the office was passed by the *storting* in 1859. The king had privately promised that he would sanction the proposed change in the constitution; but a violent outcry arose in Sweden. Under pressure the king eventually refused to sanction the resolution; but he added that he shared the views of his Norwegian counsellors, and would, when "convenient," himself propose the abolition.

In the following year the Swedish Government pressed the demands of the Swedish Estates for a common parliament which, according to population, would contain two Swedish members to every Norwegian. The Norwegian Government did not seem at all disposed to entertain the proposal; but some dissensions arose with regard to the form of its reply. The more obstinate members of the ministry resigned, and others, of a more pliable nature, were appointed under the presidency of Fredrik Stang, min-

ister of the interior from 1845 to 1856. Both the new and old governments agreed that no proposal for the revision of the Act of Union could then be entertained. The king, however, advocated a revision based upon full equality. In 1863 the *storting* assented to his appointment of a second Union committee. It was not until 1867 that its report was made public, and it could not be discussed by the *storting* before 1871. Meanwhile, the Danish complications in 1863-64 threatened to draw the two kingdoms into war. The king favoured a defensive alliance with Denmark, but the *storting* would only consent if an alliance could also be effected with at least one of the Western Powers.

In 1869 the *storting* passed a resolution by which its sessions were made annual instead of triennial. The first yearly *storting* in 1871 had once more to consider revision. The Norwegians steadily postulated (1) the full equality of the two kingdoms, and (2) no extension of the bonds of the union. However, the new draft implied the supremacy of Sweden and introduced important extensions of the bonds of the union. Strangely enough, the new Stang ministry accepted it and it was even supported by some of the most influential newspapers under the plausible garb of "Scandinavianism." In these circumstances the "Lawyers' Party," under the leadership of Johan Sverdrup, and the "Peasant Party," led by Søren Jaabæk, allied to defend the constitution of 1814. Thus was founded the great national party of the "Venstre" (the left). The proposed revision in 1871 was rejected by an overwhelming majority.

In 1872 a private bill proposed that ministers should be admitted to the *storting* and take part in its proceedings. After stormy debates, Sverdrup carried the bill by a large majority, but the Government, jealous of the new Liberal Party, advised the king to refuse his sanction. In the preceding half-century the Government Party had several times introduced a similar bill, but the opposition had feared lest the superior skill in debate and political experience of the ministers should turn the scale too readily in favour of Government measures. Now, on the contrary, the opposition had gained more experience and had confidence in its own strength; but the Government saw in the proposed reform the introduction of full parliamentary government, by which they could not remain in office unless supported by a majority. The Liberals carried a vote of censure against the Government but the king declared that the ministers enjoyed his confidence. Three, however, resigned, and enthusiastic public meetings were held all over the country in support of the proposed reform.

In Sept. 1872, Charles XV. was succeeded by his brother, Oscar II. In the following year the king sanctioned the abolition of the office of viceroy, and the president of the ministry was afterwards recognized as the prime minister. Stang was the first to fill this office. In the same year Norway celebrated its millenary with great festivities.

Struggle Between the King and the Storting.—In 1874 the government, in order to show the people their goodwill, laid before the *storting* a royal proposition for the admittance of the ministers to the national assembly. But this was to be accompanied by certain other constitutional changes, such as the royal right of dissolving the *storting*, and providing fixed pensions for ex-ministers, as a guarantee against the majority misusing its new power. The bill was unanimously rejected by the *storting*, who in the same year, and again in 1877, passed a modified version of the bill of 1872. On both occasions the king refused his sanction. The *storting* accordingly resorted to the procedure provided by the constitution to carry out the people's will. In 1880 the bill was passed for the third time, by 93 votes out of 113. To the general surprise, the king again refused his sanction, declaring that his right to the absolute veto was "above all doubt." Sverdrup, the Liberal leader and president of the *storting*, therefore proposed that the bill, which had been passed three times, should be declared to be the law of the land. This was carried by a large majority on June 9, 1880, but the king and his ministers declared the resolution invalid. The faculty of law at the Christiania (Oslo) university with one dissentient upheld the king's right to the absolute veto in questions concerning amendments of the constitution, although they could not find that it was expressly stated

in the fundamental law of the country. The ministry also advised the king to claim a veto in questions of supply, which still further increased the ill-feeling in the country against them.

The prime minister, Stang, now resigned, and C. A. Selmer (1816-89) became his successor—an appointment which indicated that the conflict was to be continued. In June 1882 the king came to dissolve the *storting*, and astonished the people by censuring their representatives in a speech from the throne. Sverdrup and Bjørnstjerne Bjørnson, the popular poet and dramatist, called upon the people to support the *storting* in upholding the resolution of June 9. In the elections the Liberals won 83 seats to the Conservatives' 31. The ministry, however, showed no sign of yielding, and, when the new *storting* met in Feb. 1883, the Odelsting (the lower division of the national assembly) decided to impeach the whole of the ministry. They were charged with having acted contrary to the interests of the country by advising the king to refuse his sanction—first, to the amendment of the law for admitting the ministers to the *storting*; secondly, to a bill involving supply; and thirdly, to a bill by which the *storting* could appoint additional directors on the state railways.

After ten months' trial, the Rigsret sentenced Selmer and seven of his ministers to be deprived of their offices; while three, who had either recommended the king to sanction the bill for admitting the ministers to the *storting*, or had entered the cabinet at a later date, were heavily fined. The excitement in the country rose to fever-height. It was generally believed that the king would attempt a *coup d'état*. Fortunately, after some hesitation, he issued (March 11, 1884) an order in council announcing that the judgment would be carried into effect. King Oscar, however, in his declaration upheld the constitutional prerogative of the crown, and in April asked Schweigaard, one of the ministers who had been fined, to form a ministry. His "April ministry" sent in its resignation in the following month; a similar nomination failed, and the king was at last compelled to appoint Sverdrup. Thus the first Liberal ministry in Norway came into being (1884). The *storting*, to satisfy the king, passed a new resolution admitting ministers, and this received formal sanction.

During the following years a series of important reforms was carried through. In 1887 the jury system in criminal matters was introduced after violent opposition from the Conservatives. A bill intended to give parishioners greater influence in church matters, however, was eventually rejected, the result being a break-up of the ministry and a disorganization of the Liberal Party. In June 1889 Sverdrup resigned, and a Conservative ministry was formed by Emil Stang. After two fruitful years this was wrecked on the diplomatic question. In 1814 nothing had been settled about the conduct of diplomatic affairs; in 1835 a resolution was issued which in effect gave Norway a right of inspection of business transacted on her behalf by the Swedish foreign minister with the king. The Swedes were willing to grant equal representation in a joint council, but on the assumption that the minister of foreign affairs should continue to be a Swede, and this the Norwegians would not accept. In 1891, after a deadlock, the Stang ministry resigned, and a Liberal ministry under Sverdrup's successor, Steen, was appointed.

A new deadlock was produced by the resolve of the *storting* in 1892 to establish a separate consular service for Norway, which provoked the king's veto and the resignation of the ministry. By a compromise, the ministry returned to office, on the understanding that the question was postponed. In 1893 the *storting* again passed a resolution for the establishment of the proposed consular service, but the king again refused his sanction. Upon this the Liberal ministry resigned (May 1893), and the king appointed a Conservative Government, with Stang as its chief. At the end of 1894, when the triennial elections took place, the majority declared in favour of national independence on the great question then before the country. In 1895, after over four months without a responsible Government, a coalition ministry was formed, with Professor G. F. Hagerup as prime minister. A new committee of Norwegians and Swedes spent over two years in fruitless labour on the question of separate diplomatic representation. At the elections in 1897, 79 Liberals and 35 Conservatives were

returned, and in Feb. 1898 Hagerup was replaced by Steen. Soon afterwards the bill for the general adoption of the national or "pure" flag was carried for the third time, and became law without the king's sanction. In 1898 universal political suffrage for men was passed by a large majority, but the proposal to include women received only 33 votes.

NORWAY INDEPENDENT

The Consular Crisis.—In Jan. 1902, on the initiative of the Swedish foreign minister, another joint committee on the consular question was appointed. It unanimously reported that "it was possible to appoint separate Norwegian consuls exclusively responsible to Norwegian authority and separate Swedish consuls exclusively responsible to Swedish authority." Further negotiations resulted in the so-called *communiqué* of March 24, 1903, which announced an agreement between the two countries for a separate consular service. In due course the Norwegian Government submitted to the Swedish Government their draft of the proposed laws and regulations, but no reply was forthcoming for several months. The friendly Swedish foreign minister, Mr. Lagerheim, resigned, and in Nov. 1904 Boström, the prime minister, suddenly submitted to the Norwegian Government a number of new conditions for the establishment of separate consuls. According to Boström's proposals, the Norwegian consuls were to be placed under the control of the Swedish foreign minister, who was to have the power to remove them. Hagerup proceeded to Stockholm, but no satisfactory agreement could be arrived at. The Norwegians felt that nothing remained but to take matters into their own hands. On March 1, 1905, Hagerup resigned and was succeeded by Christian Michelsen, and a ministry from both political parties. A bill was resolved on for the establishment of a Norwegian consular service not later than April 1, 1906. During the king's illness the crown prince vainly attempted to reopen negotiations. In April Boström resigned, apparently to facilitate negotiations. On May 23 the bill was passed by the *storting* without a dissentient voice, but on May 27, in spite of the earnest entreaties of his Norwegian ministers, the king refused his sanction. The Norwegian Ministry immediately resigned, but the king would not accept their resignation, which they declined to withdraw. On June 7, Michelson informed the *storting* that, as an alternative Government could not be formed, the union with Sweden, based upon a king in common, was dissolved. The resigning ministry was unanimously authorized to exercise the authority vested in the king in accordance with the constitution.

Separation from Sweden.—On receiving this news, the king sent a telegraphic protest to the Norwegian prime minister and to the president of the *storting*, and the Swedish Government summoned an extraordinary session of the Riksdag (parliament) for June 20, when a special committee was appointed to consider the crisis. On July 25 it reported to the Riksdag that Sweden could have no objection to enter into negotiations about the severance of the union, when a vote to the effect had been given by a newly elected *storting* or by way of referendum. The report was unanimously adopted on July 27, and the next day the *storting* decided that a general plebiscite should be taken. On August 13, 368,211 voted for the dissolution and only 184 against it. It was thereupon agreed that representatives of Norway and of Sweden should meet to arrange for the severance of the union. After more than three weeks of difficult negotiation, agreement was reached on Sept. 23. This provided for a neutral zone on both sides of the southern frontier, the Norwegians undertaking to dismantle some fortifications within that zone. The agreement was to remain in force for ten years, and could be renewed for a similar period, unless one of the countries gave notice to the contrary. On Oct. 27, after ratification by *storting* and Riksdag, the king relinquished the crown of Norway. Failing acceptance by a member of the house of Bernadotte, it was conferred upon Prince Charles of Denmark by a second popular vote (259,563 against 69,264) and by the *storting* with no dissentients. On Nov. 25, the king, now Haakon VII., and Queen Maud, the youngest daughter of Edward VII. of England, entered the Norwegian capital.

In 1907 parliamentary suffrage was granted to women with the

same limitation as in the municipal suffrage granted to them in 1901, viz., to all unmarried women over 25 years, who pay taxes on an income of 300 kroner (about £16) in the country districts and on 400 kroner (about £22) in the towns, as well as to all married women whose husbands pay taxes on similar incomes. Norway was thus the first sovereign country in Europe where women gained the vote.

1907-1914.—The Michelsen Government, which achieved these results, functioned in a *storting* composed of some 77 Liberals and parties of the Left, 36 Conservatives, and 10 members of the new Labour Party. In Oct. 1907 the premier was succeeded by his minister of foreign affairs, R. J. Läländ. Most of the Left then reorganized as the Consolidated Left under Gunnar Knudsen, who became premier in March 1908. Knudsen's administration carried through the "concession laws," making it impossible to buy waterfalls of more than 1,000 h.p., forests, mines and other real property without a concession from the Government.

The Conservative Parties opposed especially the proviso that concessions should not be granted for more than 60 years, and that on their expiration all waterfalls, power stations, etc., should become national property without compensation. In March 1909 a group of the old Liberals reorganized as the Liberal Left. In the general elections of Oct. 1909 the Conservatives and Liberals secured 63 seats, as against 47 Radicals, 11 Socialists and two Independents, and on Feb. 1, 1910, formed a Coalition Government under the old Liberal leader Wollert Konow. In 1911 the Government passed a new taxation law introducing compulsory declaration of income and limiting rights of municipal taxation. Owing to persistent friction on the *landsmål* question (see NORWEGIAN LITERATURE), Konow resigned (Feb. 1912), and was succeeded by the Conservative leader Bratlie. But this friction had weakened the coalition; the elections of 1912 returned 76 Radicals against 24 Conservatives and Liberals and 23 Socialists. Knudsen again became premier, with Castberg the leading member of his cabinet. Controversy centred round the so-called "Castberg laws," giving illegitimate children equal rights of inheritance with legitimate, except in the case of peasants' farms, and imposing on the fathers increased obligations to protect their illegitimate children and the mothers of them. The laws were passed in 1915 by the Radical majority, after Castberg had left the cabinet. In 1914 the centenary of the Norwegian constitution was celebrated.

1914-1920.—A controversy with Sweden concerning the suzerainty over a group of submarine skerries, Grisebaaerne, was decided by The Hague Tribunal in 1908. The World War brought the three Scandinavian countries closer together. In Aug. 1914 they proclaimed strict neutrality and signed an agreement to remove any possibility of either country preparing hostile action against the other. On Dec. 18-19 the three Scandinavian kings with their premiers and foreign ministers met in Malmö to discuss joint action regarding questions raised by the war. Similar conferences of the Scandinavian premiers and foreign ministers were held in Copenhagen (March 1916), in Oslo (Sept. 1916), in Stockholm (May 1917), Copenhagen (June 1918), Stockholm (May 1919), Oslo (Feb. 1920) and in Copenhagen (Aug. 1920).

After the first panic at the outbreak of war, both public and private enterprises made vast profits and incurred extravagant expenditure. Wages and salaries rose rapidly; the shipping companies paid huge dividends; all sorts of new financial and industrial enterprises were started; imports reached an enormous height. The elections of 1915 returned the previous Government with an increased majority; 80 Radicals were elected, 20 Conservatives, 19 Socialists and 4 Independents. The Government received extraordinary powers. A vitualling commission controlled prices and imports, and a price directorate controlled retail prices. In 1916 grains and cereals, meat, sugar, coffee and tea were rationed. Temporary Prohibition was initiated in Dec. 1916, and extended in June 1917 to all trade in wines of an alcoholic strength of over 12%. In July 1916, as the result of a violent struggle in the labour market, an emergency measure was passed—under protests from both Labourites and Conservatives—prohibiting strikes and lock-outs and enforcing public arbitration in industrial conflicts. In spite of extraordinary revenues, however,

the national debt, thanks to the needs of defence and bonuses to officials, rose from 362,300,000 kroner in 1914 to 736,600,000 kroner in 1917 and 1,008 million at the end of 1918.

The new elections in the autumn of 1918 brought a strong reaction. The Radicals lost 26 seats, the Socialists lost one, the Conservative-Liberals gained 30. These elections threw into relief the unfair electoral system, which had hitherto secured the Left a number of seats out of all proportion to the votes cast for them. The Conservatives, assisted by Labour—where the moderates were losing power in consequence of the impossibility of achieving results by parliamentary methods—were now able to establish proportional representation. The Knudsen cabinet tendered its resignation in Jan. 1919, but as the Conservatives had no working majority it continued to sit till June 1920, when Otto Halvorsen, the Conservative leader, succeeded Knudsen.

1920-1927.—Halvorsen's cabinet was immediately faced with the most formidable labour troubles. After 1906 more Socialists had entered the *storting* and gained rapidly in influence. They collaborated closely with the trade unions which in 1889 had been merged into a national federation under a central committee, elected partly by the trade unions, partly by the Labour Party. The trade unions were similarly represented in the executive committee of the Labour Party. Under the influence of the Russian revolution of 1917, the Radicals gained the upper hand at the party congress and in the executive committee in 1918; in 1919 the Norwegian Labour Party joined the Third International, and sent a member to the executive committee in Moscow. The moderate leaders then left the Labour Party and founded the Social Democratic Party.

A wave of revolutionary feeling spread over Norway, the fruits of which were the "revolutionary" railway strike of Dec. 1920 and the national strike of May 1921. The cabinet met both strikes successfully; the railwaymen (who were State employees) capitulated unconditionally after 17 days, and the national strike proved a fiasco and caused much bitterness against the Radical leaders and Moscow. The Conservative position was strengthened; yet in June 1921 the Government was defeated on the Prohibition question and resigned.

In Oct. 1919 a referendum had sanctioned the temporary prohibitions of 1916 and 1917 by 489,660 votes to 305,241, over 400,000 votes not being cast. But the policy produced a trade war with Spain and Portugal, which cost Norwegian shipowners and the whole fishing population heavy losses. Smuggling, too, increased enormously as did secret home distilling. The Prohibitionists, supported by the Left, Labour and Socialists, replied by greater severity.

The elections of 1921, on the revised basis, gave 57 seats to the Conservative-Liberal coalition, 39 to the Left, 29 to the Labour Party, 8 to the Socialist and 17 to the new Farmers' Party. The Government, although it had lost seats and votes, remained in power, the Left holding the balance between Conservatives and Labour. Otto Blehr, who had succeeded Halvorsen, failed, and a second Halvorsen Government (March 1923) sanctioned the importation of port and sherry. A new treaty was concluded with Portugal, and the commercial war with Spain came to an end. The importation and sale of wines and brandies is now a monopoly under Government control. The shareholders get 6%, the surplus (in 1925 5,000,000 kroner) goes to public funds. The temporary measure enforcing public arbitration in industrial disputes expired in April 1923 and was not renewed. In May 1923 Halvorsen died. His minister of finance, Berge, who succeeded on an insecure majority, endeavoured to replace prohibition by a well-controlled sale of highly-taxed brandies. The Left, Labour and some of the Farmers' Party, however, stood out for another referendum and Berge gave place to J. L. Mowinckel.

In the fall of 1923 the Norwegian Labour Party withdrew from the Third International; whereupon their left wing organized the Communist Party, which remained affiliated with Moscow. At the election of Oct. 1924 the Social Democrats secured 8 seats, the Labour Party 24 and the Communists 6, the Left numbered 36, the Conservative coalition 54, and the Farmers' Party 22. The Conservative Parties thus had a majority of two in the new

storting; but as the Farmers' Party refused to form an active coalition the Mowinckel Government retained office till March 1926, when they were defeated on the budget and succeeded by a Conservative cabinet under Lykke. The municipal elections of Nov. 1925 also brought victories to the "bourgeois" parties at the expense of Labour, and even more of the Communists.

The Spitzbergen archipelago had from time immemorial been under the suzerainty of Norway, but the discovery of coal caused various international conferences to be held in Oslo. The Versailles Treaty gave this group of islands and Beeren Island to Norway (1925). On March 4, 1920, the *storting* resolved that Norway should join the League of Nations. In the following years there was some friction with Denmark concerning Greenland, which had belonged to Norway until 1814. Norway had always resented its loss, and its east coast had been regarded as the fishing and hunting ground of her west coast population. Denmark's request in 1919 for recognition by the Powers of Danish suzerainty over the whole of Greenland led to a separate agreement between the two countries, both agreeing to regard the east of Greenland as no-man's-land *vis-à-vis* the other. Treaties of unconditional arbitration were concluded with various Powers (Germany, Uruguay, etc.) from 1924 onwards.

Since, despite all progress, Norway remains a relatively small, scattered and isolated nation, its political history still depends largely upon economic and financial conditions. The unrest due to the World War is to some extent perpetuated by the existence of a highly educated class more numerous than are the openings for professional employment within the country. The task of 1926-27 continued to be the restoration of the pre-war equilibrium. The connection of the extreme Socialists with Moscow, indeed, inspired a national attempt to place Dr. Nansen, the explorer, at the head of a non-party government. Failing this, Lykke returned to office early in 1926, with a programme of economic and financial reconstruction. In July, the discovery that during the crisis of 1923-24 Berge had secretly supported the Handelsbank with state funds and a guarantee for 40,000,000 kroner led to the impeachment of himself and his colleagues, though the patriotism of his motives was not in question. A verdict of guilty in any particular would have involved the condemnation of the accused to pay at least 1,000,000 kroner until, during the trial itself, the law was so altered as to give the court a reasonable discretion. All of them however, were acquitted on every count (March 1927). Meanwhile a referendum (Oct. 1926) had shown that although the number of votes cast for Prohibition had increased since 1919, the majority of 184,344 was now replaced by a minority of 108,043. A Government committee therefore recommended that adults should be empowered to buy liquor with an alcoholic strength exceeding 21% and in May 1927, Prohibition ended on these terms. The sale was entrusted to incorporated societies and restricted to the hours between 11 A.M. and 5 P.M. At the same time arbitration in industrial disputes was made compulsory, in spite of the strenuous resistance of Labour. In Jan. 1927 a new united Labour Party had been formed. The Moscow-led Communists were excluded, but in June when the Soviet minister at Oslo charged Britain with responsibility for the murder of his colleague in Poland, Madsen, its leader, defended the Soviet reprisals, declaring that the lives of 20,000 Soviet hostages were not equal to that of a single Communist. The *storting* condemned Madsen by nearly four to one, and the police raided the offices of Communist newspapers for seditious propaganda among the British fleet. The autumn elections reduced the Communist deputies to 3, but Labour gained 27 seats and attained a strength of 50. Conservatives and Liberals numbered 32; Farmers' Party, 26; Radicals, 29; and Labour Democrats, 1.

After a prolonged crisis in which both Farmers and Liberals declined office, a Labour Government, under Christopher Harnarud, was formed (Jan. 26, 1928). This declared that the interests of the workers were paramount, and that it would prepare for complete disarmament and the Socialist State. Widespread panic followed, and the Norwegian Credit Bank was for a time in danger. The Labour Government survived, however, for only a

fortnight, yielding place to Mowinckel and the Liberals. On May 1 the gold standard was re-introduced. On March 21, 1929, Crown Prince Olaf of Norway was married at Oslo to Princess Martha of Sweden, the ceremony being performed amid scenes of the greatest public enthusiasm.

NORWAY, a city of Dickinson county, Michigan, U.S.A., in the southern part of the Upper Peninsula, on the Chicago and North Western railway and Federal highway 2, near the Menominee river. The population was 4,533 in 1920 (36% foreign-born white). Iron-mining and lumbering are the principal interests.

NORWEGIAN LANGUAGE AND LITERATURE.

The language used in almost all great newspapers, in commerce and by the best known authors differs in many ways from the spoken language even of people of literary education, still more from that of less educated classes in the towns and of the rural population. "The ordinary literary language," as it is officially styled, or the "Norwego-Danish" as it is scientifically termed, or "*Riksmåal*" in colloquial speech, is the Norwegian variety of the Danish language which came in during the union with Denmark (1380-1814).

Up to the beginning of the 19th century Danish in Norway was chiefly a written language, its oral use being limited to reading, preaching and, towards the end of this period, society purposes. During the 19th century the upper classes, especially of the towns, developed a spoken Norwego-Danish, with Norwegian sounds and intonation, and progressively influenced by the Norwegian popular idiom. Pure Danish was spoken by some actors as late as 1880. In 1887 Norwego-Danish was recognized for standard reading in the secondary schools, and gradually it penetrated even the church, the last stronghold of the Danish tradition. In 1907 some important characteristics of Norwegian pronunciation were adopted into the orthography of the language, and in 1917 orthography took a further step away from modern Danish.

Colloquial Varieties.—The colloquial form varies greatly according to the locality and the social class of the speaker. Locally Norwego-Danish speech may be divided into four principal dialects: the southern dialect, comprising the towns Arendal, Christianssand and Stavanger and others on that part of the coast, with *b-d-g* for Norwegian *p-t-k* following a vowel; the western dialect (Bergen), with a peculiar accent and great fluency of diction, and with the same (uvular) *r* as the southern dialect; the northern dialect (Bodø Tromsø) with a somewhat monotonous "singing" accent; and the eastern dialect (Oslo-Trondhjem), now the principal form of the spoken Norwego-Danish.

This Norwego-Danish literary language, with its dignified pronunciation especially as heard in the capital, is presented as "Norwegian" in school and reference books written for foreigners. Through different social strata this language is connected with the dialects of the towns and of the factory workers in the country. These town dialects exhibit the same phonetic and inflectional traits as the surrounding country dialects and are thus fundamentally Norwegian; but they are susceptible of modifications in the direction of the Norwego-Danish speech of the upper classes. There are thus three strata in the speech of the towns: upper, middle and lower class dialects, the first originally Danish, the last essentially Norwegian. The town dialects are little represented in literature, being limited to writings of a light and humorous kind; modern authors, however, frequently use the colloquial (middle class) and vulgar forms of speech in dialogues and as a means of characterization, and on the stage. Only exceptionally has it found its way into serious drama.

New Norwegian.—The New Norwegian National Language (*Landsmaal*) is a common standard literary form for the dialects, propounded on a scientific basis by Ivar Aasen (1813-1896) in his grammar of Norwegian speech (1848, 1864) and in his *Dictionary* (1850, 1873), and since 1853 cultivated in literary works. From that time the *Landsmaal* has been further developed by a series of authors, by newspapers, by periodicals, by scientific and

educational works (especially on national philology and history, on pedagogics and theology), and by school books of all kinds.

Landsmaal is supported by the national democratic parties and a strong Young People's Association movement. In 1885 the Storting passed a resolution declaring the equality of the popular language and the Norwego-Danish language. In 1892 the school circuits were allowed to make *Landsmaal* the principal language of the elementary school; and it has been adopted by more than 2,000 school circuits, mostly in the west and midland districts, and by the great majority of the free adult schools. In the secondary schools and, from 1908, in the university, students may use *Landsmaal*, but only in three State schools is it the principal language; and in some other secondary schools founded by private individuals or corporations. In some 200 churches the liturgy is in Norwegian, and an increasing number of clergymen preach in Norwegian.

In the districts from Møre to Telemark, statutes have been promulgated in *Landsmaal*. Two hundred district authorities have asked that the central administration and the Government officials use *Landsmaal* when writing to them. Since 1894 the Storting has voted a few laws in Norwegian.

The official orthography of the names of towns, districts, estates and other localities is now in course of revision in order to do away with the Danicized forms and establish an orthography corresponding with their national origin and pronunciation.

Dialects.—Dialect differences are not great enough to prevent intercourse between people of different provinces. Some dialects exhibit strongly marked peculiarities, e.g., that of Setesdal with its diphthongization of old long vowels and its characteristic vocabulary. The country dialects are eastern, western and northern, with many transitional forms especially in the coast districts. The vocabulary is not uniform, and some of the dialects have simplified inflection; but the chief differences are due to the varying development of sounds. The eastern groups have cacuminal and supradental sounds; the northern and greater part of the country palatalizes *nn*, *ll*, *dd*, *gg*; eastern and northern dialects and still others have to a great extent assimilated *nd*, *ld*, *ng*, *gn*, *mb*. In eastern dialects *rd* is mostly pronounced [ʔ] (thick l), in western [r]. Other assimilations are still more widespread, such as *rn* to [nn].

The Character of New Norwegian.—*Landsmaal* is rooted in old Norse. The principal features of the spoken language are the same; it has kept up the old diphthongs and to a great extent the old West Scandinavian vocal system of the stem syllables, differing in this respect from Swedish and Danish (the chief exceptions being rather important changes in the original short syllables, the weakening of sounds in terminations, especially of adjectives, and a certain number of apocopes).

Vocabulary.—The vocabulary is extremely rich, especially in the midland, western and Trøndelag dialects, but it varies greatly from coast districts to mountain and forest districts. It has many literary words, frequently compounds or words of a wider meaning than that given to them in popular speech; these are sometimes termed neologisms and are used as substitutes for established foreign literary and technical terms. While as a spoken and popular language, *Landsmaal* is more puristic than Swedish and Danish; a number of loan-words come from Old Norse, being borrowed from and through Old English, Old French, and, in the latter period of the Middle Ages, from Low German (the Hanse), and in later times through Danish, from High German. Many Danish words, especially such as belong to the field of religion, found their way into Norwegian, although their number is smaller than might have been expected.

LITERATURE

From a linguistic and artistic aspect the literature of ancient Norway is inextricably bound up with Icelandic; Old Norse literature is, therefore, dealt with under Iceland (*q.v.*); yet it should not be forgotten that the psychological features revealed through the so-called *Older Edda*, as well through the sagas, are so typically Norwegian in all essentials that this literature forms the very basis on which the literary fabric of Norway has been raised in the course of centuries.

The literature of the Old Norse language came to an end in the beginning of the 14th century simultaneously with the decline and fall of Norway as a sovereign State with a culture of her own. The chief characteristic of this literature, formed as it was in "an age of axes, an age of swords," is the remarkable fighting spirit by which it is pervaded, and which quite naturally makes it abound in dramatic scenes and striking personalities; at the same time, in poetry as well as in prose, it is imbued by a serene view of life, which reveals a remarkably high moral standard. Another very distinct feature is its decidedly aristocratic leaning, with a pronounced hero-worshipping tendency, as might be expected in an age when the king generally appeared surrounded by his faithful chieftains, and frequently with a young poet before him, singing his praises in glowing terms.

The Literary Revival.—Meanwhile the political union between Denmark and Norway (concluded in 1380) gradually brought Danish nobles and officials to the front in this country, with the result that the Old Norse language was replaced by Danish. This development which constitutes perhaps the most remarkable event in the cultural history of the nation, may be considered as completed by the middle of the 16th century. Accordingly, when about the same time the literary revival set in, which to some extent is due to the introduction into Norway of the Lutheran Reformation, the new literature came to be composed in the Danish language, which for nearly three centuries

was to hold an unchallenged position as the official language of Norway.

The first outcome of the revival of literary interest in Norway was the appearance of the first book ever printed in Norway, an almanac, printed in Christiania in 1643. During the following years Christen Bang (1580-1678) published a number of religious tracts and also a *Description of Christiania* (1651), which at that time had only recently completed the 25th anniversary of its foundation. These curiosities have, however, nothing to do with literature in the true sense of the word, and the first name of importance in Norwegian literature after the spiritual revival in the Reformation century was Peder Claussøn (1545-1614), a clergyman by profession and at the same time a highly gifted author who by his translation of Snorre Sturlassøn (*q.v.*) as well as by his independent works on Norway, has got a lasting reputation. The next striking personality in Norwegian literature is Petter Dass (1647-1708) whose *Nordlands Trompet* (Clarion) with its lyric-topographical description of the scenery and life of north Norway is still considered one of the gems of Norwegian literature. On the other hand, Dorothea Engelbrechtsdatter (1635-1716), who among her contemporaries enjoyed a great reputation as an author of religious poetry, is now practically forgotten owing to the melancholy tone of her work.

Holberg.—Contrasted with these authors, who all spent their life in Norway, Ludvig Holberg (1684-1754) (*q.v.*) early found his way not only out of Norway, but out of Denmark. Leaving Norway for ever at the age of 21, after having taken his degrees at the University of Copenhagen, he went to England, where he studied for more than 18 months at Oxford, from which he carried with him an indelible impression of England and the English. Later travels brought him to France, Germany and Italy, but wherever he went he lived in the English world of thought and reasoned on the basis of his Oxford experiences. In this way, thanks to his inborn genius and his unbiased mind, he prepared himself for the lifework by which he became 'the founder of modern Norwegian and modern Danish literature. He revolutionized the conception of life in two kingdoms and paved the way for the intellectual and political liberty of the future. His most famous works next to his *Comedies* (see *DRAMA: Norway*) are *Peder Paars* (1719), a heroic poem, the humour and satire of which has stood the test of two centuries; *Niels Klim's Underground Travel* (1741), originally written in Latin, a classic evidence of his mental independence, and finally from the closing years of his life his *Epistles* and *Moral Reflections*, which are the best source of information for Holberg students. Holberg restored the cultural connection between Norway, England and western Europe in general, which had been broken off since the end of the saga period. This fact cannot be emphasized too strongly, for it constitutes the connecting link between the Old Norse literature and the literature of modern Norway, and gives the clue to some of the most outstanding features of the latter, *e.g.*, its independent conception of life and its absolute acceptance of facts, however disagreeable.

English native poets, like James Thomson and Edward Young, had their counterpart in Norway in Christian Tullin (1728-65), a manufacturer and merchant of importance in the business community of Christiania, and a central figure in the extremely sociable life of the city. By his famous poem, *The May-Day* (1758), composed on the occasion of a wedding among "the upper ten" of Christiania, Tullin became the first interpreter in Norwegian literature of the long pent-up love of nature which three-quarters of a century later should find such splendid expression in the poetry of Wergeland.

Det Norske Selskab.—Meanwhile, the importance of Holberg's work, along with a number of other factors, among them a constantly growing awareness of being an individual nation with historical traditions and cultural and economic possibilities, gradually began to prevail. The centre of this movement was Copenhagen, where the Norwegian students, partly graduates staying there in search of employment, felt themselves aliens in the midst of a display of public sympathy which made the name of Norway and the Norwegians resound in a way bearing promise for

the future. In 1772, to mention a particular year of lasting importance in Norwegian literature, the Norwegian poets and other men of letters were so strong in Copenhagen that they formed a society which was to become famous under the name of *Det Norske Selskab* (the Norwegian Society). The two most conspicuous members of this society with whom its name has for ever been associated were Johan Herman Wessel (1742-85) and Johan Nordahl Brun (1745-1816); besides them should be mentioned Claus Fasting (1746-91), Claus Frimann (1746-1829), and his brother Peter Harboe Frimann (1752-1839), as also their younger contemporaries, Jonas Rein (1760-1821) and Jens Zetlitz (1761-1821). No student of Norwegian literature who wants to understand the under-currents in the Norwegian nation in the last 40 years prior to the dissolution (1814), should pass by these poets, among whom Claus Frimann still lives in a few songs of popular reputation. The sovereign talent among them is, however, Wessel (see *DRAMA: Norway*), the spiritual inheritor of Holberg, a champion in the fight against pedantry and prejudices, a *gamin* spirit full of irony and good humour in the midst of adversities.

Norwegian literature has no finer display of comic fiction than his three immortal poems, "The Smith and the Baker," "The Dog-murder" and "The Fork," while a number of his pithy and pointed epigrams have long ago become classic. Nordahl Brun's fame with posterity rests less on the poetic value of his works than on the tradition of his striking personality, which in his lifetime made him the very embodiment of the national aspirations of Norway; his famous song "To Norway, giants' country, hail," still sung, bears witness to it.

The Renaissance of 1814.—In literature this renaissance, in its first stage, was represented by three poets, Henrik Anker Bjerregaard (1792-1842), Mauritz Christopher Hansen (1794-1842) and Conrad Nicolai Schwach (1793-1860). Bjerregaard was famous for his *Sønner av Norge* (Sons of Norway), written in 1820, which for half a century was the national anthem of Norway. His merry musical piece, *A Highland Adventure* (1824), is inspired by a genuine love of nature and a sound common sense.

Wergeland and Welhaven.—The commanding genius of this generation is Henrik Arnold Wergeland (1808-45) (*q.v.*), who, as has justly been said, contrived within the limits of a life as short as Byron's to concentrate the labours of a dozen ordinary men of letters. As a poet he is inspired alike by an intense love of nature. Besides larger poems, among which may especially be mentioned *The English Pilot* (1844), he has written in addition a quantity of lyrics with dramas, essays, historical works and journalistic articles—all stamped by his vivid imagination, his sound common sense and his high moral standard.

His contemporary, Johan Sebastian Cammermeyer Welhaven (1807-73), is primarily known for his highly critical nature, with its keen sense of beauty and harmony. His early poems are associated with his literary clash with Wergeland, but notwithstanding the interest attached to them for their polemic character, the memory of Welhaven as a poet chiefly rests upon his beautiful romances. This romantic movement was evident about 1840 and it is the same spirit which led to the discovery of the folk-lore, with its wonderful prose and poetry, in which the soul of the nation and the nature of the country faithfully reflected themselves.

The ideal was that every piece of folk-lore should be rendered in the form given to it by the people in the course of time, and here the Norwegian nation was particularly fortunate. At the right moment the two friends, Peter Christen Asbjørnsen (1812-85) and Jörgen Moe (1813-82), whose names are for ever associated with the Norwegian folk-tales which bid fair to challenge the most famous folk-tales in any European country, made their appearance in literature. Asbjørnsen was a first-rate story-teller with a broad, jovial nature; Moe was a true poet with humour and a rare gift of self-criticism. There was also the Rev. Magnus Brostrup Landstad (1802-80), who in 1853 published his famous collection, *Norwegian Folk-Songs*, the poetical part of the Norwegian folk-lore of which the folk-tales constitute the prose. The former are older than the latter, and accordingly differ from them in several ways; but jointly they constitute what up to the middle of last century was "the missing link" between the

eddas and the sagas on one side, and the literature of modern Norway on the other.

The Landsmaal Movement.—Along with this literary revival there also set in a linguistic and historical renaissance of paramount importance to literature as a whole. In 1848 Ivar Aasen (1813-96) published a grammar and in 1850 a dictionary of the Norwegian folk-language, whereby the intimate connection between the peasant dialects of the day and the Old Norse language was revealed in the most convincing way. Some years after Aasen's appearance in literature the famous historian, Peter Andreas Munch (1810-63), published his mighty work, *History of the Norwegian Nation* (8 vols., 1852-63)—an event of paramount importance in the field of literature.

This Romantic movement leading to the foundation of the national stage in Norway, with Bjørnson and Ibsen as the two pioneers (see *DRAMA: Norway*), it is easy to see why both of them turned to the saga period for suitable subjects and characters. At the same time, however, realism had already set in. During the '50s the Rev. Eilert Sundt (1817-75) started his epoch-making investigations of life and manners in the rural districts, which made the Norwegian peasant appear in a light considerably different from that in which he appeared in the flattering illumination of the former "peasant worship." Accordingly, Bjørnson's famous peasant novels, the first of which was *Synnøve Solbakken* (1857), of a decidedly poetical turn, must be described as imbued by romanticism more than by realism so far as the outward surroundings are concerned.

The Big Four.—In 1855 Madame Camilla Collett (1813-95), Henrik Wergeland's sister, published her famous novel, *The Governor's Daughters*, the first true description in Norwegian literature of ordinary life, while at the same time it dealt a heavy blow to the conventional marriage and education of young girls. In this way Madame Collett became a pioneer in the movement for the emancipation of women in Norway to whom both Bjørnson and Ibsen felt themselves indebted. Next to Madame Collett, the fame of the realistic novel is chiefly developed through Jonas Lie (1833-1908) and Alexander Kielland (1849-1906), who, together with Ibsen and Bjørnson, constitute the famous constellation in the golden age of Norwegian literature popularly known as "the big four." Lie is the author of a number of pure, fresh and eminently characteristic novels dealing with various aspects of every-day life within different ranks of society. *The Pilot and his Wife* (1874), *Rutland* (1880) and *Go On!* (1882), should be mentioned in this connection, no less for the spirit of the white sails and foaming sea by which they are imbued, than for their intimate humanity in substance and psychological analysis. The latter qualities are also splendidly displayed in *The Commander's Daughters* (1886) and *Matrimonial Life* (1887), which, together with his beautiful novel, *The Family at Gilje* (1883), a master-piece of historical review and human psychology dealing with life and characters of the '40s, rank among the crowning works of Lie's extensive authorship. Contrasted with Lie, whose highly impressionistic style not infrequently becomes colloquial to a fault, Kielland is a sovereign master of form, and at the same time a keen psychologist with a decided vein of irony and a heart full of compassion for human suffering. His social novels, *Garmann and Worse* (1880) and *Skipper Worse* (1882), have long ago become classic, as have a number of his short stories, which by their delicacy of style represent the highest attainment of modern Norwegian prose.

Among other authors from the same epoch should be mentioned Kristian Elster (1841-81), who showed great talent in his pessimistic novels, *Tora Trondal* (1879) and *Dangerous People* (1881), and Amalie Skram (1847-1905), wife of the Danish novelist, Erik Skram, whose novels, while deficient in literary beauty, are of a considerable crude force and excellent in their local colour, dealing chiefly with Bergen and west coast life. The outstanding feature of all the authors of the '80s, which may broadly be described as an age of entirely prosaic writers, is the "problem setting," to which there is no parallel in Norwegian literature, and to which Bjørnson himself contributed in his great novel, *Town and Harbour Besieged* (1884), to mention one of the most

typical "problem" novels of the age.

Vinje and Garborg.—The *landsmaal* literature produced two remarkable authors, Aasmund Olafsen Vinje (1818–70) and Arne Garborg (1851–1925). Vinje was a man of rare gifts, a fine lyric poet, a brilliant essayist and a keen critic, who exercised a great influence on Ibsen in his first period as a dramatist and who, broadly speaking, was one of the most striking literary figures of the '60s. Garborg, who was brought up under sternly pietistic influences in the south-west corner of Norway known as Jaeren, carried with him from these surroundings a gloomy view of life, but being at the same time a revolutionary spirit and an imaginative thinker with a considerable training, principally as a critic, he seemed predestined to make his appearance in literature. His great novel, *Peasant Students* (1883), is of a polemic nature. This novel, like the rest of Garborg's novels through the '80s, is written in the *landsmaal*, which at the time to a certain extent was a drawback to their circulation. In 1891, however, he suddenly turned to the *riksmaal* in his extraordinary novel, *Tired Men*, an exquisite example of Norwegian prose.

Hamsun.—Meanwhile another author had already made his appearance in Knut Hamsun (b. 1859) (*q.v.*), whose powerful romance *Hunger* (1888), marks a new departure in Norwegian literature. He is, in fact, its central figure throughout the '90s in the midst of a number of authors of an entirely different stamp from those of the '80s. The most unmistakable genius was, however, Hans Kinck (1865–1926), to whom we propose to return presently. As a typical feature of the '90s it should especially be mentioned that the art of poetry, which had been practically banished from Norwegian for a number of years, again got its exponents, chiefly in Niels Collett Vogt (b. 1864) and Vilhelm Krag (b. 1871). The sensitive spirit of the age is, however, revealed nowhere more remarkably than in Sigbjørn Obstfelder (1866–1900), whose exquisite poetry, as we can study it in his *Posthumous Works*, is rivalled only by his fascinating prose. In both he gives promise of something new in Norwegian literature which was cut short by his early death. At the same time the *landsmaal* poetry witnessed a revival, chiefly through Per Sivle (1857–1904), an excellent national poet whose poems dealt with the episodes and characters of the saga period.

The most consummate work in the *landsmaal* lyric during the '90s is, however, Garborg's *Haugtussa* (1895), inspired by the strange and impressive scenery of the Jaeren. Thus, at the end of the 19th century, there was a revival both in the *riksmaal* and in the *landsmaal* literature.

The first decade of the 20th century will for ever be memorable for the passing away of the four great classics of the preceding age: Ibsen, Bjørnson, Lie and Kielland. Thereby the field of fiction was thrown open to a new generation of authors, who found themselves confronted with problems essentially different from those which had taxed the attention of the former generation. Norway was no longer the country of consuls, shipowners, vicars, rectors, chamberlains and estate owners, representing official views and opinions against which persons not "made of that self metal" occasionally revolted, and always with deplorable result to their own social interests; nor was Norway the country of women suffering in silence under slow torture of an apparently correct marriage, or a country of workers imbued by a patriarchal respect for their employers, based on personal connections from generation to generation. She was a community in which democracy had established itself on a broad basis.

Recent Literature.—No dramatic work of lasting influence has appeared since the age of Ibsen and Bjørnson, but an examination of the history of the Norwegian novel leaves a more satisfactory impression. Hamsun produced works, generally written in an exquisite style and filled with an exuberant vitality, of which *Pan* (1895) ranks particularly high. Compared with this work, the *Growth of the Soil* (1917; Eng. trans. 1920), by which Hamsun has become famous all over the English-speaking world, does not approach it in range of passion and in mystic grandeur.

Kinck, who is by all critics admitted to be an author of rare gifts, has not yet received general recognition either at home or abroad. Yet by his daring metaphors, his exuberant passions, his

deep psychology supported by extensive historical studies, he is one of the most intimate guides to the depths of the Norwegian mind. His Hardanger novel, *The Avalanche* (1919–20), is considered his greatest work, but generally speaking he is at his best in the short story. Another classic writer is Trygve Andersen (1867–1920), a self-controlled author with a limited production.

Besides these three poet-artists and classics should be mentioned Johan Bojer (b. 1872), whose novels, notwithstanding their fame in the English-speaking world and elsewhere, are not considered by Norwegian critics as revealing any particular feature typical of the Norwegian mind. A more intimate author is Peter Egge (b. 1869), a conscientious writer with an artistic style which adds to his original gifts as a narrator and psychologist. These qualities are happily displayed in *Hanna Solstad* (1926), one of the finest novels written in recent years.

The most remarkable figure in recent Norwegian literature is, however, Madame Sigrid Undset (b. 1882) (*q.v.*), who holds a position of her own by her mighty cycles of historical novels, of which *Kristin Lavransdatter*, i–iii., shows a remarkable psychological insight and a rare power of appreciating bygone ages.

One of the chief characteristics of Norwegian literature during the last generation is the ever-increasing number of local authors who, substituting particular districts for the country as a whole, have given rise to local literature, partly written in the literary tongue of the country known as the *riksmaal*, partly in the *landsmaal*, or in a *riksmaal* coloured to a marked degree by local dialects. The most conspicuous of these authors are Oskar Braaten, Hans Aanrud (b. 1863), who scored success as a playwright of broad humour in the '90s, and Johan Falkberget (b. 1879)—all typical East Norway novelists. Braaten's literary domain, not only as a playwright but as a novelist, is the industrial quarters of Oslo and its surrounding districts. Aanrud is a keen observer of life and manners in the midland countries round Lake Mjøsen. Falkberget is intimately acquainted with the miners of the mountain districts of the valley of Østerdalen.

Gabriel Scott has, in an idyllic novel, *The Source* (1918), found an exquisite expression of the typical Sörland (literally Southerland) nature and Sörland temper as they reveal themselves all through the charming coastland. West Norway country life has been ably sketched by Jens Tvedt (b. 1857), who writes in the *landsmaal*. The particular district of the North Trondhjem country, known as the valley of Namdalen, has in Olav Duun (b. 1876), whose works all deal with life and manners in his native valley, produced the most gifted author of modern times writing in the *landsmaal*. Another significant author in the same language is Kristofer Uppdal (b. 1878), originally a navvy, whose works are imbued by the ideals of the labour movement.

In poetry Niels Collett Vogt has continued to proclaim his emotions in stanzas of vigorous and beautiful metaphors. Olaf Bull (b. 1882) combines to a rare degree a refined versification with silent resignation and lofty enthusiasm. Herman Wildenvey (b. 1885), a genial troubadour talent, sings out his joys, his cares and his whims in easy verses and metaphors, striking for felicity of phrase. Simultaneously with this lyric flourishing in the *riksmaal*, no adequate revival has taken place in the *landsmaal*. The gem of lyric poetry in that tongue is still *Haugtussa*, a lasting tribute to the genius of Arne Garborg, by whose death the *landsmaal* literature lost its first rare lyric poet.

"Norway's Literature from the Reformation to 1814" (by Professor Bull).

NORWICH (nō'rīj), **GEORGE GORING**, EARL OF (1583?–1663), English soldier, son of George Goring of Hurstpierpoint and Ovingdean, Sussex. He was knighted in 1608, and became a favourite at court, benefiting largely from monopolies granted by Charles I. He became Baron Goring in 1628, and privy councillor in 1639. When the troubles between Charles and his

parliament became acute Goring devoted his fortune freely to the royal cause; and the king in November 1644 renewed for him the title of earl of Norwich which had become extinct at his uncle's death. He went with the queen to Holland in 1642 to raise money for the king, and in the autumn of the next year he was seeking arms and money from Mazarin in Paris. His proceedings were revealed to the parliament in January 1644 by an intercepted letter to Henrietta Maria. He was consequently impeached of high treason, and prudently remained abroad until 1647 when he received a pass from the parliament under a pretext of seeking reconciliation. Thus he was able to take a prominent part in the Second Civil War of 1648 (*see* GREAT REBELLION). He commanded the Kentish levies, which Fairfax dispersed at Maidstone and elsewhere, and was forced to surrender unconditionally at Colchester. He was condemned to death on March 6, but petitions for mercy were presented to parliament, and Norwich's life was spared by the Speaker's casting vote. He then joined the exiled court of Charles II., by whom he was employed in fruitless negotiations with the duke of Lorraine. He became captain of the king's guard at the Restoration, and in consideration of the fortune he had expended in the king's service a pension of £2,000 a year was granted him. He died at Brentford on Jan. 6, 1663.

NORWICH, city and county town of Norfolk, England, 114 m. N.E. by N. from London. Pop. (1921) 120,661. It is served by the L.N.E., the L.M.S., and the M. and G.N. railways. Caistor-by-Norwich, 4 m. S. of Norwich, is on the site of what was probably a Romano-British town. According to tradition Uffa made a fortification here about 570, but its history as a royal borough cannot be traced before the reign of Aethelstan (924-940), when it possessed a mint. After being destroyed by the Danes Norwich enjoyed a period of prosperity under Danish influence and was one of the largest boroughs in the kingdom at the Conquest. Ralph de Guader, earl of East Anglia under William I., formed the nucleus of a French borough with different customs from the English, and after his forfeiture a castle was built and the centre of burghal life gradually transferred to the new community west of it. By 1158, when Henry II. granted the burgesses a charter confirming their previous liberties, the two boroughs seem to have amalgamated. A fuller charter given by Richard I. and confirmed by later sovereigns made Norwich a city enjoying the same liberties as London. The city lies in the valley of the Wensum, which joins the Yare immediately below. The ancient city lay in a deep bend of the Wensum, and the walls (1294-1342), with their many towers and 12 gatehouses, of which fragments only remain, were 4 m. in circuit. These narrow limits, however, were outgrown even by 1671. The castle, standing high upon a steep mound, is still partly surrounded by earthworks and a ditch spanned by a very early bridge. Only the early Norman square keep remains, with four tiers of arcading without, and an ornate doorway into the great tower. The building was acquired in 1884 by the corporation and in 1894 adapted as a museum and art gallery.

The cathedral church of the Holy Trinity lies between the castle and the river. In 1094 the seat of the East Anglian bishopric was removed by Bishop Herbert de Lozinga or Lorraine from Thetford to Norwich, where in 1096 he laid the foundation of the cathedral and dedicated it in 1101, establishing at the same time a Benedictine monastery. As completed by his successor before the middle of the 12th century the cathedral was purely Norman; and it still retains its original Norman plan. The Early English lady chapel (demolished about 1580) belonged to the middle of the 13th century; the Perpendicular spire, erected after the collapse of two spires of wood, belongs to the 15th; the west window and porch and the lierne stone vaulting of the nave, with its 328 bosses, to the 15th, and to the 16th the vaulting of the transepts and Bishop Nix's chantry, whilst the fine cloisters, with 45 windows, were begun in 1297 and not completed till 1430. The chief entrance on the west is a Perpendicular archway, above which is a window filled with modern stained glass. The nave is divided by 14 semicircular arches, whose piers are in two instances ornamented with spiral mouldings. The triforium is composed of similar arches. The choir is of unusual

length, and terminates in an apse. The oak stalls and *misereres* are of the 15th century. Of three circular apsidal chapels two remain. Two richly sculptured gateways lead to the cathedral—the Erpingham gate (1420) and the Ethelbert gateway (c. 1300). The bishop's palace and the deanery have undergone many alterations. The latter has a well-restored chapel. An Early Decorated ruin in the palace garden, known as "Bishop Salmon's gateway," is supposed to have been the porch to the great hall (c. 1319).

The citizens obtained a charter (1404), making their city a county with a mayor and two sheriffs instead of four bailiffs, and Henry V. added 24 aldermen and 60 common councilmen (1418). The cathedral precinct became parcel of the city at the Dissolution and in 1556 the neighbouring hamlets were incorporated in the county of Norwich. The charter of Charles II. (1683) remained in force till 1835, when one sheriff was removed and the number of aldermen, common councilmen and wards diminished. Since 1298 Norwich has been represented in parliament by two members. Two annual fairs, existing before 1332, were formally granted to the city in 1482. One was then held in Lent, the other began on the feast of the Commemoration of St. Paul (June 30). These have been succeeded by the Maunday Thursday horse and cattle fair, and the pleasure fairs of Easter and Christmas. The market, which must have existed before the Conquest, was held daily in the 13th century, when citizens enclosed stalls by royal licence. Edward III. made Norwich a staple town, and the importance of its trade in wool and worsted dates from his reign.

The majority of the Norwich churches are of Perpendicular flint work, mostly of the 15th century. At Carrow, east of the city, there remain the hall, a doorway, and other fragments of a Benedictine nunnery. The house in which Borrow resided with his parents when in Norwich is now a Borrow museum, presented by A. M. Samuels in 1913. The Stranger's Hall, a 15th century house on Charing Cross, was given as an English Folk museum by L. G. Bolingbroke. In 1921 Sir Eustace Gurney presented to the city the Lazar House, a Norman relic contemporary with the cathedral, for the purpose of a branch public library. In 1925 Miss E. M. Colman, the first lady in England to be Lord Mayor, and her sister restored and presented to the city the 14th century Suckling House.

The grammar school is a Decorated edifice, formerly a chapel of St. John, of c. 1316, with crypt below. Sir Edward Coke, Lord Nelson, Raja Brooke and George Borrow were educated here. St. Andrew's Hall is the seven-bayed nave of the Black Friars' church, rebuilt with the aid of the Erpinghams between 1440 and 1470. It is Perpendicular, with 28 clerestory windows and chestnut hammer-beam roof, and has served since the Reformation as a public hall. It was restored in 1863. The guild-hall, on the site of an earlier tolbooth, is a flint Perpendicular structure of 1408-13; the mayor's council-chamber, with furniture of the time of Henry VIII., is a specimen of a court of justice of that period. The city regalia, kept here, include several objects of historical interest, amongst them a sword of a Spanish admiral captured by Nelson, with his autograph letter presenting it to the city, and a curious figure formerly used in the procession of the mayor elect through the city. The Norfolk and Norwich library was rebuilt in 1900 after a fire. The charitable institutions include St. Giles's or old men's hospital (an ancient foundation), and Doughty's hospital (1687).

Norwich is extending and enlarging its industries, which include foundries and engineering works, iron and wire fence works, brewing, brick works, chemical works, tanneries, and the production of mustard, starch, malt vinegar, and crêpe, gauze and lace; and there are large boot and shoe factories. The great cattle market lies below the castle. The chief magistrate was created lord mayor in 1910.

NORWICH, a city of south-eastern Connecticut, U.S.A., situated at the confluence of the Yantic and the Shetucket rivers to form the Thames. It is served by the Central Vermont and the New York, New Haven and Hartford railways and steamers to New York. Pop. (1920) 22,304 (26% foreign-born white); 1928 local estimate 26,000. It is the seat of a State hospital for

the insane and a State tuberculosis sanatorium. Under a monument in Sachem street is buried the Mohegan chief Uncas, a friend to the early settlers; and in the eastern part of the city is a monument to Miantonomo, a Narragansett sachem who was put to death here. The channel of the Thames is 14 ft. deep to Norwich. Its manufactures are varied, including cotton and woollen goods, velvets, fire-arms, thermos bottles, locks, leather and rubber goods, buttons, trunks, boilers and many kinds of machinery. The aggregate output in 1925 was valued at \$20,908,609. Norwich was settled in 1659 by colonists from Saybrook, led by Capt. John Mason, who had crushed the Pequots in 1637, and the Rev. James Fitch, who became a missionary to the Mohegans. The land was bought from three Mohegan chiefs, and until 1662 the settlement was called Mohegan. It was the home of the Huntington family, which furnished many leaders in the civil and military affairs of the Colony, the State and the nation; and the birthplace of Benedict Arnold, Mrs. Lydia H. Sigourney and Donald G. Mitchell ("Ik Marvel"). Before and during the Revolution the people of Norwich were ardent Whigs, boycotting English goods in 1767, ostracizing a schoolmaster (1770) who continued to drink tea, and disregarding the Stamp Act in 1776. The town was chartered as a city in 1784. The *Courier*, a newspaper established in 1796, is still published.

NORWICH, a city of New York, U.S.A., on the Chenango river and the Chenango trail, 42 m. N.E. of Binghamton; the county seat of Chenango county. It has an airport, and is served by the Lackawanna and the New York, Ontario and Western railways. Pop. (1920) 8,268 (89% native white). Norwich is a manufacturing city, in one of the principal dairying districts of the State. Its leading products are pharmaceutical preparations, condensed milk, silos, wire baskets, silk and knit goods, hammers and hangars. There are railroad shops here. Norwich was settled in 1792, incorporated as a village in 1857 and as a city in 1915.

NORWOOD, a residential area of London, England, partly in Surrey and partly in the county of London (metropolitan borough of Lambeth). The district is hilly and well wooded. It is divided into Upper, Lower, South and West Norwood.

NORWOOD, a town of Norfolk county, Massachusetts, U.S.A., 14 m. S.W. of Boston, on the Neponset river and served by the New York, New Haven and Hartford railroad. Pop. (1920) 12,627 (34% foreign-born white), 14,151 in 1925 (State census); 1928 local estimate 15,000. It is a residential suburb, and it has important manufactures, notably the plants of three large printing and publishing houses. Norwood was incorporated (from parts of Dedham and Walpole) in 1872. Since 1915 it has had a municipal-manager form of government.

NORWOOD, a city of Hamilton county, Ohio, U.S.A., adjoining Cincinnati on the north-east. It is served by the Baltimore and Ohio, the Pennsylvania and (for freight) the Norfolk and Western railways. Pop. (1920) 24,966 (93% native white); estimated locally at 35,000 in 1928. Developed originally as a residential suburb, it now has extensive manufacturing industries, with an output in 1925 valued at \$57,217,181. Playing cards, office furniture, safes, stationery, electric goods, pianos, tools and house furnishings are leading products, and there are large printing and lithographing establishments. Norwood was founded (as Sharpsburg) about 1798, laid out in 1873, incorporated as a village in 1888 and chartered as a city in 1903.

NOSARI or **NAVSARI**, a town in India, in the state of Baroda, and the capital of the Gaekwar's southern possessions. It lies on the left bank of the Purna river, 147 m. by rail N. of Bombay. Pop. (1921) 19,437. It is an ancient place, known to Ptolemy as Nasaripa. It was one of the earliest settlements of the Parsees in Gujarat, after their banishment from Persia in the 12th century. It is still the home of their *mobeds*, or sacerdotal class, and contains their most venerated "fire temple." The public buildings and the private houses, especially those in the suburbs, are unusually good.

NOSE, the organ of the sense of smell (*q.v.*) in man and other animals (see **OLFACTORY SYSTEM**).

NOSOLOGY, that branch of medical science which deals with classification of diseases; also, a collection of diseases.

NOSSI-BÉ, properly Nòsy-bé, *i.e.*, "Great island," an island about 8 m. off the N.W. coast of Madagascar, in 13° 23' S., 48° 15' E. It has an area of 130 sq.m. Nossi-bé is volcanic, the North and South parts of older, the central part of more modern date. There are numerous volcanic craters and crater-lakes. (Lòkobé, the highest point, is 1,486 ft. above the sea.) The climate is trying, but European colonization is, nevertheless, highly developed. Pop. about 10,000. Hellville, the chief town (pop. 2,500) is a port of call for the Messageries Maritimes and a centre for the coasting trade along the western shores of Madagascar. There is excellent anchorage. The soil is very fertile, and there are forests of palms and bamboos. The chief products are coffee, the sugar-cane, cocoa, vanilla and tobacco. There are numerous sugar factories and rum distilleries. Shellfish, shells, mother of pearl, pearls and sponges are objects of trade.

In 1837 Tsioméko, chieftainess of one of the numerous divisions of the Sàkalava, was expelled by the Hova and fled to Nossi-bé and to the neighbouring islet of Nossi-komba. She accepted French protection in 1840, ceding such rights as she possessed on the N.W. coast of the mainland. The French took possession in 1841. Nossi-bé is placed under the administration of Madagascar (*q.v.*).

NOSTRADAMUS (1503-1566), the assumed name of MICHEL DE NOTREDAME, French astrologer, of Jewish origin, who was born at St. Remi in Provence on Dec. 13, 1503. After studying humanity and philosophy at Avignon, he took the degree of doctor of medicine at Montpellier in 1529. He settled at Agen, and in 1544 established himself at Salon near Aix in Provence. Both at Aix and at Lyons he acquired great distinction by his labours during outbreaks of the plague. In 1555 he published at Lyons a book of rhymed prophecies under the title of *Centuries*, which secured him the notice of Catherine de' Medici; and in 1558 he published an enlarged edition with a dedication to the king. The seeming fulfilment of some of his predictions increased his influence, and Charles IX. named him physician in ordinary. He died on July 2, 1566.

The *Centuries* of Nostradamus have been frequently reprinted, and have been the subject of many commentaries. Nostradamus wrote a number of smaller treatises. See Baresté, *Nostradamus* (Paris, 1840).

NOTARY or **NOTARY PUBLIC**. In Roman law the *notarius* was originally a slave or freedman who took notes (*notae*) of judicial proceedings in shorthand. The modern notary corresponds rather to the *tabellio* or *tabularius* than to the *notarius*. In canon law it was a maxim that his evidence was worth that of two unskilled witnesses.

The office of notary in England is a very ancient one. It is mentioned in the Statute of Provisors, 25 Edward III. stat. 4. The English notary is an ecclesiastical officer, nominated, since the Peterpence Dispensations Act 1533-34, by the archbishop of Canterbury through the master of the faculties (now the judge of the provincial courts at Canterbury and York), in order to secure evidence as to the attestation of important documents. All registrars of ecclesiastical courts must be notaries. A notary's duties, however, are mainly secular. "The general functions of a notary consist in receiving all acts and contracts which must or are wished to be clothed with an authentic form; in conferring on such documents the required authenticity; in establishing their dates; in preserving originals or minutes of them which, when prepared in the style and with the seal of the notary, obtain the name of original acts; and in giving authentic copies of such acts" (Brooke, *On the Office of a Notary*). The act of a notary in authenticating or certifying a document is technically called a "notarial act." In most countries the notarial act is received in evidence as a semi-judicial matter, and the certificate of a notary is probative of the facts certified. But English law does not recognize the notarial act to this extent. An English court will, in certain cases, take judicial notice of the seal of a notary, but not that the facts that he has certified are true, except in the case of a bill of exchange protested abroad. The file of a year's documents is often termed the protocol.

The most important part of an English notary's duty is the noting and protest of foreign bills of exchange in case of non-acceptance or non-payment. This must be done by a notary in

order that the holder may recover. He also prepares ship protests relating to mercantile matters, and authenticates and certifies copies of documents and attests instruments to be sent abroad. The office of notary is now usually held by a solicitor. In London he must be free of the Scriveners' Company.

In Scotland the office of notary is *munus publicum* and his notarial acts are probative. A roll of notaries public is kept, and under the Law Agents (Scotland) Act, 1873, any law agent is entitled to admission to the roll on payment of additional stamp duty. In addition to noting and protest of bills of exchange, notaries in Scotland have important functions in relation to completion of titles to land. They act as commissioners of the Sheriff Court of Chancery for taking affidavits in the process of service of heirs, they prepare and execute notarial instruments for giving service in land, and they may execute deeds notarially on behalf of persons who cannot write. Notaries also are supposed to keep their protocol books which are probative of the intimation of certain protests by mariners and others. Modern legislation, however, has made serious inroads on the exclusiveness of the notary's functions.

In France, notaries receive all acts and contracts to which the parties thereto must give or desire to give the authenticity attached to the acts of a public authority; they certify the date, preserve the originals and give copies or duplicates. Notaries are nominated by the president of the republic on the recommendation of the keeper of the seals. They cannot act as notaries and also practise as advocates, or hold any magisterial office, nor must they engage in business.

In the more important British colonies and in foreign countries generally notaries are governed by special statutory legislation.

In the United States, the President appoints notaries in the District of Columbia, and the governor alone appoints them in most States. Many states have laws limiting the numbers who may be appointed for a particular county, usually a number in proportion to the population. Notaries are not empowered to act outside their own states, and often not outside their own counties. In most cases their seals must be affixed to the affidavit or other document. They attest deeds and other instruments, take affidavits and depositions and protest bills of exchange. Certain other officials may have notarial functions in addition, such as commissioners of deeds in New York state.

NOTE, a mark, particularly a sign by which a musical sound (also called a note) is indicated in writing (*see* MUSICAL NOTATION). A comment or addition, added to a passage in a book, or a communication in writing shorter or less formal than a letter. The term is also applied to an abstract or memorandum of documents, speeches, etc., especially in the process of the transfer of land by fine and recovery (*see* FINE).

The ordinary distinction between note and letter is reversed in diplomacy. *Diplomatic notes* are written communications exchanged between diplomatic agents or between them and the ministers of foreign affairs of the government to which they are accredited. Sometimes, by agreement, a mere exchange of notes has the force of a convention. *Collective notes* are those signed by the representatives of several powers acting in concert. Sometimes *identical notes* are substituted for collective, *i.e.*, notes identical as to form and substance, but signed and delivered separately by the representatives of the several powers. *Circular notes* are those addressed by one power to the other powers generally. *Confidential notes* are directed to inspiring confidence by giving an explicit account of the views and intentions of the plenipotentiaries and their governments. The so-called *notes verbales* are unsigned, and are merely of the nature of memoranda of conversations, etc. *Notes ad referendum* are addressed by diplomatic agents to their own governments asking for fresh powers to deal with points not covered by their instructions. Diplomatic notes are usually, but not invariably, written in the third person.

For notes of hand or promissory notes *see* NEGOTIABLE INSTRUMENTS and BILL OF EXCHANGE, and for notes passing as currency *see* BANKS, HISTORY OF, BANK-NOTE and POST.

NOTHOMB, JEAN BAPTISTE, BARON (1805–1881), Belgian statesman and diplomat, was born at Messancy in Luxem-

burg on July 3, 1805. He was educated at the Athenaeum of Luxemburg and the university of Liège. He was in Luxemburg when the revolution of August broke out, but was nominated a member of the commission appointed to draw up the constitution. He was a member of the national congress, and became secretary-general of the ministry of foreign affairs under Surlet de Chokier. He supported the candidature of the duke of Nemours, and joined in the proposal to offer the crown to Prince Leopold of Saxe-Coburg, being one of the delegates sent to London. When the Eighteen Articles were replaced by the Twenty-four less favourable to Belgium, he insisted on the necessity of compliance, and in 1839 he faced violent opposition to support the territorial cessions in Limburg and Luxemburg, which had remained an open question so long as Holland refused to acknowledge the Twenty-four Articles. His *Essai historique et politique sur la révolution belge* (1838) won for him the praise of Palmerston and the cross of the Legion of Honour from Louis Philippe. In 1837 he became minister of public works, and to him was largely due the rapid development of the Belgian railway system, and the increase in the mining industry. In 1840 he was sent as Belgian envoy to the Germanic confederation, and in 1841, on the fall of the Lebeau ministry, he organized the new cabinet. In 1845 he retired. He died at Berlin on Sept. 6, 1881.

See T. Juste, *Souvenirs du baron Nothomb* (Brussels, 1882); and F. de Ryckman de Betz, *Le Baron Nothomb et la question Luxembourgeoise* (1918).

NOTICE, a term primarily meaning knowledge as in "judicial notice"; thence it comes to signify the means of bringing to knowledge, as in "notice to quit"; at last it may be used even for the actual writing by which notice is given. The most important legal uses of the word are judicial notice and the equitable doctrine of notice. Judicial notice is the recognition by courts of facts or events without proof. Thus in England and the United States the courts take judicial notice of the existence of States and sovereigns recognized by the sovereign of England, of the dates of the calendar, the date and place of the sittings of the legislature, etc. The equitable doctrine of notice is that a person who purchases an estate, although for valuable consideration, after notice of a prior equitable right, will not be enabled by getting in the legal estate to defeat that right. On the other hand, a purchaser for valuable consideration without notice of an adverse title is as a rule protected in his enjoyment of the property. Other common uses of the word are notice to quit, *i.e.*, a notice required to be given by a landlord to tenant, or by tenant to landlord in order to terminate a tenancy (*see* LANDLORD AND TENANT); notice of dishonour, *i.e.*, a notice that a bill of exchange has been dishonoured; notice of action, *i.e.*, a notice to a person of an action intended to be brought against him, which is required by statute to be given in certain cases; notice of trial, *i.e.*, the notice given by a plaintiff to a defendant that he intends to bring on the cause for trial; notice in lieu of personal service of a writ, *i.e.*, by advertisement or otherwise; notice given by one party in an action to the other, at a trial, to produce certain documents in his possession or power; notice to treat, given under the Land Clauses acts by public bodies having compulsory powers of purchasing land as a preliminary step to putting their powers in force. Notice may be either express or constructive. The latter is where knowledge of a fact is presumed from the circumstances of the case, *e.g.*, notice to a solicitor is usually constructive notice to the client. In the United States the doctrine of constructive notice is particularly important in view of the recording acts subordinating purchasers of real estate who have no actual notice of prior encumbrances on land to those whose rights have been placed on record in the registry of deeds, such purchasers being deemed to have constructive notice of whatever could have been discovered by an examination of the records. (*See* LAND REGISTRATION.)

NOTKER, a name of frequent occurrence in the ecclesiastical history of the middle ages. NOTKER BALBULUS (c. 840–912) was a native of northern Switzerland, and for many years *magister* in the school of St. Gall. He compiled a martyrology and other works, but is famous for his services to church music and for the "sequences" of which he was the composer. He was canonized in

1513. His life is in the Bollandist *Acta Sanctorum*, April 6th. **NOTKER LABEO** (d. June 29th, 1022) was also an instructor at St. Gall. His numerous translations, including those of the Old Testament Psalms, the categories of Aristotle, the *De nuptiis Mercurii et Philologiae* of Martianus Capella, and the *De consolatione* of Boëthius, into Old High German, may possibly have been the work of his pupils. They possess considerable philological interest, and have been edited by E. G. Graff (Berlin, 1837-1847), and by P. Piper under the title *Notkers und seiner Schule Schriften* (1883-1884).

See J. Kelle, *Di Sankt Galler deutschen Schriften und Notker Labeo* (Munich, 1888); G. Meyer von Knorau, "Lebensbild des heiligen Notker," in *Mittel. Antiq. Gesellschaft Zürich* (1877).

NOTO, city, Sicily, province of Syracuse, 20 m. S.W. of it by rail, 520 ft. above sea-level. Pop. (1921) 17,443 (town), 32,336 (commune). The present town, rebuilt after the earthquake of 1693, has some fine buildings of the early 18th century. The older town lies 10 m. direct to the north (1,378 ft.). It was the ancient *Netum*, a city of Sicel origin, left to Hiero II. by the Romans by the treaty of 263 B.C. Little remains but the ruins of the mediaeval town. But four cemeteries of the third Sicel period, and one of the Greek period, of the 3rd and 2nd centuries B.C., have been excavated.

See P. Orsi in *Notizie degli scavi* (1899) 241.

NOTT, ELIPHALET (1773-1866), American divine, was born on June 25, 1773, at Ashford (Conn.). Through his brother's assistance and his own efforts while successfully teaching, he was enabled to pass the Brown college examinations. He was pastor and teacher at Cherry Valley (N.Y.) (1796-97), pastor of the Presbyterian church in Albany (1798-1804), and thereafter president of Union college, Schenectady (N.Y.), a position which he held till his death on Jan. 29, 1866. He found the college financially embarrassed, but succeeded in placing it on a sound footing. He was known also as the inventor of the first stove for anthracite coal. His publications include sermons, *Counsels to Young Men* (1810), and *Lectures on Temperance* (1847).

See *Memoirs of Eliphalet Nott* by C. van Sant Voord (ed. Taylor Lewis, 1876).

NOTT, SIR WILLIAM (1782-1845), English general, was the second son of Charles Nott, a Herefordshire farmer, obtained a cadetship in the Indian army and proceeded to India in 1800. In 1839, he held a command at Quetta and in November 1840 he captured Khelat, and in the following year compelled Akbar Khan and other tribal chiefs to submit to the British. On receiving the news of the rising of the Afghans at Kabul in November 1841, Nott took energetic measures. On Dec. 23, the British envoy, Sir William Hay Macnaghten, was murdered at Kabul; and in Feb. 1842 the weak and incompetent commander-in-chief, General Elphinstone, sent orders that Kandahar was to be evacuated. Nott at once decided to disobey, on the supposition that Elphinstone was not a free agent at Kabul; and as soon as he heard the news of the massacre in the Khyber Pass, he urged the Government at Calcutta to maintain the garrison of Kandahar with a view to avenging the massacre and the murder of Macnaghten. In March he inflicted a severe defeat on the enemy near Kandahar, and in May drove them with heavy loss out of the Baba Wali Pass. In July he received orders from Lord Ellenborough, the governor-general of India, to evacuate Afghanistan, with permission to retire by Kabul. Nott arranged with Sir George Pollock, now commander-in-chief, to join him at Kabul. On Aug. 30 he routed the Afghans at Ghazni, and on Sept. 6 occupied the fortress, from which he carried away, by the governor-general's express instructions, the gates of the temple of Somnath; on the 17th he joined Pollock at Kabul. The combined army recrossed the Sutlej in December. (See *AFGHANISTAN: History*). Nott was appointed resident at Lucknow and received the G.C.B. and a pension. He died at Carmarthen on Jan. 1, 1845.

See *Memoirs and Correspondence of Sir William Nott*, edited by J. H. Stocqueler (2 vols., 1854).

NOTTINGHAM, EARLS OF. The English title of earl of Nottingham has been held by different families, notably by the Mowbrays (1377 to 1475; merged in the Norfolk title from

1397), the Howards (1596-1681), and the Finches (1681; since 1729 united with that of Winchelsea).

HENEAGE FINCH (1621-1682), first earl of Nottingham in the Finch line, lord chancellor of England, was descended from an old family (see **FINCH**, **FINCH-HATTON**), and was the eldest son of Sir Heneage Finch, recorder of London. He was educated at Westminster and at Christ Church, Oxford, and was called to the bar at the Inner Temple in 1645. He was a member of the convention parliament of April 1660, and shortly afterwards was appointed solicitor-general, being created a baronet. He sat in parliament for Oxford. In 1670 he became attorney-general, and in 1675 lord chancellor. He was created Baron Finch in 1674, and earl of Nottingham in May 1681. He died in Great Queen Street, London, on Dec. 18, 1682, and was buried in the church of Ravenstone in Bucks.

His most important contribution to the statute book is "The Statute of Frauds"; he also superintended the edition of Sir Henry Hobart's *Reports* (1671).

He also published *Several Speeches and Discourses in the Tryal of the Judges of King Charles I.* (1660); *Speeches to both Houses of Parliament* (1679); *Speech at the Sentence of Viscount Stafford* (1680). He left Chancery Reports in ms., and notes on Coke's *Institutes*.

NOTTINGHAM, CHARLES HOWARD, 1ST EARL OF (in the Howard line) (1536-1624), English lord high admiral (also known as 2nd Lord Howard of Effingham), was the eldest son of William, 1st Baron Howard of Effingham, lord high admiral. He was nearly connected with Queen Elizabeth, his father's sister, Elizabeth Howard, being mother of Anne Boleyn. In 1559 he was sent as ambassador to France to congratulate Francis II. on his accession, and in 1569 was general of the horse under the earl of Warwick for suppressing the Roman Catholic rebellion in the north. The next year he commanded a squadron to watch the Spanish fleet which came to conduct the queen of Spain from Flanders, on which occasion "His lordship, accompanied with 10 ships only of Her Majesty's Navy Royal, environed their Fleet in a most strange and warlike sort, enforced them to stoop gallant and to vail their bonnets for the queen of England." (Fuller's *Worthies* ii. 361.) In the parliaments of 1563 and 1572 he represented Surrey, and succeeded to his father's title in 1573. He was installed a knight of the Garter in 1574, and made lord chamberlain of the household, an appointment which he retained till May 1585, when he became lord high admiral of England. He also filled the offices of lord-lieutenant of Surrey and high steward of Kingston-upon-Thames. He was one of the commissioners at the trial of the conspirators in the Babington Plot and of Mary, queen of Scots, in 1586.

In Dec. 1587 he hoisted his flag on the "Ark." His letters at this time reflect vividly his sense of the impending danger. "For the love of Jesus Christ, Madam," he writes to Elizabeth, "awake thoroughly and see the villainous treasons round about you, against your Majesty and your realm, and draw your forces round about you like a mighty prince to defend you. Truly, Madam, if you do so, there is no cause for fear." On the approach of the Armada on July 6, 1588, Howard describes thus the disposal of his forces: "I have divided myself here into three parts, and yet we lie within sight of one another, so as if any of us do discover the Spanish fleet we give notice thereof presently the one to the other and thereupon repair and assemble together. I myself do lie in the middle of the channel with the greatest force. Sir Francis Drake hath 20 ships and 4 or 5 pinnaces which lie beyond Ushant and Mr. Hawkins with as many more lieth towards Scilly." He directed the various engagements (see *ARMADA*), and stayed himself to conduct the attack on the "San Lorenzo," stranded off Calais, arriving in consequence at the great fight off Gravelines some time after the engagement had begun. His tactics have been criticized both by contemporary and by later authorities. Instead of risking all in a pitched battle with the enemy, he resolved to pursue the less heroic method of "plucking their feathers little by little"; and his prudence, while justified by the extraordinary results, was also greatly praised by so good a judge as Raleigh. Shortly afterwards, under Howard's directions, a "Relation of Proceedings" was drawn up (now printed in the *Navy Records*

Society Publications, i. 1-18).

In 1596 Howard and Essex commanded the expedition against Cadiz, when a squadron of the enemy's ships was destroyed and two of the number brought home. Essex insisted on landing, and Howard, who had been specially charged by Elizabeth to protect her favourite, was obliged to follow in his support. The town was sacked and the forts destroyed. Howard was created (Oct. 22, 1596) earl of Nottingham.

In February 1598, and again in 1599, when there were fears of invasion, Howard was appointed "Lord Lieut.-general of all England," and exercised full authority both over the army and the navy. He took a leading part in suppressing the rebellion of Essex, and served as a commissioner on his trial in 1601. It was to Nottingham that Elizabeth named James as her successor on her deathbed. He continued to hold office as lord high admiral under the new king, and in 1605 was despatched as ambassador to Spain, where he secured peace. He served on numerous commissions, including those on the union of the two kingdoms in 1604, for the trial of the conspirators of the Gunpowder Plot and of Henry Garnett in 1606, and for reviewing the articles and rules of the order of the Garter in 1618, and he attended Princess Elizabeth on her marriage to the elector palatine with a squadron to Flushing in 1613. Nottingham, who, unlike many of the Howards, was a staunch Protestant, was commissioner in Surrey for inquiring after recusants, and in the diocese of Winchester for hearing ecclesiastical causes; he sat on the government commission for discovering and expelling Roman Catholic priests, and was mentioned in 1602 from Douay as one of the three enemies most feared by the recusants.

On the report of the commission on the navy in 1618 and of the abuses then exposed, Lord Nottingham, though no blame was attached to himself, being now over 80 years of age, vacated his office of lord high admiral. He died at Haling House, near Croydon, on Dec. 14, 1624, and was buried at Reigate, a monument being afterwards placed to his memory in St. Margaret's church at Westminster. He was a striking and almost heroic figure in the Elizabethan annals. By his splendid character and services he was placed beyond the reach of the intrigues which troubled the reputation of many of his contemporaries.

Lord Nottingham married (1), in 1563, Catherine, daughter of Henry Carey, 1st Lord Hunsdon, (2), when in his 68th year, Margaret, daughter of James Stuart, earl of Murray.

NOTTINGHAM, a city and county of a city, municipal and county town of Nottinghamshire, England. Pop. (1921) 262,624.

The highly advantageous position of Nottingham (*Snoten-gaham*, *Notingeham*) on the Trent, where it was crossed by an ancient highway, accounts for its origin. The Saxon form of the name is taken to refer to the caves, anciently used as dwelling-places, which were hollowed out in the Castle rock, in the Rock Holes west of the castle, in the suburb of Sneinton and elsewhere. It was chosen by the Danes for their winter quarters in 868, and constituted one of their five burghs. In 922 it was secured and fortified by Edward the Elder, who in 924 built a second "burgh" opposite the first and connected with it by a bridge over the river. Aethelstan, the successor of Edward the Elder, established a royal mint there. In 1013 the town submitted to Sweyn. William I. erected a castle, and mention of a new borough occurs in Domesday Book, and this seems to be the first evidence of the existence of the "French borough" which grew up in Nottingham under the Normans, and was distinguished from the English borough by the different customs which prevailed in it. Parliaments were held at Nottingham in 1334, 1337 and 1357, and it was the scene of the conference of the judges with Richard II. in August 1387. David II. of Scotland was imprisoned in the castle. Edward IV. assembled his troops at Nottingham in 1461; and it was the headquarters of Richard III. before the battle of Bosworth in 1485. In 1642 Charles I. finally broke with the Parliament by setting up his standard at Nottingham, and during the ensuing Civil War the castle was held by each of the two parties more than once. In 1644 it was dismantled by Cromwell's orders.

The first charter (Henry II.) confirmed to the burgesses the

liberties they had under Henry I., referred to a market on Saturdays, and forbade the working of dyed cloth, except in Nottingham, within ten leagues of the borough. John confirmed this and granted a gild-merchant. Henry III. allowed the burgesses to hold the town in fee-farm, and Edward I. granted them a mayor and two bailiffs, one to be chosen from each borough. Henry VI. confirmed all preceding privileges, first incorporated the mayor and burgesses, and granted that the town, except the castle and gaol, should be a county of itself. Two sheriffs were to replace the two bailiffs. This charter remained, except for temporary surrenders under Charles II. and James II., the governing charter of the corporation until the Municipal act of 1835. Nottingham returned two members to parliament from 1295 until 1885, when the number was increased to three, and again to four in 1918. Edward I. granted an eight-days' fair in September and a fifteen-days' fair in November, the last altered by Richard II. to a five-days' fair in February. Two other fairs were granted by Anne; one large fair, Goose fair, is still held. This begins on the first Thursday in October and lasts three days. The markets on Wednesdays and Saturdays are held by prescriptive right. Besides the Reform riots of 1831, Nottingham witnessed in 1811 the Luddite disturbances. In 1870 Nottingham was made the seat of a suffragan bishop of the diocese of Lincoln, but as it is now in the diocese of Southwell there is no suffragan bishopric. In 1921 the Elizabethan Wollaton hall was bought from Lord Middleton by the corporation.

Nottingham stands on the Trent and Leen, 125 m. N.N.W. of London by the L.M.S.R.; it is also served by the L.N.E.R. Water communications are afforded by the Grantham canal, the Nottingham and Erewash canals, communicating with the Cromford canal in Derbyshire, and by the Trent. A railway line to Mansfield was opened in 1917, giving access to the docks at Immingham. The plan of the town is irregular and in the centre is an open market place $5\frac{1}{2}$ ac. in area. Nottingham castle occupies a fine site to the south, on an abrupt rocky hill. The ancient remains include a restored Norman gateway and fragments of the fortifications. In 1878 the site was acquired on lease by the corporation, and the building was opened as the Nottingham and Midland Counties Art museum. The church of St. Mary is a Perpendicular cruciform structure, with a central tower. St. Peter's church is mainly Perpendicular, but shows traces of an earlier building. St. Nicholas' church, near the castle, is a plain building of brick dating from 1676.

The University college, opened in 1881, contains the free municipal library. The museum of natural history was transferred from the University college to Carltonrood in 1920. New buildings have been built for the University college by Sir Jesse Boot, on the west side of the town, on a site of 220 ac. called Highfields. The free grammar school, founded in 1513, for some time in disuse, was revived in 1807, and on its removal in 1868 to new buildings, became known as the High school. There are also the Nottingham High school for girls; the blue-coat school, founded in 1723; and the Nottingham school of art, for which a fine building was erected in 1865 in the Italian style. The Midland Baptist college was transferred from Chilwell to Nottingham in 1882.

The General hospital was founded in 1781. The Arboretum and the Forest are the principal public pleasure-grounds; the county cricket club plays matches on the Trent Bridge ground, and there is a racecourse at Colwick, east of the city. To the north-west, but within the city boundaries, are the industrial districts of Radford and Basford, beyond which lies Bulwell, with collieries, limestone quarries and earthenware manufactories. Bestwood park, in the vicinity, contained a hunting lodge of Henry I., being included in Sherwood forest. To the north, Sherwood is a growing residential district; another extends towards Gedling on the east. Southward, across the Trent, West Bridgford is another large residential suburb. To the west is Lenton, and Beeston has become a populous suburb mainly owing to the establishment of large cycle and motor works.

Nottingham itself became an important seat of the stocking trade towards the close of the 18th century. It was here that

Richard Arkwright in 1769 erected his first spinning frame, and here James Hargreaves had the year previously removed with his spinning jenny, after his machine had been destroyed by a mob at Blackburn. Nottingham has devoted itself chiefly to cotton, silk and merino hosiery. Up to 1815 point lace was also an important manufacture. In 1808 and 1809 John Heathcoat obtained patents for machines for making bobbin net, which inaugurated a new era in the lace manufacture. The industries also include bleaching, the dyeing, spinning and twisting of silk, the spinning of cotton and woollen yarn, hosiery and drugs; the leather industry has grown considerably, and manufacture of boots and shoes, furniture making, rubber manufacture, engineering and brewing, cycle works and tobacco factories are important, and the industries, especially the iron and steel and manufacture of machinery, have the advantage of the close proximity of coal-mines. There is a large cattle market.

Nottingham was created a city and county of a city by letters patent 1897. The parliamentary borough returns four members to parliament.

NOTTINGHAMSHIRE, a county of England, area 843.4 square miles. The highest land, in places exceeding 600 ft., is found in the west between Nottingham and Mansfield. The hills die away eastward towards the basin of the Trent and Idle. In the Dukeries portions of the Sherwood forest are still preserved.

Early History.—In the limestone caves near Cresswell implements of presumably the Paleolithic age have been found along with remains of the mammoth, cave-lion, rhinoceros, etc., otherwise Nottinghamshire does not seem to have been inhabited until Neolithic times. The chief evidences of settlement in the Neolithic and Bronze ages come from the more open county of the south-east. The town of Nottingham, even in pre-Roman times, seems to have marked the point where the Trent was crossed by the tracks along which salt was distributed from Cheshire and Worcestershire. The presence of river and forest seemed to have caused the Romans to deflect the course of the Fosse Way north-eastward from Leicester via Newark to Lincoln, and so they did not influence the history of the county profoundly. The earliest Teutonic settlers were an Anglian tribe who, not later than the 5th century, advanced from Lincolnshire along the Fosse Way, and settled in the fertile districts of the south and east. At the end of the 6th century Nottinghamshire already existed as organized territory, though its west limit probably extended no farther than the Saxon relics discovered at Oxtun and Tuxford. Nottingham after the treaty of Wedmore became one of the five Danish boroughs. On the break-up of Mercia, Nottinghamshire was included in the earldom of the Middle English, but in 1049 it again became part of Leofric's earldom of Mercia. The first mention of the shire of Nottingham occurs in 1016, when it was harried by Canute. The boundaries have remained practically unaltered since the time of the Domesday Survey.

The most interesting historic figure in the Domesday Survey of Nottinghamshire is William Peverel. His fief represents the honour of Nottingham, and in 1068 he was appointed constable of the castle which William the Conqueror had raised at Nottingham. The chief lay tenant was Roger de Busli, while the majority of the church lands belonged to the archbishop of York. The Cliftons of Clifton and the Byrons of Newstead held lands in Nottinghamshire at the time of the Survey. Holme Pierrepont belonged to the Pierreponts from the time of Edward I.; Shelford was the seat of the Stanhopes, and Langer of the Tibetots, afterwards earls of Worcester. Archbishop Cranmer was a descendant of the Cranmers of Aslockton near Bingham. Of the old castles the principal remains are those at Newark, but there are several old mansions, as at Kingshaugh, Scrooby, Shelford, Southwell, Wollaton Hall, near Nottingham (c. 1580). The more modern mansions are Welbeck and others in the Dukeries (*q.v.*). Nottinghamshire was originally included in the diocese and province of York, and in 1291 formed an archdeaconry. After the Conquest several monastic establishments were founded, and at the dissolution of the monasteries there were no fewer than 40 religious houses. The only important monastic remains, however, are those at Newstead.

Until 1568 Nottinghamshire was united with Derbyshire under one sheriff, the courts and tourns being held at Nottingham until the reign of Henry III., when with the assizes for both counties they were removed to Derby. In the time of Edward I., the assizes were again held at Nottingham, where they are held at the present day. The Peverel Court, founded before 1113 for the recovery of small debts, had jurisdiction over 127 towns in Nottinghamshire, and was held at Nottingham until 1321, in 1330 at Algarthorpe and in 1790 at Lenton, being abolished in 1849.

In the Wars of the Roses the county as a whole favoured the Yorkist cause, Nottingham being one of the most useful stations of Edward IV. In the Civil War of the 17th century most of the nobility favoured the Royalist cause, but Nottingham Castle was garrisoned for the parliament, and in 1651 was ordered to be demolished.

Industries.—The malting and woollen industries flourished in Norman times. The latter declined in the 16th century, and was superseded by the hosiery manufacture which sprang up after the invention of the stocking-loom in 1589. The smiths of Nottingham were also famous in the middle ages, smelting the ore with charcoal from Sherwood. The earliest evidence of the working of the Nottinghamshire coalfield is in 1259, when Queen Eleanor was unable to remain on account of the smoke of the sea-coal. In 1881, 39 collieries were at work in the county. Hops were formerly grown, and Worksop was famous for its liquorice. Numerous cotton-mills were erected in Nottinghamshire in the 18th century, and there were silk-mills at Nottingham. The manufacture of tambour lace existed in the 18th century, and was facilitated in the 19th century by the manufacture of machine-made net. Now-a-days coal is mined chiefly around Nottingham, Mansfield and Worksop. Clay, sandstone and limestone are also extensively raised. Nottingham is the principal centre of the lace and hosiery industries. There are silk, worsted and cotton mills. A large number of hands are employed in machinery works, and cycle and motor manufactures are important. The manufacture of tobacco is considerable at Nottingham and Hucknall Torkard.

In 1926, 426,966 ac. were under crops and grass, the most fertile land lying on the alluvium along the Trent. The chief grain crops are wheat and oats, with barley covering about half as great an acreage. Root crops and potatoes also take up a large acreage, while there were 18,602 ac. of clover and rotation grasses for hay. Beans occupied 6,658 and sugar beets 3,231 acres. Apples and pears are grown but there are no large orchards. The shire raises cattle, chiefly shorthorn, and dairying is extensively practised. Sheep are not numerous, the chief breed being Leicesters and various crosses. The old local forest breed is almost extinct.

Communications.—The L.M.S.R. and L.N.E.R. serve the county. The Trent is navigable throughout the county and the Idle between Bawtry and the Trent. A few canals centre upon Nottingham. The area of the administrative county is 540,123 ac., with a population (1921) of 641,149. The county contains the city and county and municipal borough of Nottingham and the municipal boroughs of Retford or East Retford, Mansfield and Newark. For parliamentary purposes the county is divided into five divisions (Bassetlaw, Broxtowe, Newark, Rushcliffe and Mansfield), each returning one member; and the parliamentary borough of Nottingham returns one member for each of its four divisions. There is one court of quarter sessions.

Thoresby, 3 vols., London, 1797); Thomas Bailey, *Annals of Nottinghamshire* (4 vols., 1852-56); J. P. Briscoe, *Old Nottinghamshire* (1881); J. Ward, *Descriptive Catalogue of Books relating to Nottinghamshire* (Nottingham, 1892).

NOÜMENON, a philosophical term put into currency by Kant and not much used except in definite reference to his doctrine. In the Kantian system the term "noümena" means things in-themselves as opposed to "phenomena" or things as they appear to us. According to Kant the human mind is such that it can never penetrate by its speculative powers to things-in-themselves, but can only know phenomena. Thus we have the odd position that noümena, or the contents of the intelligible world, are just the things to which thought can never penetrate. The term,

however, is a relic of an early period of Kant's mental development. In his fully mature or critical position he held that the noumenal was inaccessible to the speculative reason, and yet that we are not altogether excluded from it, since the practical reason, *i.e.*, our capacity for acting as moral agents, assures us of the existence of a noumenal world wherein freedom, God and immortality have a real place.

The relation of noumena to phenomena in the Kantian system is a most difficult one; and, in view of the fact that the acutest intellects in Europe have been engaged vainly for more than a century in reconciling the various passages on the subject, the safest conclusion is that they are irreconcilable. The course adopted by Kant's immediate successors in German idealism was to reject the whole conception of noumena, for the reason that what is essentially unknowable has no existence for our intelligence. Kant, however, protested strongly against this development when it was propounded by Fichte, and held that he had concluded it by his "refutation of idealism": he stood unshakably to the belief in an absolutely real world behind phenomena.

Kant's position may be illogical as he himself stated it, but it is the expression of a sound principle: we must connect it with his general tendency to recognize the dynamic side of things. He saw, what so many of his successors failed to see, that the world as we know it is an expression of power; and he could not imagine whence the power could come if not from a world beyond phenomena. (See KANT; PHENOMENA.)

NOVA. A nova may be defined as a variable star which brightens up for a short time to a luminosity far exceeding that of its normal condition, and does so only once over a long interval of time. The facts observed are (1) a very rapid brightening (frequently many thousandfold in two or three days) followed by a slower fluctuating fall in brightness; (2) a steady sequence of changes in the star's spectrum, which in the beginning consists of lines, due to ionized atoms of such elements as calcium, iron and titanium, and finishes with those due to ionized atoms of oxygen, nitrogen and helium; (3) the rapid expansion of a disc round a central bright nucleus, with evidence of complex internal motions.

The first nova which counts in modern astronomy was that of Tycho Brahé, *N Cassiopeiae*, 1572, the first nova definitely allotted not to the solar system but to the stellar universe by measure of its distance. This nova was brighter than Jupiter or Venus, was easily visible at midday, and remained a naked-eye object for 16 months. *N Coronae Borealis*, 1866, was the first nova to be examined through the spectroscope, and its spectrum was found by Sir William Huggins to consist of bright hydrogen lines on a continuous spectrum which also showed many absorption lines. Ten years later Cornu noticed that the bright line spectrum of *N Cygni*, 1876, was very like that of the chromosphere, the layer of the sun's atmosphere which flashes into view just as the disc of the sun passes behind the moon at a total eclipse. This was amply confirmed in the case of later novae, the next point to be noticed being that this spectrum is in general, at discovery, a dark line spectrum; the dark lines are always displaced markedly to the violet, suggesting that the gases which give rise to them are moving rapidly towards the observer.

The majority of novae appear either in the Milky Way, *i.e.*, with galactic latitudes less than 20° , or else in spiral nebulae. In the Milky Way they are concentrated in the direction of the star clouds of *Sagittarius*, in galactic longitude, 320° to 340° , and judging from analogy with the 86 novae discovered mainly by Hubble in the *Andromeda* nebula, this means that the conditions are most favourable for the production of novae in the central regions of the Milky Way and of the spiral nebulae. Many novae settle down again as faint variable stars of about their initial magnitude, showing very little sign if any of the upheaval through which they have passed. The range of magnitude involved in their outbursts may be from 9 to 14 magnitudes, the rate of rise just before maximum varying from 7.6 to 0.2 per diem, the rate of fall, per diem, being from 10 to 50 times as slow. The brightness at maximum is probably about -5.0 absolute magnitude, though values have been found ranging from 0.0 to -15.4 absolute magnitude. In general it may be said that the more

violent the outburst, the greater the contrast between the rates of rise and fall, and the more rapidly the star runs through its spectral changes.

To explain the startlingly high velocities of the out-rushing gases, reaching at times the value of 3,000 km. sec. or $\frac{1}{100}$ the velocity of light, E. A. Milne has advanced the theory that a sudden brightening of a stellar nucleus, with the accompanying increased pressure of radiation, involves the blowing out of the gases of the outer atmosphere of the star with accelerations which might easily lead to limiting velocities of the values found in novae. Atoms just balanced under gravity and radiation pressure are driven outwards by the increase in the radiation pressure; they then absorb light of a shorter wave-length coming from the star and are no longer screened by the intervening layer of atoms which absorb light of the wave-length which has been mainly involved in supporting them before the outburst. A stream or shell of atoms thus driven out gives the dark lines displaced to the violet which are seen by the distant observer. It is possible to explain in terms of Milne's theory many of the miscellaneous complications observed in the multiple dark lines with their varying shifts, but, as special assumptions have to be made for each complication, it is wiser at this stage of our knowledge not to strain the one hypothesis but to wait the ripe time for further simplifications.

It remains to be asked what leads to the sudden brightening of a faint star, which results in the production of the aforementioned phenomena. There are two main lines of explanation available. Newton was one of many enquirers who have looked outside the star for the source of the necessary energy and have postulated collision or the inflow of matter as the exciting cause. Laplace held the view that a great surface conflagration of a star was all that was involved and this view has been held in varying form by many others. The breakdown of equilibrium in a cooling star through chemical combination at low temperature, through radioactive forces, or through unstable pulsations, have all been suggested, as have also tidal eruptions through the close passage of a second star or companion. The latter theory is the bridge to the view that we have a collision between a star and a planet or comet, or even a collision between two stars. The frequency of the phenomenon makes an explanation in terms of the collision of two stars difficult to accept, and Seeliger's view, that what we behold in a nova's outburst is the result of a star (or a binary star) entering into a nebula, seems on the whole the best solution of the problem so far proposed. E. W. Brown has worked out the effect to be observed when a star enters a nebula, and his picture closely resembles what the camera shows at the present time for the region round *N Persei*, 1901—a spherical expanding shell and a fan-like appendage on one side of the star. In the case of this star there was evidence of nebulosity round the star at the time of outburst. It seems then not unlikely that some of the novae are to be explained in terms of Seeliger's hypothesis of an encounter of a star with dark nebulosity. Differences between the behaviour of various novae may well argue against a common cause for the initial brightening of all novae. It is, perhaps, fairest to return an open verdict on the cause for the nova's original brightening, though we can now follow with reasonable certainty the main effects which follow the great outburst of radiation.

See *Handbuch der Astrophysik*, Bd. VI. (1927). (F. J. M. S.)

NOVALICHES, MANUEL PAVIA Y LACY, 1st MARQUIS DE (1814–1896), Spanish marshal, was born at Granada on July 6, 1814. In 1833 lieutenant in the guards of Queen Isabella II., he became general of division during the Carlist war (1833–40). Senator in 1845, war minister in 1847, and marquis in 1848, he went out to Manila in 1852 as captain-general of the Philippine Islands, crushed a formidable insurrection in 1854 and carried out many useful reforms. He commanded the reserves in the Peninsula during the Moroccan war, twice refused the war portfolio offered him by O'Donnell and Narvaez, and when the revolution broke out in September 1868 accepted the command of Queen Isabella's troops. He was defeated by Marshal Serrano at the bridge of Alcolea on September 28, 1868, and was so badly wounded in the face that he remained disfigured for

life. He kept apart during the revolution and went to meet King Alfonso when he landed at Valencia in January 1875. The Restoration made him senator, and King Alfonso gave him the Golden Fleece. He died in Madrid on Oct. 22, 1896.

NOVALIS, pseudonym of Friedrich Leopold, Freiherr von Hardenberg (1772-1801), German poet and novelist, one of the pioneers of the Romantic movement, was born on May 2, 1772, on his father's estate at Oberwiederstedt in Prussian Saxony. He studied philosophy at Jena, and law at Leipzig and Wittenberg. At Tennstedt, near Langensalza, he was betrothed to Sophie von Kühn. He became auditor to the salt works at Weissenfels where he heard (1797) of Sophie's death. He expressed his grief in the beautiful *Hymnen an die Nacht*, in which the religious poetry of the Romantics reaches its greatest height. He then entered the Mining Academy at Freiberg, in Saxony, to study under A. G. Werner, whom he immortalized as the "Master" in *Die Lehrlinge in Saïs*. In the autumn of 1799 he read to the circle of young Romantic poets at Jena his *Geistliche Lieder*. In 1800 he was appointed local magistrate in Thuringia, and after a short illness he died at Weissenfels on March 25, 1801.

His all too short life did not permit him to blend his mystic and philosophical conceptions into a harmonious whole, but his work, fragmentary as it was, and his lovable personality left a strong mark on the Romantic school. Novalis had dreamed of an all-embracing formula which would bring life and poetry, science and religion, in tune with one another. His longest work was the unfinished romance, *Heinrich von Ofterdingen*; its hero's search for the mysterious blue flower is an allegory of the poet's life. More popular, however, are his shorter lyrics, ranging from *Auf grünen Bergen wird geboren der Gott der uns den Himmel bringt*, to the hymn, *So bleib' ich dir doch treu, wenn alle untrenn leiben*.

There are modern editions of the collected works of Novalis by E. Heilborn (3 vols., 1901), and by J. Minor (3 vols., 1907; rep., 1923). His *Briefwechsel* with the Schlegels was edited by J. M. Raich in 1880. See also E. Heilborn, *Friedrich von Hardenberg* (1901); T. Carlyle's essay on "Novalis"; Obenauer, *Novalis Gesammelte Studien* (1925); H. Hesse and Isenburger, *Novalis. Documente seines Lebens und Sterbens* (1925).

NOVARA, town and episcopal see, Piedmont, Italy, capital of the province of Novara, 31 m. by rail W. of Milan, 538 ft. above sea-level. Pop. (1921) 50,965 (town), 56,260 (commune). Till 1839 surrounded by Spanish ramparts, Novara is now an open, modern town. The cathedral, except for the octagonal domed-roofed baptistery (10th century), was rebuilt (1863-65); the church of S. Gaudenzio, dedicated to Bishop Gaudentius (d. 417), who is buried under the high altar, rebuilt by Pellegrino Tibaldi about 1570, has a baroque campanile and a dome (1875-78) 396 ft. high. The two first contain pictures by Gaudenzio Ferrari, a native of the town. The city also contains handsome market buildings erected in 1817-1842, a large hospital dating from the 9th century and a court-house constructed in 1346. The town has also a museum of Roman antiquities. The principal industry is the carding and spinning of silk; there are also iron-works and foundries, cotton mills, rice-husking mills, organ factories, dye-works, printing and map-making works.

Novara, the ancient *Novaria*, lay on the road between Vercellae and Mediolanum. Its rectangular plan probably survives from Roman days. A dukedom of Novara was constituted by the Lombards, a countship by Charlemagne. In the 12th century it accepted the protection of Milan. In 1706 it was occupied by Savoy troops. At the Peace of Utrecht it passed to Austria with Milan; but was granted to Charles Emmanuel in 1735. Under the French it was the chief town of the department of Agogna. Restored to Savoy in 1814, it was in 1821 the scene of the defeat of the Piedmontese by the Austrians, and in 1849 of the more disastrous battle which led to the abdication of Charles Albert and an Austrian occupation of the city. Peter Lombard and Dolcino (see APOSTOLICI) were natives of Novara.

In the church of San Pietro del Rosario was pronounced the papal anathema against the followers of Fra Dolcino.

NOVARA was the scene of a battle on March 23, 1849, between the Austrians, 70,000 strong with 182 guns, under Radetsky and King Charles Albert, who led the Sardinian forces, 65,000 men

with 140 guns. Chzarnowski, a Pole, virtually directed the army. Armistice, concluded Aug. 9, 1848, was to terminate March 20. Radetsky retreated from Milan on March 17, feigning to retire to Lodi-Cremona, but on reaching San Angiolo he made for Pavia, crossing the Ticino on March 20. Meanwhile Chzarnowski marched on Magenta without encountering the enemy, but here news reached him that the Austrians, whom he had believed were retiring beyond the river Adda, were already at Pavia; thereupon he halted the army and turned it back to Vigevano. Radetsky had advanced so swiftly that Ramorino's Sardinian division south of the Po was cut off, the bridge at Mezzano Corte being destroyed, though it had orders to stand at Cava, threatening the hostile advance. Fighting took place at Mortara on March 21, the Sardinians falling back on Novara, where Chzarnowski decided to await Radetsky. The Austrian leader received a false report that there was only a rearguard at Novara, the main hostile force being at Vercelli. Radetsky moved with his troops on Vercelli, sending the II. Corps on Novara. On approaching this town the II. Corps, March 23, was confronted by the whole Sardinian army, drawn up in a strong position. Fighting began at 11 A.M., and for hours it had to contend against serious odds, showing great tenacity against hostile attacks. At 4 o'clock, Radetsky having recalled the III. Corps, sent it to its assistance, shortly followed by the Reserve Corps. Two hours later the IV. Corps, hearing the sound of guns, came on the scene, threatening the Sardinian right wing and rear by the Vercelli-Novara road, cutting off their retreat. Radetsky now ordered a general advance, and the Sardinians were swept off the Vercelli road, retreating hastily to Novara from all points. Numerous bodies deserted during the night and confusion was general. Charles Albert abdicated that night. His son, Victor Emanuel, the new sovereign, concluded an armistice with Radetsky, the Sardinians escaping a surrender, which would have been inevitable; thereupon the Austrian advance on Turin came abruptly to a close.

NOVA SCOTIA, a province of the Dominion of Canada, lying between 43° 25' and 47° N. and 59° 40' and 66° 25' W., and composed of the peninsula proper and the adjoining island of Cape Breton (q.v.), which is separated from the mainland by the Strait of Canso. The extreme length from south-west to north-east is 376 m. (N.S. 268, C.B. 108); breadth 60 to 100 m.; area 21,428 sq. miles. The isthmus of Chignecto, 11½ m. wide, connects it with the province of New Brunswick.

Geology and Physical Features.—Nova Scotia may be described as an ancient mountain land almost completely worn down. The original folds apparently ran either east or north-east and were complicated by intrusive granite in the country south-west of Halifax. The fact that some Carboniferous beds, at any rate, transgress upon the worn folds, indicates that the folding is either Carboniferous or earlier in date. The general disposition of the folds seems to be indicated in the coast-line and in the lines of higher land, which, however, rarely reach above the 1,000 ft. level, save in the Cobequid mountains, which rise to a few feet above this figure. They occupy the neck between New Brunswick and Nova Scotia, and represent the axis of a fold. The Chignecto bay to the north-west, and the Minas basin and Cobequid bay to the south, indicate by their directions the divergence of the old worn folds of Nova Scotia on the one hand, and of St. John, New Brunswick, on the other. Around the south-east of the Bay of Fundy are horizontal Triassic deposits including volcanic elements, which give rise to a precipitous coast from Brier island to Cape Split. The western railway of Nova Scotia runs on low ground between this structural feature and the main mountain fold-axis farther south-east. This feature is broken at Digby Gut, and a portion of the lowland within it is submerged as the long Annapolis basin (called the garden of Nova Scotia).

One of the last geological changes has been a land-sinking, which has given rise to the remarkable succession of cliff-fringed rias; with islands offset along the Atlantic coast, Halifax harbour being the most famous of these. The north shore is, as a rule, low, and Pictou has its chief harbour.

Cape Breton island is essentially a continuation across the

narrow strait of Canso. The granitic south-west is rugged and barren, with many small lakes and peat bogs. The coasts of the province are famous for its tides. Though they rarely exceed 8ft. at Halifax, they are said to average 42-3ft. in the Bay of Fundy, and, at the top of the funnel in Cobequid bay, they even reach 53 feet.

Climate.—The maritime influences are more marked in this province than in New Brunswick (*q.v.*). The average rainfall is between 40 and 45in., except along the southern coast-line, where it is nearly roin. greater. The winter snowfall is slight. At Yarmouth, in the extreme south-west, the temperature ranges from 25.4° (February) to 60-70 (July).

Area and Population.—The area of the province is 21,428 sq.m., of which 21,068 are land area and 360 water area. The population (1921) was 523,837. In 1871 it was 387,800, the percentage increase over the 50 years being 35.08%. The increase was most marked in the decade 1871-1881. The great mass of the people are of British descent, but in parts of Cape Breton are found descendants of the early French settlers; in Lunenburg and the south-east is a large German colony; near Halifax are a number of negroes from the West Indies, and scattered through the province are a few Micmac Indians. Few are of absolutely pure Indian blood. The settlers of English and Scottish descent are about equal in numbers, but the latter have been more prominent in the development of the province. The Irish are found chiefly in Halifax and in the mining towns of Cape Breton. Roman Catholics, Presbyterians and Baptists predominate, though the Church of England is strong in Halifax, as in most administrative centres.

Administration.—The executive authority is in the hands of a lieutenant-governor, appointed for five years by the Federal Government, and of a council appointed from and responsible to the local legislature. This consists of a lower house of assembly, and of a legislative council of 20 life members, which the assembly has frequently, but in vain, endeavoured to abolish. The municipal system was introduced subsequent to federation on July 1, 1867. Nova Scotia and Quebec possess a legislative council as well as a legislative assembly.

The revenue is chiefly made up of the Dominion subsidy and of royalties on mining concessions, chiefly those on coal and other special taxes. The province is represented in the Dominion senate by ten members and in the House of Commons by 14 (1926).

Education.—Primary education is free and compulsory, and undenominational; secondary education is also free, but optional. There are also many private schools under denominational control. Besides the elementary high schools and academies there are four universities: King's college, Windsor (Anglican), founded in 1790; Acadia university, Wolfville (Baptist, 1839); St. Francis Xavier, Antigonish (Roman Catholic, 1866); and Dalhousie university, Halifax (undenominational), established by charter in 1818, reorganized in 1863, the largest possessing faculties of arts, science, medicine and law.

Commerce and Manufactures.—Nova Scotia is naturally a sea-going province, and till about 1881 had the largest tonnage, in proportion to population, in the world. Halifax is still one of the chief winter ports of the Dominion, and Sydney is also a favourite port of call for steamers in need of "bunker" coal. The water-power provided by the rivers supports many manufactures. Several sugar-refineries exist, and a large trade is carried on with Bermuda and the West India islands.

The fisheries of Nova Scotia are the next most important in Canada, after those of British Columbia. Lobsters, cod and mackerel, herring and haddock, constitute the bulk of the catch. Many boats are also fitted out in Lunenburg, Digby, Yarmouth and other ports for the Grand Banks of Newfoundland. A large number are employed in the lobster canneries and other kindred industries. Trout and salmon abound in the inland lakes and streams.

Lumber.—Lumbering was long the chief industry of the province, and is still very important, though the forest left uncut is only some 12,000 sq.miles. The network of small lakes and rivers enables the logs to be brought to the mills with great ease, and

little rough timber is now exported. The chief trees include spruce, fir, pine, birch, oak and maple. The manufacture of wood-pulp for paper is also carried on.

Minerals.—Bituminous coal is mined in various parts of Cape Breton (*q.v.*) and in the counties of Cumberland and Pictou. The seams dip at a low angle, and are of great thickness, especially in Pictou county. The known coal-fields cover some 1,000 sq.miles. Other important centres are Springhill, Acadia Mines, Stellarton and Glace Bay (C.B.). It is shipped as far west as Montreal, and to the New England States. The by-product industries are very important. Iron is largely produced, chiefly in the vicinity of the Cumberland and Pictou coal-fields. The deposits include magnetite, red haematite, specular, limonite and carbonate ores. Blast furnaces are in operation, especially at New Glasgow, Sydney and North Sydney, though most of the ore used at Sydney is imported from Newfoundland. The quarries of easily worked limestone, the product of which is used as a "flux" in the blast furnaces, add to the value of the iron deposits. Gold occurs in workable quantities in the quartz all along the Atlantic coast, and several small but successful mining enterprises are in operation. Large deposits of gypsum occur, especially at Windsor, in Hants county. Manganese and copper are also worked on a small scale.

Agriculture.—The attention paid to lumbering, fishing and shipping, and the subsequent emigration westwards have lessened the importance of this industry. Mixed farming is, however, largely carried on, and of late years dairy farming has been greatly extended and improved, and much butter and cheese is exported to England. Both the Dominion and the Provincial Governments have endeavoured to introduce scientific methods. Nova Scotia is specially famous for its fruits, the export of apples being the main feature. The centre of this industry is the valley of the Annapolis. At the head of the Bay of Fundy and on Minas basin the low-lying meadows produce splendid crops of hay and good pasture, while the cool climate and abundant moisture make the region well suited for dairy farming and stock raising.

Communications.—The country is covered by a network of railways, with a total length of 1,451 miles. The roads are good and cover some 18,000 miles. Telegraph and telephone lines extend all over the province, with cable stations at Canso and Sydney. There are Government owned and commercial radio stations at Halifax, Seal island and Sambro outer Bank light-ship; direction-finding stations at Canso, Chebucto, St. Paul island and Yarmouth; and three licensed public commercial stations at Louisburg.

History.—Nova Scotia may well have been the Markland of early Norse and Icelandic voyages, and Cape Breton was visited by the Cabots in 1497-98, but not till 1604 was any attempt at permanent colonization made by Europeans. In that year an expedition was headed by a Frenchman, Pierre de Guast, Sieur de Monts (1560-c. 1630), who had received from Henry IV. full powers to explore and take possession of all lands in North America lying between the 40th and 46th parallels of north latitude. De Monts and his friend de Poutrincourt (d. 1615), endeavoured to form settlements at Port Royal (now Annapolis), St. Croix (in New Brunswick) and elsewhere, but quarrels broke out with the Jesuits, and in 1613 the English colonists of Virginia invaded the settlement and expelled the greater part of the inhabitants. In 1621 Sir William Alexander obtained from James I. a grant of the whole peninsula, which was named in the patent, "Nova Scotia, instead of Acadia, the old name given to the colony, by the French. During the reign of Charles I. the still existing order of baronets of Nova Scotia was instituted, and their patents ratified in parliament. The Treaty of St. Germain-en-Laye (1632) confirmed France in the possession of Acadia, Cape Breton and New France; but fierce feuds broke out among the French settlers, and in 1654 a force sent out by Cromwell took possession of the country, but

by the Treaty of Breda (1667) it was restored to France by Charles II. Continual fighting went on between the French and the British colonists of New England, the Indians taking part, usually on the side of the French; in 1710 the province was finally captured by Great Britain and ceded to her in 1713 by the Treaty of Utrecht, under the name of "Acadia or Nova Scotia," the French remaining masters of Cape Breton. In 1749 Halifax was founded as a counterpoise to Louisbourg in Cape Breton, and over 4,000 colonists sent out. In 1769 Prince Edward island (formerly Isle St. Jean) was made a separate government. An influx of American Loyalists led in 1784 to the erection of New Brunswick into a separate colony.

During the wars of the American and French revolutions Halifax grew apace. Between 1784 and 1828, a large Scottish emigration, chiefly from the Highlands, had settled in the counties around Pictou, and the lumbering industry rose to great proportions. Agriculture was for some time neglected, but in 1818 the letters of "Agricola" (John Young, 1773-1837) gave it an impetus. Representative institutions had been granted as early as 1758, but power long rested mainly in the hands of a Council of Twelve, comprising the chief justice, the Anglican bishop and other high officials. In 1848, after a long struggle, responsible government was won by the legislature, led by Joseph Howe.

In these political struggles, education was often the battleground, the fight ending in 1864 in the establishment of free primary and secondary schools by Dr. (afterwards Sir Charles) Tupper, and the re-organization on an undenominational basis of Dalhousie university. (See HALIFAX.) In 1867 the province entered the new Dominion of Canada. For some years afterwards an agitation in favour of repeal was maintained, but it has died away.

After several previous attempts, an effort was made in 1926 to abolish the second chamber (or legislative council), the premier, the Hon. E. N. Rhodes, suggesting that the members of the legislative council should vote themselves out of office. This was declined, and the opinion of the judicial committee of the Privy Council in England was sought on the competence of the lieutenant-governor either to dismiss members of the upper house or to increase their numbers above 21 by Order in Council. On Oct. 19, 1927, it was determined that the lieutenant-governor had power to appoint any number of members to the legislative council, such members being appointed "during the pleasure of His Majesty represented in that behalf by the lieutenant-governor acting by and with the advice of the executive council." The Government thereupon proceeded in its determination to abolish the house. Some members of the upper chamber were dismissed and 13 new members were appointed, with the result that on Feb. 29, 1928, the bill for its own abolition was passed by the upper chamber of the Nova Scotia legislature.

NOVATIANUS, Roman presbyter, and one of the earliest antipopes, founder of the sect of the Novatiani or Novatians, was born about the beginning of the 3rd century. On the authority of Philostorgius (*H.E.* viii. 15) he has been called a native of Phrygia. He was ordained at Rome by Fabian, or perhaps by an earlier bishop; and during the Decian persecution he maintained the view which excluded from ecclesiastical communion all those (lapsi) who after baptism had sacrificed to idols—a view which had frequently found expression, and had caused the schism of Hippolytus. Bishop Fabian suffered martyrdom in January 250, and, when Cornelius was elected his successor in March or April 251, Novatian objected on account of his known laxity on the above-mentioned point of discipline, and allowed himself to be consecrated bishop by the minority who shared his views. He and his followers were excommunicated by the synod held at Rome in October of the same year. He is said by Socrates (*H.E.* iv. 28)

to have suffered martyrdom under Valerian. After his death the Novatians spread rapidly over the empire; they called themselves *καθαρῶν*, or Puritans, and rebaptized their converts from the Catholic view. The eighth canon of the council of Nice provides in a liberal spirit for the readmission of the clergy of the *καθαρῶν* to the Catholic Church, and the sect finally disappeared some two centuries after its origin. Novatian has been confounded with Novatus, a Carthaginian presbyter, who held similar views.

Novatian was the first Roman Christian who wrote to any considerable extent in Latin. Of his numerous writings three are extant: (1) a letter written in the name of the Roman clergy to Cyprian in 250; (2) a treatise in thirty-one chapters, *De trinitate*; (3) a letter written at the request of the Roman laity, *De cibis judaïcis*. They are well-arranged compositions, written in an elegant and vigorous style. The best editions are by Welchman (Oxford, 1724) and by Jackson (London, 1728); they are translated in vol. ii. of Cyprian's works in the *Ante-Nicene Theol. Libr.* (Edinburgh, 1869). The Novatian controversy can be advantageously studied in the *Epistles* of Cyprian.

NOVATION, a legal term derived from the Roman law, in which *novatio* was of three kinds—substitution of a new debtor, of a new creditor, or a new contract. In English law the term (though it occurs as early as Bracton) is scarcely naturalized; substitution of a new debtor or creditor being generally called an assignment. A new contract either tacitly or expressly operates as a release from the original contract. Where the substituted contract is one of a higher nature, as where a contract under seal supersedes a simple contract, it is called a merger. The extinction of the previous contract is held to be sufficient consideration. The particular points on which novation turns are whether the new firm or company has assumed the liability of the old, and whether the creditor has consented to accept the liability of the new debtors and discharge the old. The question is one of fact in each case. (See especially the Life Assurance Companies' Act, 1872, s. 7, where the word, "novations" occurs in the marginal note to the section, and so has quasi-statutory sanction.) Scots law seems to be more stringent than English law in the application of the doctrine of novation, and to need stronger evidence of the creditor's consent to the transfer of liability. In American law, as in English, the term is something of a novelty. In Louisiana, and generally in systems much influenced by Roman law, novation forms a more specific department of the law of contract (*q.v.*).

NOVAYA ZEMLYA. An Arctic land off the coast of European Russia, to which it belongs, consists of two large islands separated by a narrow winding channel 56 m. long, the Matochkin Shar. It lies between 70° 31' and 77° N., and between 51° 35' and 69° 2' E. and forms an elongated crescent, being nearly 600 m. long with a width of 30 to 90 m., and an area of about 30,000 sq. miles. It separates the Barents sea on the west from the Kara sea on the east. With Vaigach island 30 m. to the south, and the mainland, Novaya Zemlya forms a continuation of the Pai-Khoi hills, a branch of the Ural folds.

The greatest heights occur in the neck of the south islands where near Matochkin Shar are altitudes of about 4,000 ft. In the middle part of the south island there are few elevations over 1,400 ft., but in the south the summits rise to over 2,000 ft. The north island seldom rises to greater altitudes than 3,000 ft.

Geology.—A central zone of upper Cambrian and Devonian rocks extends along the islands. These quartzites, conglomerates and dolomites are flanked by carboniferous shales and limestones. The minerals of value are some lignite and a little copper ore.

Climate.—Novaya Zemlya is colder than Spitsbergen (which lies more to the north) as in some degree it shares in the continental conditions of northern Russia and Siberia. The middle and northern parts of the west coast are not so cold as the east. Temperatures at Karmakul are 2.3° F (Feb.) and 43.2° (July). Snow is universal from October to May.

Flora and Fauna.—Vegetation is solely tundra and decreases from south to north. It is most luxuriant in Gooseland on the south-west. There are no trees or bushes. The flowering plants number 187.

In the ice-free areas there are foxes, lemmings, bears, reindeer and an occasional wolf. Insects are numerous near the coast. Countless birds come from the south for the breeding season, and at certain parts of the sea-coast the rocks are covered with

millions of guillemots, while great flocks of ducks of various sorts, geese and swans swarm every summer on the valleys and lakes of the south. Whales, walruses and various seals are frequently seen. The goltzy occurs in the rivers.

The numbers of sea mammals and birds attracted Russian hunters, and even in the 16th century they had extended their huts (stanovishtcha) to the extreme north of the island. Many of them wintered for years on Novaya Zemlya. Owing to the ice in the White sea Russian hunters found Novaya Zemlya less easy of access than did the Norwegians. But about 1877 systematic attempts at settlement were begun by the Russian Government, several families of Samoyedes being established at stations on the west coast of the south island, including Karmakul on Moller bay, Pomorskaya bay and Byeloshya bay. There is a Russian observatory on Matochkin Shar.

History.—Novaya Zemlya was probably known to Novgorod hunters in the 11th century and to Norse hunters a century earlier. In 1553 Sir Hugh Willoughby may have sighted Goose-land. In 1556 Stephen Borough reached the south extremity of the Novaya Zemlya, being the first western European to do so. William Barents touched the island (1594) at Sukhoi Nos (73° 46') and followed the coast north to the Orange islands and south to the Kostin Shar. In 1596, after his discovery of Spitsbergen, Barents wintered at Ice haven in 76° 12' N. (see ARCTIC REGIONS). Rumours of silver ore led the Russian Government to send out expeditions. In 1760 Savva Loshkin cruised along the east coast, spent two winters there, and in the next year returned along the west coast, thus accomplishing the first circumnavigation; but the records of his voyage have been lost. In 1768 Lieut. Rozmyslov explored Matochkin Shar, where he spent the winter. The first scientific information about the island is due to the expeditions (1821–24) of Lütke (1797–1882) after whom part of the north island is named Lütkeland. Nearly all the west coast as far as Cape Nassau, as well as Matochkin Shar, was mapped, and valuable scientific information obtained. In 1832 and 1835 Lieut. Pakhtusov mapped the east coast as far as 74° 24'. The work of Karl von Baer in 1837 was untrustworthy. In 1870 the Norwegian, Capt. L. E. H. Johannessen, accomplished the second circumnavigation of Novaya Zemlya and in 1871 E. Carlsen found Barents's winter hut. In 1878 M. Grinevetskiy crossed the south island. Among later expeditions may be mentioned those of C. Nossilov (1887–92), T. N. Chernychev (1895), who made a crossing of the S. island, H. J. Pearson (1895 and 1897), A. A. Borisov (1899 and 1900), O. Ekstam (1900 and 1903), W. Rusanov (1908), who crossed the south of the island, Pavlov and Weise (1912) of the Sedov expedition, who crossed the north island (see ARCTIC), as did O. Holtedahl (1921). P. V. Vittenburg explored the south island in 1925.

(R. N. R. B.)

NOVEL, the name given in literature to a sustained story which is not historically true, but might very easily be so. The novel has been made the vehicle for satire, for instruction, for political or religious exhortation, for technical information; but these are side issues. Its plain and direct purpose is to amuse by a succession of scenes painted from nature, and by a thread of emotional narrative. It was not until the 18th century that it began to be a prominent factor in literary life, and not until the 19th that it took a place in it which was absolutely predominant.

It was Voltaire, in his *Pyrrhonisme de l'histoire*, who set the fashion of calling the *Cyropaedia* a novel, but it is probable that Xenophon had a purpose that was didactic and historical rather than imaginative. The vogue of the novel really began in Alexandrian times, when social life was so far settled in tradition that the pleasure of reflecting on reality had definitely set in. In the 2nd century B.C. a certain Aristides wrote, in six books, the *Milesiaka*, which was probably the beginning of the modern

novel. These Tales of Miletus, the town in which Aristides lived, are lost, but from existing imitations of them in Greek and Latin we can gather that they consisted of humorous and sarcastic episodes of contemporary life. There seems to be good evidence that the bulk of these novelettes, and of the tales which followed them, dealt mainly with the adventures of lovers. In the 2nd century A.D. Lucian preserved for us invaluable pictures of the life in which he moved: his *Lucius or the Ass* and his *True History* are fantastic and extraordinary fictions in which the nature of the novel is not infrequently approached. But a Syrian Christian, Heliodorus, bishop of Tricca in the 4th century, may claim to have come much closer to it in his *Aethiopica*, which has the unique merit of being a perfectly pure love story, in which the marvellous is not absolutely banished, but in which on the whole the solid structure of experience is preserved. In the 6th century, as is supposed, a Greek who is called Longus, but of whose life nothing is known, wrote the voluptuous pastoral story of *Daphnis and Chloë*, which is far superior to all other remnants of Greek fiction which have come down to us, and is the only one of them which can strictly be called a novel. In Latin literature, the *Golden Ass* of Apuleius is manifestly a translation of a lost Greek book, to which Lucian also was indebted. If the *Satyricon* of Petronius was not an isolated phenomenon—and it is highly improbable that this was the case—then the Romans of the Neronian epoch understood to the full the secret of how to produce in prose a satirical, not to say cynical, study of manners in fiction. The *Satyricon* is not less skilfully managed than such later novels as *Gil Blas* or *Peregrine Pickle*, and it is of the same class. From the extent of the principal episode which has been preserved, it is supposed that this novel was not a short tale of intrigue, but was a sustained record, drawn up with careful and lengthy observation of manners, for the single purpose of entertainment. Unfortunately this extraordinary work remains not merely solitary in its class, but itself a fragment. In early Christian times, such books as *The Shepherd of Hermas*, and the productions of Palladius and of Synesius, testified to a certain appetite for prose fiction.

Italy.—It is from northern Italy that the novel of modern Europe (both the literary type and the name) derives. An early collection of tales, called *Il Novellino* or *Cento novelle antiche* (although only 66 of the 100 survive), was composed at the end of the 13th century, and started this class of literature in Europe. These anonymous stories are of extraordinary diversity, chivalrous, mythological, moral and scandalous. The mediaeval view of women and priests and peasants is found in its full development, and there is something of the realistic reflection of customs which was to flourish later in a whole class of fiction. The earliest Italian novelist whose name is connected with his writings is Francesco da Barberino (1264–1348), whose *Documenti d'Amor* was first printed in 1640. He was followed by Giovanni Boccaccio, who wrote his *Filocolo* about 1339 and the *Decameron* some nine years later. Of his disciples the most eminent was Francesco Sacchetti (1335–1400), a Florentine. Sacchetti's *Trecente novelle*, which remained in ms. until the 18th century (1724), are ironical and realistic studies of the life around him in Tuscany. To Giovanni Fiorentino is attributed a collection of 50 tales, called *Il Pecorone*, printed first in 1558, but written in 1378. A great name in the evolution of European fiction is that of Tomaso Guardato, called Masuccio (1415?–1477?); he was a native of Salerno, and was the first of the south Italian novelists. Masuccio imitated no one; his conceptions and his observations are wholly his own. His *Novellino*, printed at Naples in 1476, is divided into five books, each containing ten stories. These deal satirically with the three favourite subjects of the age—namely, jealous husbands, unfaithful wives and debauched priests. He was followed in this, as well as in his vivacity, by Antonio Cornazzano (1431?–1500?), an inhabitant of Piacenza, who wrote Italian with much greater purity than Masuccio, but less vigour. His stories were frequently reprinted, under the title of *Proverbi*. Of the novels of Giovanni Brevio (1480?–1562?) only five have been preserved, but these are of unusual merit. We then reach Matteo Bandello (1480–1561), long the most famous of all the Italian

novelists, whose *Novelle*, first issued in 1554, were eagerly read in all parts of Europe; they are 214 in number. After Bandello the decline of the Italian *novella* is evident. Francesco Maria Molza (1489-1544), whose stories appeared in 1547, was a rival to Bandello, and has been preferred to him by several modern critics. The *Ragionamenti d'Amor* (1548) of Agnolo Firenzuola (1493-1545) was the work of a poet writing in richly embroidered prose. After Firenzuola the great school of Italian story-tellers declined. There was no more novel writing of any importance in Italy until the close of the 18th century, when an admiring study of German literature produced the romances of Alessandro Verri (1741-1816) and Ugo Foscolo (1778-1827). The first Italian novelist of merit in recent times, however, is Alessandro Manzoni (1785-1873), whose *I Promessi Sposi* (1825) enjoyed an unbounded popularity. Manzoni had imitators, but no rivals. In the fourth quarter of the 19th century Italy produced some brilliant and original novelists, in particular Giovanni Verga (1840-1922), Matilda Serao (1856-1927) and Gabriele d'Annunzio (b. 1863).

France.—It was not until about 1450 that the anonymous *Quinze joies du mariage* showed the French to be influenced by the Italian discovery of the novelette of manners. The author of this extraordinary work was perhaps Antoine de la Sale who seems certainly to have written the whole of the *Cent nouvelles nouvelles*, imitated from Boccaccio and Sacchetti. This bud of realistic fiction, however, was immediately nipped by the romances of chivalry, of Spanish extraction, which were only destroyed by the vogue of *Don Quixote*. The translation of Montalvo's celebrated *Amadis de Gaula* enjoyed at this time an extraordinary popularity.

The habit of telling tales freely in prose was not, however, formed in France until after 1500. Bonaventure Despériers (d. 1544) was the author of the *Cymbalum mundi* and of *Nouvelles récréations*, mordant satires and gay stories. Probably to this age also belongs the semi-fabulous Béroalde de Verville, who is supposed to be the author of a collection of facetious anecdotes and conversations, *Le Moyen de Parvenir*. These and other experiments in fiction lead us up to Rabelais, whose magnificent genius adopted as its mode of address the chain of burlesque prose narratives which we possess in *Gargantua* and *Pantagruel*, but his influence on the novel is insignificant. It was half a century later that, in the romantic pastoral of *Astrée*, published in 1610, France may be said to have achieved her first attempt at a novel. This famous book was written by Honoré d'Urfé; in spite of its absurdities it is full of talent, and succeeds, for the first time in the history of French narrative, in depicting individual character. D'Urfé was followed, with less originality, by Marin Le Roy de Gomberville (1600-74), who was the author of a Mexican romance, *Polexandre*, and by Gombauld (1570?-1666), the author of *Endymion* (1624). These were fictions of interminable adventures, broken by an infinite number of episodes; they seem tedious enough to us nowadays, but with their refinement of language, and their elevation of sentiment, they fascinated readers like Mme. de Sévigné. To Gomberville, who has been called the Alexandre Dumas of the 17th century, succeeded Mlle. de Scudéry (1607-1701), who preserved the romantic framework of the novel, but filled it up with modern and familiar figures disguised under ancient names. But in the meantime, the elephantine heroic romances were ridiculed by Charles Sorel in his *Francion* (1622) and *Le Berger extravagant* (1628). Later examples of a realistic reaction against the pompous beauty of Gomberville and Scudéry were the *Roman comique* (1651) of Scarron and *Le Roman bourgeois* (1666) of Furetière.

All these, however, were mere preparations. The earliest novelist of France is Marguerite de la Vergne, comtesse de La Fayette (1634-93), and the earliest genuine French novels were her *Princesse de Montpensier* (1662), and her far more important *Princesse de Clèves* (1678). Mme. de La Fayette was the first writer of prose narrative in Europe who portrayed, as closely to nature as she could, the actual manner and conversations of well-bred people. To show that she was capable of writing in the old style, she published, with the help of Segrais, in 1670, a *Zayde*, which is in the Spanish manner affected by Mlle. de Scudéry. It was long before the peculiar originality of the *Princesse de Clèves* was

appreciated. Meanwhile La Fontaine, in 1669, published a fine romance of *Psyché*, partly in verse, and Fénelon, in 1699, his celebrated *Télémaque*. The influence of La Bruyère on the novelists, although he wrote no novels, must not be overlooked. But the *Princesse de Clèves* remained the solitary novel of moral analysis when its author died and the 17th century closed. The successes of Lesage seemed to be wholly reactionary. His realistic novels, *Gil Blas* and *Le Diable boiteux*, depended upon their comic force, their picaresque vivacity, rather than upon the sober study of average human character. But Marivaux (1688-1763) took up the psychological novel again, and produced in *Marianne* (1731) and *Le Paysan parvenu* (1735) analytical stories of Parisian manners and character which were wholly modern in form. If *Marianne* was deliberate, the exquisite *Manon Lescaut* (1731), by the Abbé Prévost d'Exiles (1697-1763), was almost an accident; but, between them, these simultaneous works started the French novel of the analysis of emotion. The brilliant stories of Voltaire, which began with *Zadig* and included *Candide*, hardly belonged to this category; they are rather satires and diversions, in which class must also be placed the fashionable boudoir novels of Crébillon fils, La Morlière and others. But the English taste, exemplified mainly by Richardson, Sterne and Fielding, prevailed, and its effect was seen again in the imperfect novels of Diderot and Rousseau. The *Nouvelle Héloïse* and the *Émile* of the latter are not skilfully constructed as stories, but they mark the starting-point of the novel which aims at familiarizing the public mind with great ideas in an attractively romantic form. The moral purpose is equally evident in the famous *Paul et Virginie* of Bernardin de St. Pierre. It was less didactically present in Mme. de Staël's *Delphine* (1802) and *Corinne* (1807), where the misinterpreted woman of genius, so often depicted since, is first introduced to French novel-readers. It was not, however, until about 1830 that the novel began to be one of the main channels of imaginative writing in France, and the development of this kind of fiction was one of the main features of the romantic revival. Stendhal showed that, without any of the charms of style, and relying exclusively upon minute psychological observation, the record of a human life could be made enthrallingly interesting. Alexandre Dumas, under the direct influence of Sir Walter Scott, allowed his tropic imagination to revel and riot in brilliant chains of adventure. The imaginative novel was admirably conceived by George Sand. But it was Balzac who filled canvas after canvas with the astounding intensity of life itself, and who insisted with irresistible force that the function of the novel is to draw a consistent and unprejudiced picture of humanity under the strain of a succession of probable passions. This has been clearly comprehended by a host of later French novelists, whose record cannot be traced here, to be the function of the novel, as Mme. de La Fayette invented it, as Marivaux and Prévost developed it, and as George Sand and Balzac finally laid down its laws and settled its borders. Certain dates, however, must be recorded in the briefest record of the evolution of the French novel, and 1856 is one of these; in that year Gustave Flaubert published *Madame Bovary*, a work in which the rival realistic and romantic tendencies are combined with a mastery that had not been approached and has not since been equalled. Another is 1871, when Zola began to roll out the enormous canvas of *Les Rougon-Macquart*. Yet another is 1880, when *Boule de suif* first revealed in Maupassant a novelist whose creations were not merely amusing and striking, but absolutely convincing and logical.

England.—If we take no heed of translations of Latin stories, such as those from the *Gesta Romanorum*, we may say that the beginning of prose fiction in England is *Le Morte d'Arthur*, of Sir Thomas Malory, finished in or about 1470, and printed by Caxton in 1485. The great merits of this writer were that he got rid of the mediaeval burden of allegory, essayed an interpretation of the human heart, and invented a lucid and vigorous style of narrative. But his book became, as Prof. W. Raleigh has said, "the feeder of poetry rather than of prose," and it gave no inkling of the methods of the modern novel. The same may be said of such versions of the Charlemagne, Amadis and Palmeria cycles of romances as *Huon of Bordeaux*, published by Lord Berners, per-

haps in 1535, and innumerable others. It was the *novella* of Italy from which the English novel first faintly started. Between 1560 and 1580 versions of the Italian novelists became exceedingly popular in England. Paynter in introducing the tales of Bandello and Straparola struck the true novelist's note by offering them not as works of morality or edification, but "instead of a merry companion to shorten the tedious toil of weary ways." The appreciation of these Italian stories led to the composition of the *Euphues* of Lyly (1579), a book of great interest and merit, which has been called "the first original prose novel written in English." This is somewhat to exaggerate, since *Euphues* is rather a work of elegant philosophy than a narrative. Lyly had many imitators, Munday, Greene, Dickenson, Barnabe Rich, Lodge, Nash and others, who formed a school of prose fiction which was not without a certain romantic beauty, but possessed as little narrative vigour as possible. To compare a story written by Sacchetti in 1385 with one written by Greene in 1585 is to perceive that not merely had no progress been made towards the modern novel, but that a great deal of ground had been lost. The absence of the comic element in Elizabethan romances is very marked. M. Jusserand has claimed a peculiar merit in this and other respects for the *Jack Wilton* of Nash (1594), which, as he points out, is the earliest English example of picaresque literature. During the reign of the heroic romances in France, their vogue violently affected the English book-market. The huge stories of Calprenède and Gomberville were translated and imitated to the exclusion of every other species of prose fiction, between 1645 and 1670. The long-winded books of Mlle. de Scudéry, especially *Cassandra* and *The Great Cyrus*, were read so universally in England as to leave their stamp on the national manners. Of original English romances written in competition with the French masterpieces of chivalry, the *Parthenissa* of Lord Orrery (1654) is the best known. The first definite stand against these Gallicized romances was made by two dramatists, Aphra Behn and William Congreve. Congreve's *Incognita* (1692) is remarkable for its light raillery and humour, and perhaps deserves as well as any 17th century composition to be called the earliest novel in English. The stories of Mrs. Behn have the merit of a romantic simplicity in narrative, but they are dull. It was Daniel Defoe who introduced a minute and rude system of realistic observation which exactitude he combined with a survival of the old picaresque method, the result being those entertaining works *Colonel Jack* (1722) and *Roxana* (1724). He came to positive success in the immortal narrative of *Robinson Crusoe*.

The 18th Century.—Not even yet had the English novel been invented. It came into the world in 1740 from the unconscious hands of Samuel Richardson (1689–1761), who had hit upon the notion that morality might be helped and young persons of inexperience protected by the preparation of a series of letters exchanged between imaginary persons. The result was *Pamela: or Virtue Rewarded*. Henry Fielding's *Joseph Andrews* (1742), which started as a mere burlesque of *Pamela*, proceeded upon admirably original lines of its own, in a study of the humours and manners of contemporary country life. Fielding rejected the epistolary artifice of Richardson, and told his story in a straightforward narrative, broken indeed by arguments and ejaculations which bound the new novel to the old essay of the *Spectator* type. The creative force of Fielding filled the pages of this book with a crowd of vividly-presented characters, and this marked a step in advance. In 1748 appeared the *Roderick Random* of Smollett, and here we have neither the sculptural manner of Richardson nor the busy world of Fielding's realism, but a comic impression founded on an artful employment of emphasis and exaggeration. The next move was made by Fielding, who in 1749 published his *Tom Jones*. Starting with the pungent horror of hypocrisy ever before him, Fielding constructs a fragment of the world in which men and women are seen without exaggeration, plying their daily trades under the eye of an impartial observer who can penetrate to their secret motives. This was a great advance, and a still greater one was the sustained skill with which the author conducted the plot, the interwoven series of the actions of his characters. It may almost be said that until the publication of *Tom Jones* no novel with a real plot had been conceived in English.

The rivalry of the great novelists of this time was of signal help to them, and there can be no question that the astounding richness of *Tom Jones* stirred Smollett to the exercise of increased energy in *Peregrine Pickle* (1751), a coarse and savage book, illuminated by brilliant flashes of humour. A better, because a tenderer and truer study of life was *Amelia*, which Fielding published in the same year; yet most readers have found this novel a little languid after *Tom Jones*. Now Richardson, who had long been silent, reasserted his mastery of epistolary analysis in the huge *History of Sir Charles Grandison* (1753), in which, as its admirers claimed, "all the recesses of the human heart are explored and its whole texture unfolded."

New forms, and also new subjects, were to present themselves to the imagination of capable British novelists, but the starting-point of every experiment was to be discovered in the ripest work of Richardson, Fielding and Smollett. Their influence was manifest in the writings of the second school of English novelists, in whom, however, several interesting varieties of subject and treatment were discovered. The *Tristram Shandy* (1759–66) of Sterne, is the most masterly example in English of a humour which goes direct to pathos for its most "sentimental" effects, and of the kind of loosely-strung, reflective fiction which is hardly a narrative at all. Neither *Tristram Shandy* nor *A Sentimental Journey* (1768) can properly be included among novels. In *Rasselas* (1759) Dr. Johnson showed that the new kind of writing could be used to give entertainment to a sermon, and in this he was to have a multitude of followers. In *Chrysal* (1760) Charles Johnstone (d. 1800) showed that the picaresque romance could still exist, tinged by the newly-found art of the novelist. In *The Castle of Otranto* (1764) Horace Walpole adapted the methods of the novelist to a pseudo-historical theme of horror and romance, and prophesied of Walter Scott. In *The Vicar of Wakefield* (1766) Oliver Goldsmith was indebted to most of his immediate predecessors, but fused their qualities in an amalgam of gentle wit and delicate sweetness and conversational brevity which has made his one loosely-constructed novel a foremost classic of our literature. Thus, in the one quarter of a century which divides *Pamela* from *The Vicar of Wakefield*, English novel-writing was born, grew into full maturity, and adopted its adult and final forms. During the remainder of the 18th century, little or nothing was done to extend the range of prose fiction in England, but one or two of those departments of novel-writing which had already been invented were developed and adapted to changing taste. In particular, the rapid increase of reticence and refinement in conversation made such a novel in letters as Smollett's *Humphrey Clinker* (1771) repulsively coarse to women of delicacy, who were charmed on the other hand with the *Evelina* of Frances Burney (1778). These two typical books are composed on the same plan, yet essentially a whole age lies between the former and the latter. What has been called "the novel of the tea-table" now came into existence, and the 18th century was about to close in mediocrity, when its credit was partially saved by a development of Horace Walpole's romance of terror in the vigorous and sensational narratives of Anne Radcliffe (1764–1823), whose *Mysteries of Udolpho* appeared in 1794. The same year saw the publication of *Caleb Williams*, in which William Godwin (1756–1836) evolved a tragic theory of politics.

The 19th Century.—The two schools here indicated, and they may be roughly defined as the school of the Tea-Table and the school of the Skeleton-in-the-Cupboard, did not, however, betray their real significance until the second decade of the 19th century, when they developed into the novel of psychological satire and the romance of historical imagination. Two writers, the greatest who had yet attempted to address English readers through prose fiction, almost simultaneously came forward as the protagonists in these two spheres of work. Jane Austen published *Sense and Sensibility* in 1811, Walter Scott *Waverley* in 1814. These were epoch-making dates; in each case a new era opened for the countless readers of novels. The first-named writer, all exactitude, conscience and literary art, worked away at her "little bit (two inches wide) of ivory"; the other, with bold and flowing brush, covered vast spaces with his stimulating and noble compositions. It is,

however, to be noted that the isolation in which we now regard these great writers—a *solitude à deux* only broken in measure by the presence of Miss Maria Edgeworth—is an optical illusion due to the veils of distance. The bookshops from 1810 to 1820 and onwards were thronged and glutted with novels, many of them infinitely more successful, so far as sales were concerned, than the most popular of Miss Austen's works. The novels of Miss Austen were written between 1796 and 1816, although published from 1811 to 1818; those of Sir Walter Scott date from 1814 (*Waverley*) to 1829 (*Anne of Geierstein*).

The next artist in prose fiction whose force of invention was sufficient to start the novel on wholly fresh tracks was born 40 years later than Scott. This was Charles Dickens, whose *Pickwick Papers* (1836) marks another epoch in novel writing. His career of prodigal production ceased abruptly in 1870, by which time it had long been obvious that he was the pioneer of a great and diverse school of novelists, all born within the second decade of the century. Of these Thackeray was not really made obvious until *Vanity Fair* (1849), nor Charlotte Brontë till *Jane Eyre* (1847), nor Mrs. Gaskell till *Mary Barton* (1848), nor George Eliot till *Adam Bede* (1859). The most noticeable point on which the five illustrious novelists of the Early Victorian age resembled one another and differed from all their predecessors, was the sociological or even humanitarian character of their writings. All of them had projects of moral or social reform close at heart, all desired to mend the existing scheme of things. (E. G.)

AMERICA

In America during the greater part of colonial life before the Revolution there was no fiction written because there was no fiction-reading public. After the middle of the 18th century novels began to find their way into the hands of the curiosity-seekers and adventurers in literature. By 1800 a change had come. Naturally among the English colonies English models were followed in fiction quite as closely as they already had been in architecture, music, poetry and the drama. Three women wrote of a Richardsonian world as sentimentally as their master: Sarah Wentworth Morton in *The Power of Sympathy* (1789), Susanna Haswell Rowson in *Charlotte* (1794), later *Charlotte Temple* and Hannah Webster Foster in *The Coquette* (1797). Gilbert Imlay in *The Emigrants* (1793) superimposed the formula for Frances Burney's stories of the English town on a shifting American scene from the seaboard over the Alleghenies to the western valley of the Ohio river. Hugh Henry Brackenridge between 1792 and 1805 published the successive parts of *Modern Chivalry*, and wrote them avowedly after the fashions of Hume, Swift and Fielding. Royall Tyler smacked rather more of Smollett in *The Algerine Captive* (1797).

The reading of William Godwin's *Caleb Williams* (1794) led Charles Brockden Brown (1771-1810) to attempt the treatment of a social thesis in the "Gothic" manner. *Arthur Mervyn* (1799-1800), especially in the first half, pursued Godwin's theme of an innocent youth branded as an outlaw by the malignance of a guilty patron. In both *Arthur Mervyn* and *Ormond*, another English predecessor, Defoe, with his *Journal of the Plague Year* (1722) is paralleled in Brown's lurid circumstantial memories of the yellow-fever epidemics in Philadelphia, 1793, and New York city five years later. In his most completely gothicized story, and his most powerful one, *Wieland* (1798), Brown dealt with a devastating pseudo-supernatural influence rationalized away as a feat of diabolical ventriloquism. In *Edgar Huntly* (1799), he turned to frontier adventure in anticipation of Cooper.

Twenty years later James Fenimore Cooper (1789-1851) discovered in his negligible, domestic romance *Precaution* (1820) that he had a hitherto undiscovered gift. Stimulated by friendly critics to write of matters more nearly native to his experience, he followed with *The Spy* (1821), a tale of the Revolution, which was set in his own neighbourhood, with *The Pioneers* (1823), a story of the frontier on which he had grown up and with *The Pilot* (1824), a sea-story for which his years in merchant shipping and the navy had equipped him. With these three tales, American in subject matter and point of view, natural and spirited in treat-

ment and peopled with real characters acting against real backgrounds, the genuine American novel came into existence. In his nearly 30 years of authorship Cooper completed the Leatherstocking series of which *The Pioneers*, first to be written, is fourth to be read. The others in story progression are *The Deerslayer* (1841), *The Last of the Mohicans* (1826), *The Pathfinder* (1840) and *The Prairie* (1827), in which he showed how vainly he struggled to reconcile aristocratic prejudice with democratic theory.

By the time of Cooper's death in 1851 the output of novels, which largely paralleled his in their resort to the settlement, the frontier and the Revolutionary War, was considerable in size but inconsiderable in value. In New England John Neal, with *The Down-Easters* (1833), D. P. Thompson, with *The Green Mountain Boys* (1839) and Sylvester Judd, with *Margaret* (1845) took up the chronicle. J. P. Kennedy expounded Virginia in *Swallow Barn* (1832) and the Carolinas in *Horse-Shoe Robinson* (1835). And the inclination to follow the retreating frontier was marked by J. K. Paulding's *Westward Ho!* (1832), R. M. Bird's *Nick of the Woods* (1837) Mrs. C. M. S. Kirkland's *A New Home—Who'll Follow* (1839) as well as by most of the voluminous work of Wm. Gilmore Simms (1806-70). Just as Cooper was often referred to as the American Scott, Simms, with better reason, was frequently called the Southern Cooper. He complemented Cooper's success with the frontier by his own with the settlement and the Revolution. Of his seven novels of the war *The Partisan* (1835) is the sturdiest survivor, and of his many tales of the settlement, *Beauchampe* (1842) is perhaps pre-eminent.

In these years, however, Herman Melville (1819-91) began the work which culminated in the year of Cooper's death with *Moby Dick* (1851), one of the greatest novels of the century in the English language. Several years in early manhood spent in merchant shipping and whaling supplied him with his philosophic point of view and with most of his material. *Typee* (1846) and *Omoo* (1847) were the first literary fruits of his wanderings, a continuous narrative of South Sea adventure interlarded with drastic criticism of the invading whites. *Mardi* (1849), retaining all his zest for the sea, passed over to the realm of allegory from which Melville was never to return, in the tale of a world-wide quest for Unattainable Beauty, incarnate in the maiden, Yillaz. And *White Jacket* (1850), the story of his return to Western life on an American warship, is characteristic of its author in its combination of cyclopaedic fact and elaborate allegory. *Moby Dick*, Melville's masterpiece, the pursuit of a hopeless conflict with fate waged by Captain Ahab, a Promethean whaler, is a story which moves with grim relentlessness to its tragic conclusion. With *Moby Dick* Melville's major achievement was at an end, though the early successes cannot be fully understood without careful reading of *Pierre* (1852), *Israel Potter* (1855), *Piazza Tales* (1856), *The Confidence Man* (1857), his privately printed verse and the posthumous novel *Billy Budd* (1924).

America had as yet shown no bent for realism in fiction except in one or two distorted satires by Cooper. The turn to Nathaniel Hawthorne (1804-64) is a turn only to another type of romance. An unusually long period of solitary preparation, marked only by a few score short tales and sketches brought him to maturity and recognition at the age of 46 with *The Scarlet Letter* (1850). He is known as a novelist for *The Blithedale Romance* (1852), *The House of the Seven Gables* (1851) and *The Marble Faun* (1860); although in addition to the suppressed *Fanshawe* (1828), *Septimius Felton* (1872), *Dr. Grimshawe's Secret* (1882) and the uncompleted *Dolliver Romance* were all posthumously published. His romances proceed almost by formula, each dominated by a physical symbol, each told in terms of a small group of characters with a hyper-sensitive central figure, each developed mainly through analysis and interpretation of the changing moods of the markedly inactive actors, each garnished with many a meditative commentary on the text, each critical of the Puritan tradition which dominated the author's past and present and each inquisitive as to the mystery of life and the hidden sources of its visible phenomena.

The decade which was ushered in by *Moby Dick* was escorted to its end by a host of sentimental tales for girls and robust

adventure stories for boys. Only one novel was taken seriously by adults, Mrs. H. B. Stowe's (1811-96) enormously successful propagandist tale, *Uncle Tom's Cabin* (1852). Mrs. Stowe felt no pride in it as a story, but as a popular document she composed it with great skill and through it she discovered the inherent ability which she vented not only in the second anti-slavery tale *Dred* (1856), but also in a succession of discriminating pictures of New England life, of which *The Minister's Wooing* (1859) and *Oldtown Folks* (1869) are worthy of remark. Her work marks the turn to a definite current of realism.

It is not without significance that the new tendency gained momentum most rapidly in the new West. With the close of the Civil War the movement began with a fresh depiction of the American scene, and swept in a great cyclonic curve from the Pacific coast past the shores of the Gulf of Mexico, up through the South-eastern States into New England, across to the Middle West and back into the Ohio valley, until every part of the country was represented by its descriptive story-tellers. The course of this newer provincial fiction is suggested by such book titles as Mark Twain's *Jumping Frog* (California, 1867); Bret Harte's *The Luck of Roaring Camp* (California, 1871); G. W. Cable's *Old Creole Days* (Louisiana, 1879); Joel Chandler Harris's *Uncle Remus: His Songs and Sayings* (Georgia, 1880); Charles Egbert Craddock's (Mary N. Murfree) *In the Tennessee Mountains* (1884); Thomas Nelson Page's *In Ole Virginia* (1887); Mary E. Wilkins's *A New England Nun* (1891); Hamlin Garland's *Main Traveled Roads* (1891); James Lane Allen's *Flate and Violin* (1891).

Mark Twain (Samuel Langhorne Clemens, 1835-1910) was an insistent anti-sentimentalist and anti-traditionalist, and free from any dominating literary influence. His *Innocents Abroad* (1869) was an account of what he saw in Europe in contrast with what the American pseudo-aesthete was supposed to see. His *Tom Sawyer* (1876) and *Huckleberry Finn* (1884) were written in honest contempt for the prevailing goody-goody boy story. *The Gilded Age* (1873), in collaboration with Charles Dudley Warner, was a relentless satire on the time, as was *The Man that Corrupted Hadleyburg* a quarter of a century later. During the latter part of his life Mark Twain wavered between a relative faith in democracy—*The Prince and the Pauper* (1882), *The Connecticut Yankee* (1889), *Joan of Arc* (1896) and a positive despair in humankind—*What is Man?* (1906) *The Mysterious Stranger* (1916) and other posthumous works.

William Dean Howells (1837-1920) was the only American to rival Mark Twain in the long period when they were contemporaries and friends. Howells's career falls into two clearly marked periods before and after he had come under the acknowledged influence of Tolstoi. A trained observer in the school of journalism, he was content in the first period to focus his attention on the interplay of contrasting cultures, Western and Eastern, American and European, as in *A Foregone Conclusion* (1875), *The Lady of the Aroostook* (1879), *The Rise of Silas Lapham* (1884) and *Indian Summer* (1886). But when, through Tolstoi, he "began at last to discover [his] relations to the race," his novels, while retaining their earlier charm, carried on their shoulders the Pilgrim's pack of a social burden, as in *A Hazard of New Fortunes* (1889), *The Quality of Mercy* (1892), *The World of Chance* (1893), *A Traveler from Altruria* (1894) and many another. He was extremely prolific, though scrupulous in his art; and he exerted a wide influence over the oncoming generation.

Henry James (1843-1916) furnishes an inevitable parallel to Howells. Throughout his authorship he followed the path of the psychological realist from which Howells was diverted in mid-career. In this pursuit he penetrated to the inner shrines of sophisticated life: *The American* (1877) presents a robust compatriot cruelly wronged by an alien society. Later, American society had become alien to James. The writing of *Washington Square* (1881) a purely American narration, made him "feel acutely the want of the 'paraphernalia,'" of a matured society. *The Portrait of a Lady* (1881) he built "large, in fine embossed vaults and painted arches" which were for the most part located in Europe. *The Tragic Muse* (1890), one of his simplest works,

portrays the security of conservative England threatened by an invasion from the Bohemia of art. From this point on James can hardly be claimed as American. And from this point too both his thinking processes and his style became so involved as to demand the loyal and painstaking attention of a highly eclectic body of readers.

In the 1880's, the decade in which Howells learned from his Russian master to "set life forever above art" the output of American fiction had become abundant and varied. The sentimental domestic story, the romance of adventure, the historical tale, the international novel, the provincial picture and the purpose novel all flourished. From them all only a few survive in memory, and these with such religious or ethical thesis as Lew Wallace's *Ben Hur* (1880), Helen Hunt Jackson's *Ramona* (1884), Margaret Deland's *John Ward, Preacher* (1888) and Edward Bellamy's *Looking Backward* (1888). Of the novelists who emerged at this time into a popularity not without literary basis the chief was Francis R. Stockton (1834-1902), a lord of whimsical misrule in his day, and F. Marion Crawford (1854-1909), prolific author of romances located in Europe and the Near East.

The current of romance, of course, did not cease to flow, but from 1890 to 1910 the most marked tendency in American fiction was toward the ethical realism of Tolstoi or the naturalism of Zola. With the outbreak of the brief war with Spain in 1898 an awakened national self-consciousness recognized or inspired such historical novels as Weir Mitchell's *Hugh Wynne, Free Quaker* (1897), Thomas Nelson Page's *Red Rock* (1898), Mary Johnston's *To Have and to Hold* (1900), Winston Churchill's *Richard Carvel* (1899) and Paul Leicester Ford's *Janice Meredith* (1899). More important than this were the social novels reflective of Howells's later period written by Hamlin Garland, Brand Whitlock, Winston Churchill and Thomas Nelson Page, and still more important was the fresh naturalism of Stephen Crane (1871-1900) in *Maggie* (1896), *George's Mother* (1896) and the extraordinary expressionism of *The Red Badge of Courage* (1895) and *The Open Boat* (1898). With Frank Norris (1870-1902) the new century was greeted in another succession of naturalistic stories of which the two members, *The Octopus* (1901) and *The Pit* (1903), of the incomplete trilogy, *The Epic of the Wheat*, are the most important.

The present century has seen the sustained work of one distinguished successor to Howells and James, Edith Wharton. Of the novelists in mid-career the most important are James Branch Cabell, ironic romanticist, Joseph Hergesheimer, who writes a compound of romanticism and naturalism, Theodore Dreiser and Sherwood Anderson, naturalists, Sinclair Lewis, a mordant journalist with a gift for critical narrative, and Willa Cather, the most distinguished expositor of the retreating frontier which was conquered and populated in the closing years of the 19th century.

OTHER COUNTRIES

Spain.—Prose narrative in Spain practically begins in the 15th century with chronicles and romances of chivalry, tempered occasionally and faintly by some knowledge of what had been attempted in Italy by Boccaccio. The Spanish version of *Amadis de Gaula*, in which the romance of knight errantry culminated, belongs to 1508; the lost original is supposed to have been Portuguese. This was the only book of its class which is saved from the burning in *Don Quixote*; it was followed by *Palmerin of England*. These interminable books and a hundred worse than they, occupied the leisure of 16th century readers of both sexes. Without approaching the form of novels, they prepared the ground for novel-reading. The exploration of America led to the composition of monstrous tales of the New World, which generally took the form of continuations of *Amadis*. A new thing was begun in 1554, when the anonymous picaresque romance of *Lazarillo de Tormes* started the story of fantastic modern adventure; this highly entertaining book has been called the 16th century *Pickwick*, and Fitzmaurice-Kelly remarks that it "fixed for ever the type of the comic prose epic." The pastoral romance, in the hands of Jorge de Montemayor (d. 1561), who wrote an insipid *Diana* which was

popular for a while throughout Europe, took readers a step backward, away from the ultimate path of the novel. It is of interest to us, however, to note that it was in one of these "vain imaginings," in his pastoral romance of *Galatea*, that Cervantes approached the field of fiction in 1585. Few of his peculiar merits are to be found in this early work; he turned for the present to the composition of plays. It was not until 1604 that he returned to prose fiction by printing his immortal *Don Quixote*, which made an epoch in the history of the novel. This book was originally intended to ridicule the already fading passion for the romances of chivalry, but it proceeded much further than that, and there is hardly any branch of fiction which may not be traced back to the splendid initiation of some chapter of *Don Quixote*. In 1613 Cervantes published his 12 *Exemplary Novels*; these are not so well known as the great romance, and they owed not a little of their form to Italian sources, but they are very brilliant. One of the best anonymous Spanish stories of the period, *The Mock Aunt*, is a type of excellence in facetious narrative of the sarcastic class; it has been attributed to Cervantes himself. No other novelist of Spain has moulded the thought of Europe, but the heroic romance which occupied so much of the attention of France in the 17th century was invented by a little-known Spanish soldier, Pérez de Hita, who, about 1600, wrote fantastic stories about Granada and the Moors. The farcical romance of *Fray Gerundio de Campazas*, 1758, by J. F. de Isla (1703-18) competed in popularity with *Gil Blas*. Speaking broadly, however, Spain made no appreciable progress in novel-writing from the days of Cervantes to those of Walter Scott, when the *Waverley Novels* began to find such artless imitators as Martínez de la Rosa and Zorrilla. But the first original novelist of Spain was Cecilia Böhl de Faber (Fernán Caballero) (1796-1877), whose *La Gaviota* (1848), a study of life in an Andalusian village, was the earliest Spanish novel, in the modern sense. She was followed by Valera (1824-1904), by Alarcón (1833-91), by Pereda (1834-1906), by Pérez Galdós (1845-1920) and by Palacio Valdés (b. 1853), in whom the tendencies of recent European fiction have been competently illustrated without any striking contributions to originality.

Germany.—The cultivation of the novel in its proper sense began late in Germany. It is usual to consider that H. J. C. von Grimmelshausen (1625?-75) as the earliest German novelist; his very curious romance, *Abenteuerliche Simplicius Simplicissimus*, was printed at Mömpelgard in 1669. This is an account of the adventures of a simple-minded fellow during the Thirty Years' War, and is a chain of episodes, brilliantly recorded, but hardly a novel. Early in the 18th century, an extraordinary number of imitations of Defoe's great romance were published in Germany, and these are known to scholars as the *Robinsonaden*. Later on, Wieland imitated *Don Quixote*, but the earliest German novel which possesses original value is the celebrated work of Goethe, *The Sorrows of Young Werther* (1774). The still more celebrated *Wilhelm Meister* did not appear until 1796. A third novel, *Elective Affinities*, was published by Goethe in 1809. Meanwhile a very characteristic group of picturesque stories had been issued by Johann Paul Richter (Jean Paul) (1763-1825), destined to have a wide influence upon romantic literature throughout Europe. Purely romantic were the stories of Tieck, of Brentano, of Arnim, of Fouqué, of Kleist, of Immermann. The German novelists of this period wrote like poets, deprived of the discipline of verse. In later times novels of high merit have been written by Gustav Freytag, Wilibald Alexis (1798-1871), called the German Walter Scott, Laube, Fontane, Ebers, Jeremias Gotthelf, Berthold Auerbach, Spielhagen, Heyse and many others, but the 19th century produced no German novelist of commanding originality.

Russia.—In Russia alone, among the countries of central and eastern Europe, the novel has developed with a radical originality. Until the second quarter of the 19th century the prose fiction of Russia was confined to imitations of Sir Walter Scott, but about the year 1834 Gogol (1809-52) began to revolt against the historico-romantic school and to produce stories in which an almost savage realism was curiously blended with the Slavonic dreaminess and melancholy. Since then the Russian novel has consistently been the novel of resignation and pity, but wholly divorced from

sentimentality. Gogol was succeeded by Gontcharov, Tourgeniev, Dostoïevski, Pissemski (1820-81) and Tolstoi, forming the most consistent and, doubtless, the most powerful school of novelists which Europe saw in the 19th century. The influence of these writers on the rest of the world was immense, and even in England, where it was least acutely felt, it was significant.

Oriental.—In a primitive form the novel has long been cultivated in Asia. It was introduced into China, but whence is unknown, in the 13th century, and Le Kuan-chung was the first Chinese novelist. The productions of this writer and of his followers are tales of bloody warfare, or record the adventures of travellers. The novel called *The Twice-Flowering Plum-Trees*, belonging to the 16th (or 17th) century, is a typical example of the moral Chinese novel, written with a virtuous purpose. Prof. Giles holds that the novel of China reached its highest point of development in *The Dream of the Red Chamber*, an anonymous story of the end of the 17th century; this is a panorama of Chinese social life, "worked out with a completeness worthy of Fielding." Prose stories began to be met with in the literature of Japan early in the 10th century. But the inventor of the Japanese novel was a woman of genius, Murasaki no Shikibu, whose *Genji Monogatari* has been compared to the writings of Richardson; it was finished in 1004 and may, therefore, be considered the oldest novel in the world. This book, which is one of the great classics of Japan, was widely imitated. After the classic period novel-writing was long neglected in Japan, but the humours of 17th century life were successfully translated into popular fiction by Saikaku (1641-93), and later by the collaborators Jisho and Kiseki. (E. G.)

NOVEL, MODERN DEVELOPMENTS IN THE.

Towards the close of the last century, there arose as a reaction from the naturalistic novel, a school of neo-romantic psychologists, sceptically sentimental, and fond of lyrical "nuances." Types such as Oscar Wilde's *Dorian Grey* were popular, also the gentle, pallid, aristocratic, weary heroes of the Danish author, Hermann Bang. The erotic was the favourite theme, either sublimated, delicately portrayed in many beautiful shades, or else traced in glowingly pathetic frescoes. Atmosphere, tact, a great knowledge of women, good form, scepticism, and up-to-date-ness were the qualities valued in a novelist. Leading literary criticism asserted that Art has little to do with character and all that was written was appraised in accordance with a strongly underlined "Art for Art" principle.

The New Novelists.—Strange to say, only a few of the novelists who in the long run proved themselves great and lasting belonged to this tendency favoured by official literature. Independently of it, it may be mentioned, Romain Rolland wrote his vast life history of the musician Jean Christophe, and Anatole France his gentle, sceptical, wise novels. Rudyard Kipling composed his ballads and his great ballad-like Indian tales, and, following on Dostoïevski and Tolstoi, Maxim Gorki appeared, melancholy and powerful upon the European horizon. Independently also of this officially favoured tendency August Strindberg cried aloud his maniacal, embarrassing confessions; Hamsun, with biting lyrics, placed his quiet, queer characters in a grand landscape; Selma Lagerlöf wrote her wild, sweet novels; and Johannes V. Jensen transformed the doctrines of Darwin and his own views on America into literature.

Of American novelists after E. A. Poe and Mark Twain no

more were sighted in the continent of Europe. A master of story writing of the rank of Stevenson was at best only known there through little read translations of *The Master of Ballantrae* and *Treasure Island*. Strindberg's novels, hardly accepted by a wider public, aroused in the connoisseurs admiration and displeasure. Dostoevski and Tolstoi were looked upon by the Europe of their day as gifted lunatics in much the same way as was Shakespeare by the French of the 18th century. It was Paris that dominated. France—at least in fiction—played the part which Greece had played in the ancient world. French novels even of mediocre importance were everywhere translated and imitated. They ruled the entire East, Russia, the Balkans. Practically the whole of European society modelled itself, in all aesthetic questions, on the pattern portrayed in this novel. Only that which had withstood the criticisms of the Paris salons was considered as of real artistic merit. Each country sought to adapt the French mode to its own atmosphere. In Italy, D'Annunzio exaggerated the main feature of the French style, pathetically overcolouring it. In Hungary, the French style was highly seasoned, banalized and provincialized. Among German-speaking authors the Viennese especially showed great zeal in emulating the French example. They decreed, nearly without any contradiction, that love, comedy and death should be the themes of literature.

Novels After the World War.—With the war the position of the novel changed swiftly and fundamentally. At the front the boredom of the trenches, at home the want of other distractions, won for the novel new readers, who, accustomed to a hard existence, compelled to struggle with stark reality, found that literature was dealing with affairs of secondary importance and did not touch the real centre of life, at any rate, not of their lives. They had no use for the erotic futilities, for the artistic "drawing room" philosophy of life, for the psychology—subtle as it was superficial—so popular in literature. They demanded reality. If, up till now, the reader had been drawn to the novel by a longing for entertainment and suspense, now it was the films which responded to this longing in a more agreeable and intensive way.

All around were to be seen vast changes, social and political; in the common life of every day, almost every function had been enormously changed through technical progress; Russia and America now appeared as decisive factors on the horizon of the rest of the world. The reader now demanded of the novelist that he should weigh the merits of these problems; at any rate, that he should expose them and catalogue them clearly. The author now suddenly found himself confronted with a much more alert, more distrustful, and more illuminated public.

Changing Subject-Matter.—The erotic, with its innumerable species, now moves away from the centre. No longer are the members of the ruling classes the only popular heroes of novels. Substance to the front; the artistic into the background! Even the old subject-matter is looked upon in a new light. Instead of portraying the setting of a period, the novel now sheds light on its social and economic structure, on the sociological aspect instead of on the erotic. It gives a representation and analysis of facts instead of coloured, lyrical, sentimental impressions.

This revolution did not accomplish itself without an aesthetic struggle. The antithesis, ever popular—especially in Germany—between the descriptive writer ("Schriftsteller") and the creative poet ("Dichter") was emphasized afresh, defended and attacked with animosity. The question was discussed as to whether the novel was in principle a form of poetry or not. The decay of the epic in every form was proclaimed. Distinction was drawn between creations (of poetical fancy) and (mere) description. A German historian of literature proclaimed that the mission of German literature was the romantic, and that this rationalistic period was an empty hour for German poetry.

Intermediate tendencies are perceptible. Towards the end of the war and immediately after it there broke out all over Europe a tendency to make the novel pathetic and prophetic. Even in fiction, writers like to fling open their inmost hearts and to cry aloud with wild bluff gestures that society was badly organized but that Man was good. This tendency only lasted a short time. Shorter still lasted the symbolical tendency which flared up afresh

in various literatures. In contrast to these passingly fashionable vacillations the main rationalistic tendency, which since the war has gained the upper hand in every literature, is all the more clearly distinguishable.

The Poetical Novel.—The purely poetical novel proceeding from the individual poetic vision which follows exclusively the author's need of self-expression, not aiming at the exposition of a great continuity of ideas, nor at a fixed sociological goal, has, in this quarter of a century, found great representatives. But their influence rarely extends beyond readers of their own mentality, or beyond the poetic perceptions of their own intellectual atmosphere. Germany counts a whole series of such novelists, of doubtless great talents, whose native limitations and restrictions, however, bar their way to international importance: Hermann Hesse, Jakob Schaffner, Emil Strauss, W. von Scholz, H. Stehr and Arnold Ulitz.

Scandinavians, Swiss and Dutch have also produced the same kind of remarkable but limited novels. (Two noteworthy examples offer themselves by way of contrast, the English-writing Pole, J. Conrad, and the English-writing Swiss, John Knittel.) The great poet Knut Hamsun has unquestionably world-wide literary fame; but while, before the war, he found many imitators, to-day his reputation is greater than his influence. Among the Anglo-Saxons of this class, Rudyard Kipling rose to international importance, while the great Thomas Hardy has not to this day penetrated beyond the Anglo-Saxon world.

Romance and Colour.—The romantically artistic novel had, at the beginning of the century, to a great extent, replaced the naturalistic novel. Great was the delight in colour, in play of phantasy, in the sparkling, polished word. From Italy, D'Annunzio launched a pathetically high flown style. In Germany, Heinrich Mann triumphed with the strong colours and gestures of his fiction, finding numerous minor imitators; Eduard Stucken extended the wide, brilliant horizon of his books; and Alfred Döblin exaggerated this style, overcolouring it, turning it into a grotesque turmoil of gestures and actions. In Spain, Miguel De Unamuno; in France, André Gide; in England, Chesterton, clothed what they had to say in fantastically glittering forms. Nor did the delight in colour lose itself later on. For example, in America to-day, Joseph Hergesheimer artistically and playfully blends his ice-cold, glowing psychology with a hitherto unheard of variety of colour. Nevertheless, this delight in colour is being pushed into the background by the demand for substance, for a clear outline, for stronger, more controllable construction.

The purely fantastical, purely Utopian novel provides documentary evidence of the rationalizing tendency of the times. At the beginning of the century Hanns Heinz Ewers strives after effect in his ghastly stories; Gustav Meyrink writes his mystically magical novels. In France, Renard applies his extraordinary art of story telling to fantastic themes. But since the World War the lawless roaming of imagination has been rendered more and more difficult; its direction is more and more decided by a biological and sociological point of view. The dream landscapes of the great vision of the Bohemian poet, Franz Kafka, are psycho-analytically traced out, and the Utopian novels of H. G. Wells are carefully founded upon the results of modern research.

Films and Fiction.—The films, with their manifold opportunities for creating suspense, with their immediate appeal to the senses, are becoming a dangerous competitor to the purely fictional novel, written merely for the sake of telling a story. Some authors of the anecdotal novel take refuge in an artistically refined, at times pseudo-classical technique, as for instance Paul Ernst, or Bruno Frank, also Thomas Mann (in *Death in Venice*, in his short stories), and in England such writers as D. H. Lawrence. As this epoch has a whole series of authors of vigorous imagination and original delight in story telling an astonishingly high level is reached in this field. Writers such as M. Renard, Blasco Ibañez, Margaret Kennedy, Leo Perutz and Wilhelm Speyer and Franz Molnar write entertaining novels of a considerably higher quality than is to be found in the entertaining novels of a former period. Some of these stories are very pointed and not without ingenious jests; most of them penetrate into

other fields, attaching themselves carefully to the historical or to the sociological. Or with worldly wise, cleverly interpreted imagination they paraphrase on actual life (Maurois, the life of Shelley in *Ariel*, and Maugham, the life of Gauguin in *The Moon and Sixpence*). A very fortunate combination of circumstances has made *The Adventures of the Brave Soldier, Schwejk*, by Jaroslav Heseck, a sort of national epic of international reputation.

At the beginning of the century the society novel possessed important exponents, who found numerous imitators. Fritz Mauthner, Guy de Maupassant and young Bernard Shaw wrote their criticisms of society. These were justified at the time, as the conventions of society were still a problem. To-day, when they are so no longer, criticism of society is at most a pretext for authors who wish to preserve the society novel as a portrait of the fashionable world—Arlen, Dekobra, Morand, Colette and Pitigrilli. Even in Germany, where society in this special sense of the word has never existed, the society novel is now being attempted; Edschmidt and Speyer.

Psychology and the Novelist.—At the close of the last century the psychological novel was at its height. Taught by Dostoevski, leading authors in every literature sought more and more to shade the characters of their novels, to differentiate them more and more finely (Meredith, Wassermann, Henrik Pontoppidan, and Theodore Dreiser). But whilst at the beginning of this century it was the individual case, the glaring, sensational case that was the chief interest, the novelist now lays the chief stress on portraying the individual going to mingle with the masses. The Russians of the school of Dostoevski; the followers of Chekhov, writers such as T. Shmeliov and their fellow-aspirants, are overshadowed by the sociologically inclined pupils of Tolstoi and Gorki. The books of the Viennese authors, such as Schnitzler and Stefan Zweig, and their languid knowledge of the human heart, with their esprit and their idle cautious psychology, are being dislodged by the books of the Anglo-Saxons, Galsworthy, Bennett and Sinclair Lewis, in which the hero interests, not as an individual, but as a type. If psychology be admitted at all, then much colder and more unsentimental artistic shading is demanded by the younger school (somewhat after the style of Joseph Hergesheimer), or scientifically founded psycho-analysis, as, for instance, is attempted by James Joyce.

Novels with a Purpose.—The novel with a purpose, the novel with a thesis, triumphs. Already, their titles openly proclaim such themes as: "Not the Murderer, but the Murdered is Guilty," "All Roads Lead to Golgotha," "Thou Mayest Commit Adultery," "Man is Good." In Germany, Heinrich Mann emphasizes with force the democratic, humanistic tendency in his great biting novels dealing with the Kaiser's period. (The development of the times shows itself typically in this author. He begins with criticisms of society, then writes highly-coloured, romantically artistic books with a psychological strain, whose subject-matter consists of tempestuous emotions, fierce landscapes, and an intensely demoniacal heroine. To-day, he is writing great sociological novels with a purpose.) Everywhere there appear violent anti-war novels. Already, long before the war, Bertha von Suttner had the greatest success with her weak, well-meant, pacifist novel, *Down with Arms*. Some of the anti-war novels, *Fire*, by Barbusse; *Three Soldiers*, by Dos Passos; *Sergeant Grischka*, by Arnold Zweig, although undisguised polemics, created a directly artistic effect. The didactic political tendency becomes strongly accentuated. Originating in Russia, there arises a mixture of fiction-writing and a reporting of facts. Moreover, the moment favours bellicose emotions, and clear, undisguised attitudes. The gentle scepticism of Anatole France is too quietistic for these times. Strongly polemic themes predominate throughout the Utopian, society-criticizing novels of Wells. Broadly didactic passages may already be found in Tolstoi's *War and Peace*. Upton Sinclair's novels, however, are solely and purely propaganda fiction, in which the rhetoric greatly outweighs the creative tendency. The novels of the Soviet writers (Gladkov's *Cement* and Kollontai's *Ways of Love*) are also unscrupulous propaganda. On the other hand, in the novels of the Americans, Jack London, Sinclair Lewis, Dos Passos, and

Theodore Dreiser, propaganda is subordinate to creative desire.

The Historical Novel.—The historical novel, as it was presented at the close of the last century, springs from a delight in gaily-coloured story telling and in the decorative. *Ben Hur*, by Wallace, and *Quo Vadis*, by Sinkiewicz, creates enthusiasm in millions of readers. In Germany, Alfred Doebelin, in his books *The Three Leaps of Wan Lung* and *Wallenstein*, brings to perfection the artistically-coloured novel as based upon the works of Flaubert and of the Swiss author, C. F. Meyer. But it is just in the historical novel and its metamorphoses that the tendency of the times is most clearly to be traced. Whilst, before the World War, the historical novel was popular due to its colour and its background, after the war it was the pragmatism that was sought for in it. It was popular because it strengthened in the reader the illusion of reality and imparted to him a conviction of documentary evidence and reliability. The Russian novels of D. Merejkovski form a connecting link between the earlier kind of historical novel and the modern one.

Two styles seem to be the peculiarity of the historical novel of to-day; the biographical, with a psychological strain (Maurois, Emil Ludwig, and Werfel in his *Verdi*), and especially the new historical novel which does not restrict itself to portraying, in the form of a sensational anecdote, an individual drawn more or less graphically after the person of the author, but in which the characters are embedded in the environment of their period, in which is traced an outline of the structure of the times. The author of this new historical novel does not lay stress on the colour of a period, but on its substance. He does not care for what is curious and strange, does not seek to emphasize the romantic. He does not underline those qualities which mark the distance between those times and our own, but preserving historical reality, he underlines the very qualities which are common to our own time (Feuchtwanger's *Jew Süss* and *The Ugly Duchess*). In this way does he trace unchanging man through the everchanging periods of history and endeavours to transform history into politics.

Sociological Fiction.—Here he touches the field in which the modern novel flourishes best, the sociological. Since to-day the individual is linked more than ever before with the whole world through newspapers, better communications, brisker exchange of merchandise, films and wireless; the sociological interests of the reader have become broader, deeper and more varied.

This sociological novel develops the novel of environment of the 19th century, as it culminated in Zola, and changes it from within. For while that naturalistic novel constructed its setting from single events carefully put together so as to cause suspense, the modern post-war sociological novel endeavours to comprehend in one glance the whole class which it portrays. It has learnt much from the films, in particular the technique of building up a comprehensive picture from many small individual pictures. (Thus, for instance, Dos Passos, in his *Manhattan Transfer*, intentionally—after the manner of the films—rings the changes between a "close-up" of the individual and a general view of the crowd, showing the simultaneousness of many events in order to give a better view of the events as a whole.) In logical transition between the Zolaesque novel and the sociological novel of to-day stand novels such as Zangwill's *Children of the Ghetto*, *The Buddenbrooks*, by Thomas Mann, and Galsworthy's *Forsyte Saga*. The sociological novels of the times, the works of Jack London, Sinclair Lewis, Upton Sinclair, Dos Passos, the books of Gladkov and Kollontai, the prose epics of Bennett, Galsworthy and Wells, take for their subject-matter not one arbitrary individual, but the whole society of to-day. It is for that reason that, notwithstanding the attractions of sport and wireless, they have won the entire world of to-day as their ardent readers, a somewhat superficial world, perhaps, but certainly a very enlightened one. Their works teach their readers to understand and to sympathize with the life of the citizen, and disclose the outlook of the proletariat. They impart a knowledge of those two opposite poles, Russia and America. And Russians and Anglo-Saxons have proved themselves masters of this form of novel, dislodging the French novel without a struggle. This new sociological fiction

has converted the novel from a luxury for the idle rich into a necessity for busy workers. For it originates, not from the need for self-expression of a single arbitrary author, but from a universal need for self-expression. (L. F.)

NOVELDA, a town of east Spain, in the province of Alicante, on the right bank of the river Vinalopó, and on the railway from Madrid to Alicante. Pop. (1920) 11,994. The country around is flat and fertile, producing much wine, dates, oranges, oil, saffron and aniseed. In the town there are tanneries, and manufactures of alcohol, chocolate and soap. The women make fine lace. At Salinetas de Elda nearby, there are warm sulphur and saline baths.

NOVELLO, CLARA ANASTASIA, COUNTESS GIGLIUCCI (1818–1908), English operatic singer, was born in London on June 10, 1818, and was trained under Miss Hill and John Robinson, at York and at Choron's academy in Paris. She returned to England after the revolution of 1830 and made her first public appearance at Windsor on Oct. 22, 1832. At the age of 14 she took the soprano part in Beethoven's "Missa Solemnis." By 1835 she was the leading soprano in England, and in 1837 appeared, by Mendelssohn's invitation, at the Gewandhaus concerts, visiting Berlin, Dresden, Prague, Vienna, etc., after which she studied opera for a year at Milan, appearing at Padua (July 6, 1841) in Rossini's "Semiramide," and later in other Italian cities. In 1843, owing to mismanagement, her engagements at Rome and Genoa clashed. She was arrested in Rome and detained at Fermo, where the governor, Count Gigliucci, fell in love with her. She returned to England, appeared at Drury Lane, and married Count Gigliucci in Nov. 1843.

After some years in retirement in Italy she was obliged by financial losses in the revolution of 1848 to take up her profession again. She appeared in opera in Rome and Lisbon in 1850, and in London (1851) in Handel's "Messiah." She sang in opera at Milan in the carnivals of 1854–56, but in England became the leading concert soprano. She retired finally in 1860, living with her husband at Rome and Fermo. She died on March 12, 1908.

NOVELLO, VINCENT (1781–1861), English musician, son of an Italian who married an English wife, was born in London on Sept. 6, 1781. He was a chorister at the Sardinian chapel in Duke Street, Lincoln's Inn Fields, where he learnt the organ; and from 1796 to 1822 he was successively organist of the Sardinian, Spanish (in Manchester Square) and Portuguese (in South Street, Grosvenor Square) chapels, and from 1840 to 1843 of St. Mary's chapel, Moorfields. He was an original member of the Philharmonic Society, of the Classical Harmonists and of the Choral Harmonists, officiating frequently as conductor. In 1849 he went to live at Nice, where he died on Aug. 9, 1861. He composed an immense quantity of sacred music, much of which is still deservedly popular; but his great work lay in the introduction to England of unknown compositions by the great masters. The Masses of Haydn and Mozart were absolutely unknown in England until he edited them, as were also the works of Palestrina, the treasures of the Fitzwilliam Museum, and innumerable great compositions now well known to everyone. His first work, a collection of *Sacred Music, as performed at the Royal Portuguese Chapel*, which appeared in 1811, marks the founding of the publishing house of Novello.

His son, **JOSEPH ALFRED NOVELLO** (1810–1896), who had started as a bass singer, became a regular music publisher in 1829. He really created the business, and has the credit of introducing cheap music, and departing from the method of publishing by subscription. From 1841 Henry Littleton assisted him, becoming a partner in 1861, when the firm became Novello & Co., and, on J. A. Novello's retirement in 1866, sole proprietor. Having incorporated the firm of Ewer & Co. in 1867, the title was changed to Novello, Ewer & Co., and still later back to Novello & Co., and on Henry Littleton's death in 1888, his two sons carried on the business.

NOVEMBER, the ninth month of the old Roman year [Lat. *novem*, nine], which began with March. By the Julian arrangement, according to which the year began with Jan. 1, November became the eleventh month and had 30 days assigned to it. Nov. 11 was held to mark the beginning of winter; it is now the day

of solemn commemoration of the end of the World War. The Senate desired to rename the month in honour of Tiberius—his birthday occurring on the 16th, but the emperor declined, saying, "What will you do, Conscript Fathers, if you have *thirteen* Caesars?" The Anglo-Saxon names for November were *Wind-monath*, "wind month" and *Blodmonath* "bloodmonth."

NOVERRE, JEAN GEORGES (1727–1810), French dancer and ballet master, was born in Paris on March 29, 1727. He composed his first ballet in 1747 for the Opéra Comique. After a year spent in Berlin, he mounted the ballets of Gluck and Piccini in Paris in 1749. He was in London (1755–57) and in Lyons (1758–60). From the publication of *Lettres sur la danse et les ballets* may be dated the revolution in the art of the ballet for which Noverre was responsible. (See **BALLET**.) He was next engaged by the duke of Württemberg, and afterwards by the empress Maria Theresa, until, in 1775, he was appointed, at the request of Queen Marie Antoinette, *maitre des ballets* of the Paris Opera. This post he retained until the Revolution reduced him to poverty. He died at St. Germain on Nov. 19, 1810.

Noverre's friends included Voltaire, Frederick the Great and David Garrick (who called him "the Shakespeare of the dance"). The ballets of which he was most proud were his *La Toilette de Vénus*, *Les Jalousies du sérail*, *L'Amour corsaire* and *Le Jaloux sans rival*. Besides the letters, Noverre wrote *Observations sur la construction d'une nouvelle salle de l'Opéra* (1781); *Lettres sur Garrick écrites à Voltaire* (1801); and *Lettre d'un artiste sur les fêtes publiques* (1801).

NOVGOROD (formerly known as *Velikiy-Novgorod*, Great Novgorod), a town of Russia, in the Leningrad area, in 58° 33' N., 31° 20' E., on the navigable Volkhov, 2 m. below the point where it issues from Lake Ilmen. Pop. (1926) 31,120. The town has saw-mills and manufactures boots and shoes, candles, bricks and tiles and has a brewery and a distillery.

The date at which the Slavs first erected forts in the marshy region of the Volkhov near Lake Ilmen is unknown. That situated on a low terrace close by Lake Ilmen was soon abandoned, and Novgorod or "New-town" (in contradistinction to the Scandinavian Aldegjeborg or Ladoga) was founded by Scandinavian searovers as Holmgård on another terrace which extended a mile lower on both banks of the river. The older fort (Gorodishche) existed in the 13th century. Even in the 9th century the new city on the Volkhov exercised a kind of supremacy over the other towns of the lake region, when its inhabitants in 862 invited the Varangians, under the leadership of Rurik, to the defence of the Russian towns of the north. Down to the end of the 10th century Novgorod to a certain extent depended on Kiev; yet in 997 its inhabitants obtained from their prince Yaroslav a charter which granted them self-government. For five centuries this charter was the bulwark of the independence of Novgorod. From the end of the 10th century the princes of Novgorod, chosen either from the sons of the great princes of Kiev (until 1136) or from some other branch of the family of Rurik, were always elected by the *vyeche*; but they were only its military defenders, and their delegates were merely assessors in the courts which levied taxes for the military force raised by the prince. The *vyeche* invariably expelled the princes as soon as they provoked discontent. Their election was often a subject of dispute between the wealthy and the poorer classes; and Novgorod, which was dependent for its corn supply upon the land of Suzdal, was sometimes compelled to accept a prince from the Suzdal branch instead of from that of Kiev. After 1270 the city often refused to have princes at all, and the elected mayor was the representative of the executive. Novgorod in its transactions with other cities took the name of "Sovereign Great Novgorod" (*Gospodin Velikiy Novgorod*). The supreme power was vested in the *vyeche*. The city, with a population of over 80,000, was divided into wards, each ward constituting a distinct commune. The wards were subdivided into streets, which corresponded to the occupations of their inhabitants, each being quite independent with regard to its own affairs.

Trade was carried on by corporations. By the Volkhov and the Neva, Novgorod—then known also as Naugart and Novwerden—had direct communication with the Hanseatic and Scandinavian cities, especially with Visby or Wisby on the island of Gotland. The Dnieper brought it into connection with the Bosphorus, and

it was an intermediary in the trade of Constantinople with northern Europe. The Novgorod traders penetrated to the White Sea shores, hunted on Novaya Zemlya in the 11th century, colonized the basins of the northern Dvina, descended the Volga, and as early as the 14th century extended their trading expeditions beyond the Urals into Siberia. Two great colonies, Vyatka and Vologda, organized on the same republican principles as the metropolis, favoured the further colonization of north-east Russia.

It is said that the population of Novgorod in the 14th century reached 400,000, but the pestilences of 1467, 1508 and 1533 carried off no fewer than 134,000 persons. These figures seem to relate rather to the whole Ilmen region.

Invasions of Novgorod.—Novgorod's struggle against the Suzdal region (now the government of Vladimir) began in the 12th century. In the following century it had to contend with the Swedes and the Germans, who were animated not only by the desire of territorial acquisition, but also by the spirit of religious proselytism. Their advances were checked by battles at Ladoga and Pskov in 1240 and 1242 respectively. Protected by its marshes, Novgorod escaped the Mongol invasion of 1240-2, and repelled the attacks of the princes of Moscow by whom the Mongols were supported. It also resisted the attacks of Tver.

The first serious invasion, in 1332, was rolled back with the aid of the Lithuanians. But in 1456 the great prince of Moscow imposed a heavy tribute. Ivan III. of Moscow took possession of the colonies in the northern Dvina and the Perm regions, and began two bloody wars, during which Novgorod fought for its liberty under the leadership of Marthia Boretskaya, the mayor. In 1475-1478 Ivan III. entered Novgorod, abolished its charters, and carried away 1,000 of the wealthier families, substituting for them families from Moscow; the old free city then recognized his sovereignty. A century later Ivan IV. (the Terrible) abolished the last vestiges of the independence of the city. Having learned that a party favourable to Lithuania had been organized in Novgorod, he took the field in 1570, and entered the city (much weakened by the recent pestilences) without opposition. His followers killed the heads of the monasteries, the wealthier of the merchants and clergy, and burned and pillaged the city and villages. No fewer than 15,000 were massacred at Novgorod alone (60,000 according to some authorities). A famine ensued, and the district of Novgorod fell into utter desolation. Thousands of families were transported to Moscow, Nijni-Novgorod, and other towns of the principality of Moscow.

In the beginning of the 17th century Novgorod was taken and held for seven years by the Swedes; and in the 18th century the founding of St. Petersburg (now Leningrad) finally destroyed its trade. Its position on the water highway from the Volga to St. Petersburg and on the trunk road from Moscow to the capital, still gave it some commercial importance; but even this was destroyed by the opening of the Vishera canal, connecting the Msta with the Volkhov below the city, and by the construction of the railway from St. Petersburg to Moscow, which did not reach Novgorod. Later a branch loop linked the town with the main line and its position improved.

Antiquities.—The town consists of a Kremlin (old fortress), and of the city, which stands on both banks of the river, connected by a handsome stone bridge. The Kremlin was much enlarged in 1044, and again in 1116. Its stone walls, originally palisades, were begun in 1302, and much extended in 1490. Its historical monuments include the cathedral of St. Sophia, built in 1045-1052 by architects from Constantinople to take the place of the original wooden structure (989), destroyed by fire in that year. Apart from minor changes the building remained unaltered until its restoration in 1893-1900. It contains highly-prized relics, including 12th century bronze doors, one brought reputedly from Sigtuna, the ancient capital of Sweden. Another ancient building in the Kremlin is the Yaroslav tower. Other remarkable monuments are the church of St. Nicholas (1135), the Snamenski cathedral (14th century), and churches of the 14th and 15th centuries. Within the town itself there are four monasteries and convents, two of them dating from the 11th century and two from the 12th century; and the large number in the immediate

neighbourhood shows the great extent which the city formerly had. A monument to commemorate the 1,000th anniversary of the foundation of Russia (the calling in of the Varangians by Novgorod in 862) was erected in 1862. Another monument commemorates the repulse of the Napoleonic invasion of 1812.

NOVI PAZAR (ancient *Rashka*), the capital of the department of Novi Pazar, South Serbia, Yugoslavia, lies at the head of the fertile valley of the Upper Rashka, on the site of the ancient Serbian city of Rashka. Pop. (1921) 11,207, comprising Serbs, Albanians and some Greeks. Agriculture is the only industry. There are Roman baths in the vicinity, and in the old church of St. Peter and St. Paul, the metropolitan church of the bishopric of Rashka, Stephen Nemanya, founder of the Serbian empire, passed from the Roman to the Greek church in 1143. The town was taken by the Serbs and Montenegrins in the Balkan Wars (1912-13), and assigned to Serbia by the Treaty of Bucharest (1913).

NOVI SAD (German *Neusatz*), a town of the Voivodina, Yugoslavia. Pop. (1921) 39,147. It is the seat of a Greek Orthodox bishop, and is a prosperous town with wide, well-paved streets, public gardens, a cathedral, a hospital, schools, theatres and barracks. Novi Sad is the headquarters of one of the five Army provinces, and outside the town is a large aerodrome. There is a daily market for household commodities, and for the artistic pottery and cotton goods manufactured in the town. Before the union of the province with Yugoslavia at the close of the World War (1914-18) Novi Sad was the literary and religious centre of the Serbians in Hungary, especially since the foundation in 1864 of the *Matica Srbska*, or Serbian Literary Society. The town was founded in the middle of the 18th century, and was almost totally destroyed during the revolution of 1848-9.

NOVOCAINE, an artificial alkaloid, and the most satisfactory of the local anaesthetics introduced in recent years. The hydrochloride is employed in medicine ($C_{15}H_{21}O_2N_2Cl$) and it is a substitute for cocaine. It is very soluble in water and for subcutaneous injections is far superior to cocaine for several reasons: its solutions can be sterilized by boiling whereas cocaine would decompose; it has no irritant action and is of very low toxicity, whereas cocaine is both irritant and toxic. (See *DRUG ADDICTION AND COCAINE*.)

NOVOCHERKASSK, a town of Russia in the North Caucasian area, at the confluence of the Don and Aksai rivers, in 47° 28' N., 40° 5' E. Pop. (1926) 55,448. It manufactures cloth and machinery and is a collecting centre for corn, wine and timber exports. It was founded in 1805, when the inhabitants of Old Cherkassk were compelled to leave the site because of the frequent inundations of the Don.

NOVO-GEORGIEVSK, now *Plotskoi (q.v.)*.

NOVOMOSKOVSK, a town of the Ukrainian S.S.R., 16 m. N.E. of Dnepropetrovsk (Ekaterinoslav), in 48° 38' N., 35° 16' E. Pop. (1926) 10,564. It extends some distance along the right bank of the Samara river, a tributary of the Dnieper; its main industry is brick-making. The Zaporogian Cossacks occupied the site in the 17th century, when it was known as Samarchik. In 1687 Prince Golitsuin founded the Ust-Samara fort here, destroyed after the Treaty of Pruth (1711), but rebuilt in 1736. Near it is the Samarsko-Nikolayevskiy monastery.

NOVOROSIYSK (nóv-ò-róss'í'sk), Russian port on N.E. coast of the Black Sea in 44° 42' N., 37° 45' E., in the North Caucasian area. Pop. (1926) 65,887. It has connections with the net of Russian railways, with Baku, and with Rostov-on-Don. It has large cement works, and its exports are mainly cement, naphtha, potash, leaf tobacco and champagne, its imports being machinery, coke and coal. Its grain export-trade, formerly about 70%, is insignificant at present (1928), naphtha and cement having largely replaced it. The bay, nearly 3 m. wide at its entrance and 5 m. deep from east to west, is exposed to the violent north-east wind (bora), sweeping down from the Caucasus. There is accommodation for 36 steamers. The town became Russian in 1829.

NOVO-SIBIRSK (formerly Novo-Nikolayevsk), the chief town in the Siberian Area of the Russian S.F.S.R., in lat. 55° 6' N., long. 83° 6' E., situated on the navigable Ob river, where the

trans-Siberian railway crosses it on a 9 span bridge 30 ft. above high water level. The town was founded in 1896, but had in 1926 a population of 120,771. In 1915 a branch line was opened from Novo-Sibirsk going through Barnaul, with a branch to Biisk, and on to Semipalatinsk, and a link with the railways of the Central Asiatic Russian republics is being pushed forward rapidly (1928). There is telegraphic communication with Mongolia. The town is a centre for distributing agricultural machinery. There are also grain elevators, one with a capacity of 16,070 tons, and several well set up flour mills. Butter trains, with ice trucks, start daily for the west, and frozen meat is also exported to Leningrad and Moscow. There are three electric sawmills in Novo-Sibirsk dealing with the timber from this region. The town also exports the woodcock, hazelhen and quails. Other industries are brickmaking, iron-smelting, oil pressing, distilling, brewing, and leather preparation.

NOWATA, a city of north-eastern Oklahoma, U.S.A., in the valley of the Verdigris river; the county seat of Nowata county. It is served by the Missouri Pacific and electric railways. Pop. (1920) 4,435 (83% native white). It is the trade centre of a farming, stock-raising, and oil-producing region. The city was founded in 1889, when the Missouri Pacific came through, and was incorporated in 1892. Since 1913 it has had a commission-manager form of government.

NOWAWES, a town of Germany, in the province of Brandenburg, 2 m. E. from Potsdam, on the Berlin-Potsdam railway. Pop. (1925), 26,957. The town was founded by Frederick the Great in 1754 and in 1907 the village of Neuendorf was incorporated with it. Its industries include the spinning and weaving of jute and silk and the manufacture of cloth, electrical apparatus, boots and locomotives.

NOWELL, ALEXANDER (1507?-1602), dean of St. Paul's, London, son of John Nowell of Read Hall, Whalley, Lancashire, was educated at Brasenose College, Oxford, where he is said to have shared rooms with John Foxe. He was elected fellow of Brasenose in 1526. He became master of Westminster school (1543), and prebendary of Westminster (1551). In Mary's reign he was deprived of his prebend, probably as being a married man, before May 1554, and sought refuge at Strasbourg and Frankfurt, where he developed puritan and almost presbyterian views. He submitted, however, to the Elizabethan settlement of religion, and was rewarded with the archdeaconry of Middlesex, a canonry at Canterbury and in 1560 with the deanery of St. Paul's. His sermons occasionally created some stir, and on one occasion Elizabeth interrupted his sermon, telling him to stick to his text and cease slighting the crucifix. He held the deanery of St. Paul's for forty-two years, surviving until Feb. 13, 1602. Nowell is believed to have composed the Catechism inserted before the Order of Confirmation in the Prayer Book of 1549, which was supplemented in 1604 and is still in use. Early in Elizabeth's reign he wrote a larger catechism, to serve as a statement of Protestant principles; it was printed in 1570, and in the same year appeared his "middle" catechism, designed for the instruction of "simple curates."

NOWGONG, a town and district of British India, in the Brahmaputra valley division of Assam. The town is situated on the Kalang river. The district of Nowgong has an area of 3,699 sq.m. and a population (1921) of 397,921. It consists of a wide plain overgrown with jungle and canebrakes, intersected by numerous tributaries of the Brahmaputra, and dotted with shallow marshes. The Mikir hills cover an area of about 65 m. by 35 in the south of the district; the highest peak is about 3,500 ft. The slopes are very steep, and are covered with dense forest; reserved forests cover 500 square miles. The Kamakhya hills near the bank of the Brahmaputra are about 1,500 ft. high. On the summit of the highest peak is a celebrated temple of Kamakhya, the local goddess of love, where three annual festivals are held. The staple crop is rice. Tea cultivation and manufacture are carried on but the soil and climate are not so favourable as in Upper Assam. The section of the Assam-Bengal railway from Gauhati to the hills

passes through part of the district, and a branch runs through it from Chaparmukh to Silghat steamer station. Lumding is a railway centre of some importance.

NOWGONG, a town of India, headquarters of the Bundelkhand agency and a military cantonment, in the state of Chhatarpur, on the border of the British district of Jhansi. Pop. (1921) 7,141. It has accommodation for a force of all arms. The college for the education of the sons of chiefs in Central India, opened here in 1872, was abolished in 1898, owing to the small attendance.

NOWY SANCZ, town, Poland, in the province of Cracow. Pop. (1921), 26,300. It grew to importance along with the capital through the oriental trade in the 14th century and owed much to the patronage of Casimir the Great. It is situated near the Carpathians, in the beautiful valley of the Dunajec, in the country of the Gorale or Polish Highlanders. It has a church originally founded by the Franciscans in the 14th century.

NOYES, ALFRED (1880-), English poet, was born in Staffordshire on Sept. 16, 1880, and educated at Exeter college, Oxford. *The Loom of Years*, his first volume of poems, appeared in 1902, and his *Collected Poems* in 1910, 1920, and 1927. His *Forty Singing Seamen* (1907) and *Drake* (1908) struck the patriotic note of a poet of the sea. A volume of lectures given in America, *The Sea in English Poetry*, was published in 1913, and in 1914 he was elected to a professorship of modern English literature at Princeton university, which he resigned in 1923. He was a frequent contributor to *Blackwood's Magazine*, the *Cornhill*, etc. His other publications include: *The Wine Press* (1914); *A Salute from the Fleet* (1915); *Rada* (a play, 1915); *Walking Shadows* (short stories, 1917); *The Elfyn Artist* (new poems, 1920); *The Watchers of the Sky* (1912); *The Hidden Player* (a novel, 1912); *Aspects of Modern Poetry* (essays, 1924); *The Book of Earth* (1925) and a poetic drama, *Robin Hood*, produced in 1927.

NOYON, a city of N. France, in the department of Oise, 67 m. N.N.E. of Paris by the railway to Brussels. Pop. (1926) 5,891. Noyon is built at the foot and on the slopes of a hill.

Noyon, the ancient Noviomagus Veromanduorum, was christianized by St. Quentin at the end of the 3rd century; and about 530 St. Medard, bishop of the district of Vermandois, transferred his see thither from St. Quentin. St. Eligius was bishop in the 7th century, Pepin le bref was crowned here in 752 and his infant son Carloman was then crowned king of Noyon, Charlemagne was crowned here in 768 and Hugh Capet elected in 987. Till the Revolution the bishopric was one of the ecclesiastical peerages of the kingdom. At the beginning of the 12th century Noyon obtained a communal charter through the favour of its bishops. Towards the middle of the 12th century the diocese of Tournai was split off. Noyon was ravaged by the English and the Burgundians during the Hundred Years' War. The city was captured by the Spaniards in 1552, and by the Leaguers, who were expelled in 1594 by Henry IV. John Calvin was born here in 1509.

Noyon was occupied by the German army in 1914 and was abandoned, bombarded and reduced to ruins 1917-18. Its beautiful transitional Romanesque Gothic cathedral was burned, and so was the old *hôtel-de-ville*. A good deal of the stone work of the cathedral survived the fire and it is being restored, the work on the chapter house being now (1928) practically completed. The town has good trade in live stock and grain and contains chemical and artificial manure works and iron foundries.

NUBA, THE. The Nuba may be regarded as the negro or negroid aborigines of Kordofan, although at the present day the northern half of this area is inhabited by Arabic-speaking tribes professing Islam, so that Dar Nuba, the country of the Nuba, occupies only the southern half of the administrative province, extending over 2½° to 10° N.

One of the most remarkable features of Dar Nuba is the multiplicity of languages spoken within its bounds. The inhabitants of hills only a few miles apart may speak languages mutually unintelligible, and even on the same *massif*, there may be two or three communities speaking different languages and coming little in contact with one another, though their customs and beliefs are fundamentally the same.

The inhabitants of the hills of southern Kordofan situated but little north of the Bahr-el-Ghazal have a series of languages with grammatical structure and vocabularies differing substantially from the Berberine dialects. The resemblances noted between the latter and those of Kordofan apply only to those spoken by a limited number of northern communities which have been subjected to foreign, i.e. Berberine, influence for a considerable period. Moreover, as Meinhof points out, such "Nubian" or "Hamitoid" languages extend scarcely a hundred miles south of El Obeid. Further south in the territory recognized by the Arabs as the true home of the Nuba (Dar Nuba corresponding on the administrative side roughly to the Jebel sub-province) two groups of languages must be recognized. One includes a number of "Sudan" languages, the other a series of tongues, called by Meinhof "pre-Hamitic," which, in some respects, resemble Bantu and Fulani and which Struck now terms "Bantoid." These latter languages, first noted in 1910, differ from the Berberine dialects, in which grammatical changes in both nouns and verbs are produced by suffixes, in that in the Bantoid languages these are brought about by initial change.

Struck, who has also studied the Nuba physical material available from the standpoint of its distribution among the linguistic groups considers that each is to be distinguished physically, and although the small number of individuals measured belonging to the Nubian and Sudanic groups renders some of Struck's conclusions premature it is probably true to say that the Bantoid group, with an average stature of 68in. and a cephalic index of 76.5, is rather longer headed and narrower nosed than the Sudanic who are themselves rounder-headed than the Nubian-speaking group from whom they do not substantially differ in breadth of nose or face.

Mode of Life.—The Nuba are for the most part agriculturists, the regulation of public life in each community being ultimately in the hands of the rainmaker. There is no clan organization among the southern Nuba and no restrictions upon marriage other than those imposed by blood relationship. No bride-price is paid, and either party can break the marriage at pleasure; property passes in the female line. This applies especially to the southern communities speaking Bantoid languages; further north, where a bride-price is paid, matters are less simple. Neither circumcision nor infibulation is practised, but the women of Jebel Talodi and the hills round it perforate the lower lip, in which they wear a quartz ornament. On many hills, especially where the lip ornament is worn, the lower incisors are removed in both sexes.

Darfur.—The non-Arab races of Darfur belong ethnically to, or originated from (many are now mixed) the hill stock, spoken of in Kordofan as Nuba (*supra*). In the north are the Bedayat, a nomad people related to Zaghawa; to the north of these are the Kura'an, who have been identified with the ancient Garamantes. The Zaghawa to the south are mentioned by Mas'udi, while Ibn Khaldun speaks of them as living further east, and at the present day there is a colony of them at Jebel Kagmar in Kordofan. These folk, although Mohammedans, have not yet given themselves Arab pedigrees; they retain their belief in rain-makers and are noted as potters. The people of Jebel Midob about 400m. west of Khartoum, described by MacMichael, differ but little from the Nuba of Kordofan; they are perhaps the least unknown of the pagan tribes of Darfur. The Tungur and Dargu are other ancient peoples of Darfur, the latter living by cultivation and breeding cattle in the fertile areas to the west of Dara. None of these peoples are as important as the Fur, from whom the country takes its name. Their stronghold is or was the considerable range known as Jebel Marra, whence they descended probably in the 17th century. Now nominally Mohammedans they still worship stones or trees to the extent that certain spots associated with rocks or trees are regarded as holy and are the scenes of sacrifice. (C. G. S.)

NUBAR PASHA (1825-1899), Egyptian statesman, was born at Smyrna in January 1825, the son of an Armenian merchant named Moghreditch, who had married a relative of Boghos Bey, an influential minister of Mehemet Ali. He was educated at Vevey and by the Jesuits at Toulouse. After some eighteen

months' training as secretary to Boghos, who was then minister of both commerce and foreign affairs, he was made second secretary to Mehemet Ali. In 1845 he became first secretary to Ibrahim Pasha, the heir apparent, and accompanied him on a special mission to Europe. Abbas Pasha, who succeeded Ibrahim in 1848, maintained Nubar in the same capacity, and sent him in 1850 to London as his representative to resist the pretensions of the sultan, who was seeking to evade the conditions of the treaty under which Egypt was secured to the family of Mehemet Ali. Here he was so completely successful that he was made a bey; in 1853 he was sent to Vienna on a similar mission, and remained there until the death of Abbas in July 1854. The new viceroy, Said, at once dismissed him from office, but two years afterwards appointed him his chief secretary, and later gave him charge of the important transport service through Egypt to India. Here Nubar was mainly instrumental in the completion of railway communication between Cairo and Suez. After a second time falling a victim to Said's caprice and being dismissed, he was again sent to Vienna, and returned as principal secretary to Said, a position he held till Said's death in January 1863.

On the accession of Ismail Pasha, Nubar Bey was in the prime of life. He was already on friendly terms with Ismail; he even claimed to have saved his life—at all events, it was a coincidence that the two had together refused to travel by the train the accident to which caused the death (on May 14, 1858) of the prince Ahmed, who would otherwise have succeeded Said. Ismail charged him with a mission to Constantinople, to notify his accession, and to smooth the way for various projects, notably the completion of the Suez Canal, the change in title to that of khedive and the change in the order of succession. The sultan, believing as little as every one else that the canal was anything more than a dream, gave his consent at a price the moderation of which he must afterwards have regretted. The gratified Ismail created Nubar a pasha, and the sultan himself, persuaded to visit Cairo, confirmed the title so rarely accorded to a Christian. Nubar was sent to Paris to complete the arrangements, and to settle the differences between Egypt and the Canal Company.

On his return Nubar created the department of public works; but in 1866 he was made minister of foreign affairs, and at once went on a special mission to Constantinople, where he obtained the sultan's consent to the adoption by Ismail of the title of Khedive and the change in the law of succession. Nubar now had a harder task to undertake than ever before. The antiquated system of "capitulations" which had existed in the Ottoman empire since the 15th century had grown in Egypt to be a practical creation of seventeen *imperia in imperio*. (See *EGYPT: History*.) That in spite of the jealousies of all the powers, in spite of the opposition of the Porte, he should have succeeded in replacing the seventeen consular courts by mixed international courts with a uniform code, puts him in the first rank of statesmen of his period.

The extravagant administration of Ismail, for which perhaps Nubar can hardly be held wholly responsible, had brought Egypt to the verge of bankruptcy, and Ismail's disregard of the judgments of the Court at last compelled Great Britain and France to interfere. Under pressure, Ismail, who began to regret the establishment of the International Courts, assented to a mixed ministry under Nubar, with Rivers Wilson as minister of finance and de Blignières as minister of public works. Nubar, finding himself supported by both Great Britain and France, tried to reduce Ismail to the position of a constitutional monarch, but he lost the support of Great Britain and France, and was dismissed. (See *ISMAIL*.) Nubar remained out of office until 1884, when he was induced to become premier as the instrument of British policy, but he presently found himself in disagreement with Lord Cromer, and was dismissed by the khedive Tewfik in 1888.

Riaz Pasha, who succeeded him, was, with one interval of eight months, prime minister until April 1894, when Nubar returned to office. By that time Cromer had more completely grasped the reins of administration as well as of government, and Nubar had realized more clearly the rôle which an Egyptian minister was called on to play: Lord Cromer was the real ruler of Egypt, and

the death of Tewfik in 1890 had necessitated a more open exercise of British authority. In 1895 Nubar completed his fifty years of service, and retired. He died in Paris in January 1899.

NUBIA, a region of north-east Africa, bounded by Egypt, the Red sea and the Libyan desert, and extending south indefinitely to about Khartoum. It includes the Nile valley from Aswan near the first cataract to the confluence of the White and Blue Niles, stretching for about 560 m. between 16° and 24° N. Nubia, however, has no strictly defined limits, and is little more than a geographical expression. It is first associated historically, with the Nobatae, a negro people removed by Diocletian from Kharga oasis to the Nile valley above Egypt, whence the Blemmyes had been driven eastwards. From Nūba, the Arabic form of the name of this people, comes the modern Nubia.

The country consists mainly of sandy desert and rugged and arid steppes and plateaux through which flows the Nile. In this section of the river there occurs a continuous series of slight falls and rapids, and between Khartoum and Philae it makes a great S shaped bend, the region west of the Nile within the lower bend being the Bayuda Desert, and that east of the Nile the Nubian Desert, which districts roughly correspond to the conventional divisions of Upper and Lower Nubia respectively. Most of Nubia is within the almost rainless zone. An auriferous district lies between the Nile and the Red Sea, in 22° N. Politically the whole of Nubia is now included either in Egypt or the Anglo-Egyptian Sudan and has no administrative existence.

The life and agriculture of Egypt and the Sudan depend upon the Nile, which, for a great part of its course, flows through Nubia. To make irrigation possible in Egyptian territory a dam was constructed at Aswan, and barrages at Esna, Asyut and Zifta. Until 1919 the Nile waters were utilized solely by Egypt, but in that year the Sudan Government commenced a scheme to irrigate part of the Great Gezira plain by an enormous dam across the Blue Nile at Sennar, above Makwar, which was completed in 1925, when irrigation commenced and 300,000 feddans of land were irrigated. The cotton produced in this area is estimated at 40,000,000 lb. of lint. A barrage is in course of erection at Jabal Awliya (Gebel Aulia) about 35 m. south of Khartoum on the White Nile. Work was suspended in 1921 but recommenced in 1925.

Proposals have also been put forward to build a dam at the foot of Lake Albert in Uganda territory, to put a second dam across the Upper Blue Nile above the Sennar dam and also to erect a barrage at Nagh Hamadi in Egypt. The Government of Egypt naturally watches very closely the construction of irrigation works in the upper reaches of the Nile, so that the whole irrigation problem of the Nile bristles with economic, and unfortunately, political difficulties which have more than once assumed a very serious character. The construction of barrage works at Lake Tsana, in Abyssinia, has been suggested for the purpose of regulating and increasing the flow of water down the Blue Nile. This has led to a political controversy between Great Britain, Italy and Abyssinia. Attention has also been directed to the river Gash for irrigation purposes.

Linked up with the problem of irrigation is that of communication in this region. The railway from Alexandria and Cairo terminates at Aswan. The Nubian portion of the Nile is served by rail from Wadi Halfa via Berber, Khartoum to Sennar, with branches from the north of Abu Hamed to Merowi, from Sennar to El Obeid crossing the White Nile at Kost, and from Berber eastwards to the Red sea at Port Sudan and Suakin. From Haiza Junction on the latter section a branch passes southwards to Kassala and it is proposed to continue it to Sennar. (X.)

ARCHAEOLOGY

The archaeology of Nubia begins with a rare palaeolithic (Acheulian) implement of white quartz from Faras below the Second Cataract. Prehistoric settlements of the copper age spreading from Upper Egypt reached Dakkeh in the early period and held an isolated post at the Second Cataract in the later period. About the time of the 1st dynasty the two cataracts and all the intervening valley were occupied by small communities with the same culture as their Egyptian neighbours, but with two distinct

features in the grave deposits—the best pottery is soft but very thin with brilliant black polish inside, the outside yellow brown variegated with red haematite, and the palettes are of local quartz instead of slate. This culture seems to have soon disappeared. The Pharaohs of the 5th and 6th dynasty sent exploring and trading parties through Nubia and drew contingents for their armies from the Wawat, Aam, Meza and other tribes; but except some fortresses and an advanced trading post at Kerma beyond the Third Cataract they have left little trace. After the fall of the Old Kingdom a native civilization (known as the C-group) sprang up and long flourished between the first two cataracts. No dwellings of these nomad pastoral people have been recognized; they buried their dead in pits beneath orderly circular heaps of stones in the desert at some distance from the river. They used much leather, their black or red polished bowls are decorated with elaborate strap-work or plaited patterns, sometimes intensified by filling with white or with red, yellow and green earths; they made also the "prehistoric" sort of haematitic polished black-mouthed and other kinds of ware. Wawat of the valley and Meza (Beja, Blemmyes of the eastern desert?) alone were then the mercenary soldier tribes. The mother of Amenemhe I., founder of the 12th dynasty, was a Nubian and it is likely that these C-group people were on excellent terms with Egypt throughout that dynasty, whereas beyond the Second Cataract "Cush" appears as the object of conquest, and a series of elaborate fortresses was built all through the cataract region, each with its temple, up to Kerma, the residence of a wealthy Egyptian governor, who imported Egyptian statuary and manufactures and skilled workmen, and developed native-coloured industries in pottery, glazed-ware, etc. The Egyptian governors, and the native kings who succeeded them after the fall of the 12th dynasty, were interred in huge tumuli with multitudes of slaves and retainers buried alive in native fashion. The dead were laid on beds with their daggers, spears and knives; ostrich feathers and figures cut out of sheets of mica adorned the persons of the chiefs; exquisite haematitic pottery abounds, highly polished with grey and orange line between the black top and the red. Kerma was a great city in the midst of a barbarous and benighted kingdom of Cush (very different from the uniform wide-spread C-group), and only isolated burials of the same character generally associated with Egyptians, are found throughout Lower Nubia and Egypt.

Amasis I., his brother and founder of the 18th dynasty, began or added to the temple of Buhon, near Halfa, and in the next reign the Cushite kingdom was crushed out of existence. The first viceroy of the whole region was appointed by Thutmosi I. and entitled "king's son," a title which was afterwards changed to "king's son of Cush" or perhaps "son of the king of Cush," and the southern outpost of the empire was established by Thutmosi III. at Napata. Every king of the 18th dynasty built one or more temples in Nubia or had a shrine cut for him in the rock by his viceroy, and some kings built many temples. The most splendid was that of Soleb dedicated to himself and Ammon by Amenhotep III., who also built a lesser one at Sedēnga to the divinity of his queen, Taia; its name Ha-taia survives to this day in the place-name Adai. The series continued under Seti I. and Rameses II. in the 19th dynasty. The latter is everywhere between the first two cataracts. His new temples and shrines include the two great temples at Abusimbel to himself and Queen Nefertari, also Gerf Husēn, Beit el-Weli, Wadi Sabu'a, Dirr, Ibrim, Faras, Aksha; and like Seti I. he was active in far off Napata. After Rameses II. only modest stelae or graffiti are found; even these cease at the end of the 20th dynasty. By the time that Thutmosi III. established his empire, Nubia had no independent vigour left, and even the C-group people had faded away to nothing. The antiquities of Nubia under the New Kingdom, both large and small, are entirely Egyptian. They include at Anibe tombs built with pyramidal roofs like those of Deir el-Medineh. The land between the First and Second Cataracts, i.e., apparently the region named Wawat, was divided into districts like the nomes of Egypt with separate rulers. The first was centred at Dakkeh (Baki), the second at Anibeh (Maam), and the third opposite Halfa (Buhon), the capital in each case apparently at the southern end of its

district. Each was presided over by a Horus-divinity, representing the power of Pharaoh and dating back to the 12th dynasty, when strong fortresses existed at each of these places. There were also smaller districts subject to Hathor-goddesses, Bigeh to Hathor of Senemt, and Faras to Hathor of Ibshek, whereas in the old Kingdom we hear only of a god Dedun of aromatic Nubia. In the shrines built further south in the New Kingdom the gods of the empire naturally take the lead—Amen-rê of Thebes, Harmachis of Heliopolis and Ptah of Memphis.

The chiefs of Libyan mercenaries in Egyptian pay founded princely families at the southern outpost at Napata. The earliest of the Ethiopian-Libyan princes was buried at Kurrû with his flint-tipped arrows. A few generations later, about 725 B.C., Pankhy, after extending his power over Upper Egypt, triumphed completely over Tefnakhte of Sais. With artisans brought from Egypt Pankhy added to and adorned the temple of Ammon at Napata. The conquest of Egypt by Shabako followed and the throne of the Pharaohs was occupied for about 50 years by Ethiopians. Under the first two, Shabako and Shebitku, building proceeded in Egypt, but in Nubia their only monuments are pyramids in the ancestral burial place at Kurrû. The third Pharaoh, Tirhaqa, built more than one temple at Napata and the first and by far the largest pyramid of a new group at Nûri; at Sanam opposite Napata he built a temple and the extensive cemetery has many relics of his reign. Even in Lower Nubia, at Buhon and at Ibrim, Tirhaqa's name occurs on temple-constructions and isolated graves have been found of his time. When his nephew, Tandamane, retired from Egypt before Psammetichus I. the line of Ethiopian kings continued to reign at Napata, with a palace also at Meroe, and were buried at Nûri. But their borrowed Egyptian culture fell lower and lower. Their sculptures and inscriptions, their glazed amulets and ushabti became ever more barbarous; mummification was abandoned and crouched burial, hand-made pottery (some of it reminiscent of prehistoric black-mouthed ware) became the rule. The pyramids lost their enduring form and sacrificed solidity to height. In Lower Nubia the only records of this time are graffiti of the Greek and Syrian mercenaries of Psammetichus II. (594–589 B.C.) on the colossus of Abusimbel, which must fall in the reign of Aspelta according to Reisner's chronology. The Persians are said to have invaded Ethiopia under Cambyses in 522, but they left no mark, and Ethiopians served in the army of Xerxes. According to Dr. Reisner, Meroe became the chief capital of the Ethiopians about 300 B.C.

At length, towards the end of the 3rd century, Ergamenes, a contemporary of Philadelphus who broke the political power of the priests at Napata, and certainly built his pyramid at Meroe, seems to have joined with Philopator (Ptolemy IV.) in adding to the temple of Isis at Philae and founding a new shrine of Thoth at Dakkeh; Azakheramani, succeeding him, built a shrine at Debod and gave aid to the rebel native kings of Thebes, Harmakhis and Ankhmakhis, until they were suppressed by Epiphanes (Ptolemy V.). The Triacotaschoenus between the first two cataracts was now claimed by the Ptolemies, but nothing was done there after Euergetes II., and his activity was probably confined to the Dodecaschoenus, the southern end of which at Dakkeh commanded the route to the gold mines of the Wadi Allâgi. The natives of Nubia, subject to Meroe, were beginning to acquire wealth and culture and had pushed up, chiefly on the west bank, to the frontier of the Dodecaschoenus.

UNDER AUGUSTUS

After the conquest of Egypt by Augustus the first prefect appointed or agreed to a native ruler for the Triacotaschoenus, but while the next prefect was engaged in Arabia, an army under the command of the Meroitic crown-prince, Akinirar, in the reign of Teriteqas and Amenirenas-Candace, attacked and captured Philae, Syene and Elephantine, and established itself at Dakkeh (Pselcis). Petronius, however, the third prefect, quickly captured their headquarters, almost annihilating the Meroitic army, and following up the Nile, reached Napata and destroyed it. After a Roman garrison had held Ibrim for several months Augustus decided to limit the possessions of the empire above Syene to

the Dodecaschoenus, and soon temple-building began again in this Roman territory all along the west bank, the east bank being more open to attack from the Blemmyes of the desert. The punitive expedition of Petronius had been disastrous for the Meroites from Napata northward, and two centuries who spied out Ethiopia for Nero found nothing but scattered villages and a very impoverished people. Prosperity returned, and in the reign of Natakamani and his queen Amanitère Candace a temple was built at Amâra between the Second and Third Cataract; the Napata temple was restored and important buildings were erected in the far south at Nâga and Ben-nâga and Meroe itself, towards the end of the 1st century A.D. The Faras cemetery, a type of many others, now becomes full of graves with decorated wheel-made pottery in abundance, vessels of bronze and glass, bead necklaces and trinkets, indicating a large and prosperous community. Many of the objects were imported; much is childish or in bad taste, but some of the local pottery is handsome in shape and decoration and much, such as the well-preserved barbotine cups, is of archaeological interest. The traditional hand-made wares (except black topped red ware) also recur. A century later the pottery is all wheel-made but less varied and interesting though still quite characteristic. Dating from A.D. 252 is a very long inscription in demotic writing at Philae recording a religious mission sent to the temple by King Teqreramani, whose monuments are amongst the latest found at Meroe. During all this time the Dodecaschoenus remained outside the Meroitic rule, and its antiquities are of Late Roman style and totally distinct from the Meroitic series on the other side of the border line. Soon after this date the Meroitic culture in Lower Nubia was destroyed by the Blemmyes of the eastern desert who from time to time laid waste Upper Egypt. About A.D. 285 Diocletian withdrew the garrisons from the Dodecaschoenus and invited the Nobadae from the western desert to settle there, subsidising them as a protection against the Blemmyes. The remnants of Meroitic civilization in the south were wiped out early in the 4th century by Aëizanes the powerful king of Axum. The Blemmyes were now established in the valley of the Dodecaschoenus and as far up the Nile as Ibrim and their king reigned at Talmis (Kalabsheh). In the middle of the next century the Nobadae united with the Blemmyes in fresh outrages on Egypt; they were compelled by Flavius in 452 to keep the peace for a hundred years but were allowed to visit the temple of Philae and borrow the statue of Isis for consultation in their own country. About the end of that century Silco, king of the Nobadae, conquered the Blemmyes from Ibrim to the First Cataract. We next discern at least five peoples in Nubia; the Nobadae in the valley between the two cataracts with capital probably Pachoras; the Blemmyes in the eastern desert; the Makurians (perhaps the old Magabari) south of the Nobadae, with capital perhaps at Dongola; and the kingdom of 'Alwa (Alodia) with capital 'Alwa or Sôba on the Blue Nile near Khartoum. In A.D. 543 the pagan temple of Philae was definitely closed and the statues then taken to Constantinople. A Christian missionary, Julian, of the Monophysite creed, with Theodore the bishop of Philae, began the conversion of the Nobadae, and after an interval of 18 years the conversion was consolidated by Longinus, another Monophysite, from 569 onwards. At about that time, under a king Eirpanome, the temple of Debod was converted into a church. In 580 Bishop Longinus accepted the invitation of the king of 'Alwa and was escorted by the friendly Blemmyes through the deserts to the Blue Nile; 'Alwa at once became Christian, although the intervening Makuria remained stoutly pagan for a time.

Little is known of the history of Christian Nubia. For a century Lower Nubia probably enjoyed peace and prosperity. Makuria and Nobadia uniting in one Christian kingdom ruled from Dongola. In 652 a Muslim army from Egypt under 'Abdallah-ibn Sa'ad captured Dongola, and required all the inhabitants of the kingdom to pay tribute to Egypt. Arabic historians often refer to the dealings of Egypt with Nubia, and the names of many kings are known from literary sources or from monuments, some of them being native as the above Eirpanome and Kudanbes (A.D. 1320), others biblical, as David, Abram, others again Christian-Greek as Basil, Mercurius.

The churches in Nubia were singularly small, when not simply adaptations of heathen temples or parts of them, or of tomb-grotoes. The more pretentious were built with carved stone columns and lintels, the walls of stone up to the level of the windows and above that of crude brick; others were entirely of crude brick, for which material in the more rainy districts of the south burnt brick was substituted. Many bear the marks of Muslim ruin and progressively inferior repair, with inappropriate re-use of the carved stones. There were two principal types, basilican and domed. The apse was single with altar in front and a sacristy on either side; the nave was with aisles, the ambo on the north side of the nave, a chamber at the north-west corner and a stairway to the roof at the south-west corner. Painted figures of Christ, saints and angels, and scenes from the Old and New Testaments covered a large part of the walls. Little now remains of them, much having been ruined in the last hundred years, not only by the natives, but by archaeologists clearing away without record all Christian work from the temples. Pottery was, as always in Nubia, the best product of the arts, the most attractive sort being shallow cups of fine thin ware coated with a thick white slip and painted in various designs in sepia.

NUBIAN LANGUAGE AND WRITING. Nubian is the name given to the language of the Barabra or Nubians in the Nile valley, between Merawi, a few miles below the ancient Napata, and the First Cataract at Aswān. It has here two principal dialects, the Mahass-Fadija being spoken in the central portion, from a little south of the Third Cataract, and the Dongola-Kenzi at either end of the region; the speech of these Barabra is now pervaded with Arabic words. Moreover, in the hills of Kordofān, dialects of Nubian are spoken by many small communities amongst other languages only remotely akin, and are found westward as far as eastern Darfūr. Nubian is without gender, agglutinative and mainly monosyllabic. Nubian roots are traceable in Ethiopian geographical names handed down by classical authors; but perhaps the chief interest of the language is its use in the writings of the Nubian Church. Probably to fortify their independence against Muslim encroachment, the Nubians adapted the Greek alphabet, with necessary additions from the Coptic and perhaps the Meroitic alphabets, to the purpose of writing their own language. The rare examples of Nubian writing that have been discovered, besides graffiti and two legal documents, comprise portions of a lectionary, homilies and edifying narratives, obviously translated from Greek and not from Coptic. The earliest dates from the end of the 8th century, the latest from the beginning of the 14th.

NUBIANS: see BARABRA.

ÑUBLE, a province of central Chile, bounded on the north by Maule, east by the Argentine Republic, south by Concepción and west by Concepción and the Pacific ocean. Area, 4,592 sq. m. including the *departamento* of Itata added in 1928; pop. (1920) 210,763 including that of Itata. The province lies partly in the great central valley of Chile, noted for its fine climate and fertility, and partly on the western slopes of the Andes. The Itata river, which forms the southern boundary, and its principal tributary, the Nuble, form the drainage system of the province. Agriculture

and grazing are the principal industries. Wheat is largely produced, and there are vineyards in some localities. Stock-raising is pursued in the east. The State railway from Santiago to the southern provinces passes through Nuble, from north-north-east to south-south-west, and sends off a branch from Bulnes west to Tomé on the Bay of Concepción. The capital is Chillán, pop. (1920) 30,881, and the only other important town is Bulnes. The hot baths of Chillán, in the eastern part of the province on the slope of the volcano of that name, are very popular in Chile.

NUCERIA, an ancient city, Magna Graecia, on the west coast of Italy near the modern Nocera Tirinese. It was a small city in an important strategic position between two rivers, the valley of one of which affords a route to the valley of the Crathis, but had no harbour.

NUCLEUS, in biology the term first introduced by Miescher (1871), employed to describe a structure found in the cells of which the tissues of animals and plants are composed. In general it is a viscous spherical body containing a structure known as the *plasmosome* (or *nucleolus*) and a tangle of material *chromatin* characterised by a special affinity for basic dyes. The importance of the latter is set forth in the article on *CYTOLOGY* (q.v.). Discrete nuclear structures can be found in many micro-organisms, but cannot be identified with certainty, as yet, in the living substance of bacteria and *Cyanophyceae* (blue-green algae).

(L. T. H.)

NUCLEUS. Modern physical research has led to the theory that an atom of any given element, far from being the minute, impenetrable solid entity which it was supposed to be before, the discovery of the electron, is a very open structure. It consists of a small, relatively compact particle at the centre, carrying a net positive charge, which is surrounded by a number of electrons sufficient to make the atom, as a whole, neutral. This central particle, in which practically the whole mass of the atom is concentrated, is exceedingly small, even compared to the atom. It is about a million-millionth of a centimetre in diameter, while the atom itself is a few hundred millionths of a centimetre across. These figures must not be taken to do more than give a rough estimate of the kind of sizes in question, for not only is it difficult to define precisely the size of a particle without a sharp boundary, such as an atom or its parts, but also the size is known to vary somewhat from atom to atom. The minute central particle is called the nucleus of the atom, the term having been first suggested by Rutherford in 1912 (*Philosophical Magazine*, xxiv, 461), to whom the nuclear theory owes its origin.

The nuclear theory of the atom is discussed under *ATOM*, where, however, attention is directed mainly to the widely-spaced electrons which surround the nucleus, the nucleus itself being considered merely as supplying a central attractive force which governs the number and behaviour of these electrons. In this article the properties of the nucleus itself will be treated in more detail.

Nuclear Properties.—The nucleus being at the centre of the atom, and surrounded by a strong electric field, is inaccessible to ordinary laboratory agencies, such as heat, strong electric or magnetic fields, mechanical pressure, and so on. Chemical combination affects only the outer regions of the atom, and has no influence on the nucleus itself. Nuclear properties are therefore atomic properties, rather than molecular properties: that is, they persist unchanged as properties of the atom, no matter how it may be combined. Such a property is mass, which has been experimentally shown, to a very high degree of accuracy, to be unchanged by chemical reactions. Another property of the nucleus is its net positive charge, which determines how many electrons an atom can possess in its neutral state, and so determines its chemical properties, since a given number of electrons controlled by a given central charge take up a definite disposition. To these mass and charge properties of the nucleus we attribute the existence of isotopes (q.v.), since, as we shall see, a given nuclear charge is not invariably associated with the same nuclear mass. The radioactive properties, which no laboratory agent can produce or modify, hurry up, or slow down, are also of an atomic nature. There is strong evidence that the radioactive processes which give rise to the discharge of α -, β -, and γ -rays arise in the

nucleus: radioactivity is a nuclear process. It is, in fact, mainly from the radioactive side that our knowledge of nuclear structure, scanty though it may be, has come.

The experiments, mainly carried out by Aston, which have established firmly the existence of isotopes, reveal the net charge and mass of the nucleus, but tell us little of any mechanism which may exist within the nucleus. We may therefore say that the study of isotopes reveals the static properties of the nucleus. On the other hand radioactive processes arise in energy changes which are taking place within the nucleus. Their study reveals the dynamical aspect of the nucleus.

Origin of the Theory of the Nucleus.—Rutherford was led to enunciate the nuclear theory of the atom as a result of a study of the scattering of α -particles by matter. The α -particles are atoms of helium, carrying a positive charge $2e$ (where e is the magnitude of the electronic charge), which are shot off spontaneously by certain radioactive bodies. (See RADIOACTIVITY.) The α -rays from a given radioactive element are homogeneous in velocity (except for a few longer range particles present in certain cases), and thus provide a very valuable instrument for investigation. Those from Radium C, for instance, which have been chiefly, though not exclusively, used for the scattering experiments, are discharged with a velocity of about 1.922×10^9 cm./sec., and an energy of 1.224×10^{-5} ergs. Swift α -particles can be detected by their action on a phosphorescent screen. If a surface be covered with phosphorescent zinc sulphide, which is the substance usually employed, and the soft glow produced in the sulphide by the near presence of a radioactive substance be examined with a low power microscope, it is found that the light is not uniform, but made up of evanescent specks of light, which are referred to as scintillations. These scintillations are due to the impact of α -rays on the screen. (See RADIOACTIVITY.) With suitable precautions every α -particle can be made to produce a scintillation so long as its energy has not been too much diminished by passage through matter before the impact. A phosphorescent screen placed at right-angles to the path of a pencil of α -rays gives us, then, a method of ascertaining how many α -particles fall in a given time within a given small area, that is, proceed in a given direction, and it is by the scintillation method that the scattering of α -particles has been investigated. A narrow beam of α -rays of homogeneous velocity, say from a source of Radium C, produces a sharp spot on the screen. If a very thin metal foil be introduced in the path of the beam the spot loses its sharp outline and becomes diffuse, and a study of the scintillations makes it possible to say what fraction of the particles has been deflected through a given angle by the passage through the foil.

Studying the scattering in this way Geiger and Marsden found that the distribution of the scattered particles in the neighbourhood of the original beam was such as to accord with the view that each particle had suffered a large number of encounters, each encounter producing a small deflection in a random direction. In other words, the scattering through small angles obeys a law which can be calculated from the theory of probability, applied to calculate the final effect of many scatterings in chance directions. In addition to these α -particles scattered through small angles there are a few scattered through large angles, and among these there are even some that have been so far deflected from their original direction that they issue from the foil on the same side as they went in, being thus, in a sense, "reflected." It might at first be supposed that a large number of small deflections conspire to produce such a very large deflection, but, from the probability considerations that give the distribution for small angle scattering, the number of particles to be anticipated at any given large angle can be calculated, and turns out to be far less than the number of large angle scatterings actually observed. In other words, there are far too many particles scattered through large angles for it to be possible to explain them on the basis of a multiple scattering through small angles in random directions. It was from this apparently insignificant quantitative observation that the nuclear theory sprang.

In 1911 Rutherford pointed out that large angle scatterings of the α -particle, in the number actually observed, could only be

explained as the result of single encounters with very intense centres of force. To provide those centres of force he assumed that each atom contained a central positive charge, with which the mass of the atom was associated, the remainder of the atom being made up of rings of electrons, maintained in a stable position by rotation. The central charge (or nucleus, as it was called later) was assumed to occupy a very small space, the diameter being taken as of the order 10^{-12} cm. in Rutherford's original paper. It becomes clear that in this case very few of the α -particles passing through a thin foil, which may be some thousands of atoms thick, will approach near the nucleus: rather they will pass near outlying electrons in several atoms, experiencing a small deflection at each near passage. This accounts for the distribution of the particles deflected through small angles. An occasional α -particle, however, will pass close to the nucleus, and will then experience, owing to the intense field of force caused by the big positive charge, a deflection which will be the larger the closer the approach. We thus distinguish between two different processes, multiple scattering, which denotes repeated small deflections in the majority of the particles which traverse the foil, and single scattering, which denotes the occasional very large deflection due to passage close to the nucleus. With foils such as are used in the experiment the chance of a given α -particle experiencing more than one close approach to a nucleus, and hence more than one large deflection, is negligibly small.

This theory of single scattering survives severe quantitative tests. With the help of the simple theory of the dynamics of a particle, as applied in elementary considerations of planetary motion, the behaviour of a particle projected towards another particle repelling it with an inverse-square law of force can be easily worked out. Let the mass of the nucleus be so large that it may be considered infinite, and let its charge be Ze , where e is the magnitude of the electronic charge: let the mass, charge and velocity of the α -particle be M , E and v . Then it can be shown that

$$p = \frac{ZeE}{Mv^2} \cot \frac{1}{2}\varphi$$

where p is the length of the perpendicular from the centre of the nucleus onto the original direction of motion, and φ is the angle through which the particle is deviated. (Fig. 1.) This gives a relation which can clearly be used to find the chance of a given large angle of deviation, since the probability of a given p can be found immediately if we know

FIG. 1.—TO ILLUSTRATE THE THEORY OF SINGLE SCATTERING OF PARTICLES BY A HEAVY NUCLEUS

the number of nuclei (i.e., of atoms) per unit area of foil. If n be the number of atoms per unit volume, t the thickness of the scattering foil, the chance q of a particle having an original direction such that p lies between p_1 and p_2 is

$$q = \pi(p_1^2 - p_2^2) nt$$

so that the fraction of the incident particles deviated at an angle between φ_1 and φ_2 is

$$q = \pi \frac{Z^2 e^4 E^2}{M^2 v^4} nt (\cot^2 \frac{1}{2}\varphi_1 - \cot^2 \frac{1}{2}\varphi_2).$$

Since it is usual to arrange the little phosphorescent screen so as to be normal to the particular direction of scattering which is being investigated the equation is usually transformed so as to give the number A of particles turned through a given angle φ which fall per unit of area on such a screen placed at distance r from the point where the original beam hits the foil. This is

$$A = \frac{QntZ^2 e^4 E^2 \csc^2 \frac{1}{2}\varphi}{4r^2 M^2 v^4} \quad (1)$$

when Q is the number of particles in the original beam.

Now this formula can be checked experimentally:

(1) By measuring the number of particles turned through dif-

ferent large angles, to investigate the proportionality to $\text{cosec } 4\frac{1}{2} \phi$.

(2) By investigating the connection between the number scattered at a given fixed angle ϕ and the velocity: the number should be inversely as the fourth power of the velocity.

(3) By varying the thickness of the foil, and measuring the variation of the number of particles scattered at a given fixed angle, which should be proportional to the thickness.

In these points the formula was satisfactorily confirmed. The proportionality to thickness is particularly important. Quite apart from the formula, it is easy to see that the theory of single scattering gives this result, since the number of nuclei behind a given surface area of foil is proportional to the thickness, and the chance that the close approach needed for large angle scattering shall take place with more than one nucleus is negligibly small with the thicknesses of foil which are practicable. On the other hand any theory of multiple scattering gives a proportionality to the square root of the thickness of foil.

To help the reader to form an idea of the chance of a single scattering through a large angle, and of the unlikelihood that a single particle shall make two encounters of the type which lead to such scattering, the following picture may be offered. One of the thicker gold foils used in the scattering experiments, actually some few hundred-thousandths of an inch thick, may be considered to be magnified until it is a mile thick. The centres of the individual gold atoms will then be about a yard apart. The α -particle on the same scale will be represented by a tiny grain of dust, something less than a thousandth of an inch across. To be deflected through 45° this grain, in its passage through the mile-thick foil, must pass within four thousandths of an inch of one of the yard-separated centres. For larger angles of scattering an even closer approach is necessary.

The large angle scattering of α -particles thus afforded, at the hands of Rutherford, certain evidence as to the nuclear structure of the atom. The great advantage of the α -particle as a probe to investigate the fields of force which make up atomic structure is, firstly, that a single radioactive element gives a beam of homogeneous velocity, and, secondly, that single particles can be detected. A great deal of work has been done on the scattering of β -particles, from which a degree of confirmation of these views as to the mechanism of single scattering and multiple scattering can be derived. The intermediate case, where the number of deflections suffered by a particle is neither one, nor very large, also comes into account with β -particles with a certain thickness of foil and a certain angle of scattering. The problem of β -ray scattering, while of considerable interest, has not, however, on the whole, given us any fresh information on the nucleus, and therefore only receives passing reference here. It should not, however, be forgotten that, as a result of experiments on the absorption by matter of electrons of different speeds, including β -rays, Lenard, as long ago as 1903, put forward the view that the impenetrable part of the atom was very small. This impenetrable part, however, he considered to be located in a large number of small electrical doublets, which he called dynamids, each dynamid being, as a whole, electrically neutral. While this view has perforce been abandoned it is of great historical importance.

The Charge and Mass of the Nucleus.—If the elements be arranged in order of atomic weight, and then numbered successively, starting with hydrogen as 1, helium as 2, and so on, the number pertaining to a given element is known as the atomic number, a number often denoted by Z , which symbol is used throughout this article. The charge on the nucleus is then Z times the magnitude of the electronic charge e . That this is so was first suggested by van den Broek in 1913, and confirmation of his hypothesis was speedily furnished by the experiments of Moseley. Moseley used the method of crystal reflection, which had just been discovered by W. H. and W. L. Bragg (see under article X-RAYS), to measure the wave length of the characteristic X-rays given out by different elements subjected to suitable electronic bombardments, and found that the X-ray spectrum of every element conformed to a single type, consisting of a group of a few lines of shorter wave length and another group of a few lines of longer wave length. These groups corresponded to the

so-called K and L radiations discovered by Barkla from the difference of their penetrating power, and were accordingly called the K and the L series.

The K and L radiations are characteristic of the atom, not of the molecule: they are not affected by the state of chemical combination in which the atom may be held (except for certain small secondary effects, discussed under X-rays, Röntgen).

Moseley found that the wave length of a given line in the X-ray spectrum decreased from element to element, taken in order of increasing atomic weight, and also that the frequency of such a line followed a simple law. This law, known as Moseley's Law is that, if corresponding lines be selected in the spectra of the various elements, then the square root of the frequency increases by a constant amount from element to successive element. Now while the atomic number, as defined, increases by 1 from element to element, the atomic weight increases by irregular steps. The law is exhibited in fig. 2, where $\sqrt{\nu/R}$ is plotted above against atomic weight, below against atomic number: it is obvious that regularity exists in the latter case only. Here ν is the frequency of the selected line, in the case of fig. 2 the so-called $K\alpha$ line, and R is the constant, of fundamental importance for the theory of

FROM E. N. DA C. ANDRADE, "STRUCTURE OF THE ATOM" (G. BELL & SONS)

FIG. 2.—THE SQUARE ROOT OF THE FREQUENCY OF AN X-RAY SPECTRAL LINE PLOTTED (ABOVE) AGAINST ATOMIC WEIGHT, AND (BELOW) AGAINST ATOMIC NUMBER, SHOWING THAT A SINGLE RELATION EXISTS IN THE LATTER CASE ONLY

line spectra, known as Rydberg's constant. (See SPECTROSCOPY.) These results clearly show that there is some fundamental feature of the atom which is proportional to the atomic number, but has no reference to the atomic weight. A comparison of the simple formulae found by Moseley for the relationship between the frequency of the X-ray lines and the atomic number Z , which can be written

$$\frac{\nu}{R} = (Z-1)^2 \left(\frac{1}{1^2} - \frac{1}{2^2} \right) \text{ for the } K\alpha \text{ line}$$

and

$$\frac{\nu}{R} = (Z-7.4)^2 \left(\frac{1}{2^2} - \frac{1}{3^2} \right) \text{ for the } L\alpha \text{ line}$$

with the general formula, deduced by Bohr, for a series in the line spectrum of a hydrogen-like atom (see ATOM), namely

$$\frac{\nu}{R} = Z^2 \left(\frac{1}{n'^2} - \frac{1}{n^2} \right)$$

where Ze is the nuclear charge, shows that Moseley's Z , multiplied by e , must also be the nuclear charge. The constants subtracted from Z in Moseley's formula represent, speaking roughly, a shielding effect of the inner electrons. (See X-RAYS.) Thus Moseley's work, as represented by fig. 2, proves that the net positive charge on the nucleus is given by the atomic number, which thus has a fundamental significance for the nuclear theory of the atom. Moseley's linear relation is shown by more recent experiment not to be exact, but the departure, which is in the sense of a slightly more rapid increase of $\sqrt{\nu}$ with increasing Z , does not affect in any way this deduction, the curve remaining smooth, and the deviation from linearity being attributable to secondary effects.

The magnitude of the nuclear charge can be deduced directly from experiment by applying the formula (1) for single scattering, whose verification has already been discussed. A can be experimentally determined, by counting the scintillations due to particles scattered through a given large angle; n is known from the atomic weight and the density; the thickness t of the foil can be easily

measured; e , E , M , v are all known; and r and φ merely express details of the experimental disposition. The only unknown in the equation is therefore Z . Rutherford in his original paper merely made a rough estimate, from which he conjectured that Z was about half the atomic weight, which is, in fact, a fair approximation. In 1920 Chadwick carried out the scattering experiments in a modified form, with greater accuracy, and obtained for platinum, silver, and copper values of Z which were respectively 77.4, 46.3, and 29.3. The atomic numbers of the elements in question are 78, 47, and 29 respectively, so that the hypothesis that the number of electronic charges, of positive sign, in the nucleus is equal to the atomic number has been confirmed by the scattering experiments for elements of widely different atomic number.

The nuclear theory of the atom has been confirmed by another method of studying single scattering. The Wilson cloud chamber (qv) gives us a method of rendering visible the path of an α -particle, by means of a condensation of minute droplets of water on the ions produced by its passage. A study of photographs of these so-called ray tracks shows that some of the tracks end in forks, both prongs of the fork making an angle with the original direction of the α -ray. The one prong is due to the α -particle itself, turned through a large angle by collision with a nucleus of a gas atom, the other prong is due to the struck nucleus, which likewise produces ionisation, and consequent condensation, along its path. A single photograph will not enable us to measure accurately the angle which the forked tracks make with one another and with the original ray, since the plane containing the three paths makes an unknown angle with the direction from which the photograph is taken. If, however, two photographs are taken of a single ray track, from mutually perpendicular directions, it is a simple matter of geometry to find these angles. Now, on the assumption that the collision of α -particles obeys the ordinary laws of mechanics for the collision of perfectly elastic bodies (conservation of energy and momentum) it is easy to calculate a theoretical value for the angles involved in the collision, but such a calculation involves the ratio of the mass of the struck particle to that of the striking particle. Comparison of the theoretical and experimental values enables us to find a value for this ratio. Blackett, from a study of the passage of α -particles through oxygen, obtained in this way for the mass of the oxygen nucleus 16.72, which is in good enough agreement with the chemically known value 16. Examples of his photographs are given in the article WILSON CLOUD CHAMBER. Calculation shows that if the masses of striking and struck particles are equal, a case that can be realized experimentally by letting α -particles pass through helium, the two branches of the fork should always be at right angles to one another, no matter what angle the α -particle itself be turned through. This result has also been confirmed experimentally, the actual value found being, for instance, $89^\circ 27'$ in one case. Since all the calculations are based upon the assumption that the whole mass of the atom is concentrated in a minute nucleus these ray track experiments give a brilliant confirmation of this feature of the theory.

The Size and Field of Force of the Nucleus.—In the case of an entity like the nucleus, whose existence is revealed to us by experiments on the deflection of particles, no definite boundary is defined by the conditions, and we must discuss what we mean by its size before we can attempt to form an estimate of it. Let us first consider what we mean by size in the case of other entities. In the case of an ordinary body, such as a metal wire, we can measure the thickness either by visual methods, such as the use of a reading microscope, depending upon the fact that there is an abrupt change of optical properties at the surface of a metal (revealing itself, for instance, by a reflection of the light taking place at a definite plane) or by mechanical methods, such as a micrometer screw. The reading of the micrometer depends to a slight extent upon how hard we screw it up, or the recorded size of the wire depends upon the force we exert. In other words, what we are really measuring is the place at which the resistance to the jaws changes abruptly, the force being negligibly small just outside the surface, and increasing rapidly but continuously as we force the jaws together. In the case of the dimensions of an atom, as measured by methods depending on the kinetic theory of gases,

the diameter of the atom is taken as the distance between the centres of two atoms at the moment of closest approach. This depends markedly upon the relative speed of the two atoms, decreasing as the speed increases, that is, as the temperature of the gas is raised. The size of the atom usually accepted is that given by the distance of closest approach in a gas at ordinary temperatures, but some other methods, such as the distance of closest approach of atoms in a crystal of known structure, may also be used, and give somewhat different values.

We note the condition of arbitrariness in statements of atomic size: an atom has no sharp boundaries. Similarly, some convention must be adopted in speaking of the size of the nucleus of the atom. Either we can make an attempt to estimate the distance between the centres of the nucleus of an atom and of the α -particle at the moment of closest approach, the α -particle having a given velocity, or we can investigate the distance from the centre at which the inverse-square law of repulsion breaks down. Whether this distance be called the size of the nucleus is a matter of definition, and in any case it becomes necessary to state within what degree of accuracy we require the inverse-square law to be obeyed outside the boundary so specified. As with the atom, what we call the size is, within limits, a convention.

The investigations of the scattering of α -particles, to which extensive reference has already been made, shows that with gold, for instance, the inverse-square law holds in cases where the angle of scattering is anything between 5° and 150° , since the formula (1) is based upon the assumption of an inverse-square law, and it represents experimental fact within this range of angle. For an actual head-on collision, the distance b of closest approach of centres is given by

$$\frac{1}{2} M v^2 = \frac{Z e E}{b}$$

from which b can be calculated, and for an angle of scattering of 150° the distance of closest approach is only slightly greater. This gives 3×10^{-12} cm. as an upper limit for the radius of the gold nucleus. A study of the photographs of the forked ray tracks also enables us to estimate limits within which the inverse-square law holds, and leads to the conclusion that it is still valid for a distance 7×10^{-12} cm. between centres of nucleus and α -particle in the case of argon and 3×10^{-12} cm. in that of air. The dimensions of the helium nucleus are probably smaller than those of the heavier nucleus, so that the general results of these estimates is 3×10^{-12} cm. as the order of nuclear radius, as compared to 2×10^{-8} cm. as the order of atomic radius. It may be added that the approach for the smaller angles at which the scattering law holds indicates that the inverse-square law is still valid at distances as great as $.36 \times 10^{-10}$ cm. for gold, 5×10^{-10} cm. for air and 10^{-9} cms. for argon, or a space surrounding the nucleus of the order 10^{-10} cm. in radius is free from any marked concentration of electrons.

Rutherford has experimentally studied the impact of α -particles on hydrogen nuclei, as further described when the disruption of the nucleus is considered. He comes to the conclusion that, while for very slow α -particles the number of hydrogen nuclei (to which the name protons, suggested by Rutherford, is often applied) knocked forward at different angles agrees with that calculated on the assumption of an inverse-square law of repulsion between the striking and the struck nuclei, with fast α -particles the number thrown directly forward is much larger than is to be anticipated on this basis, a fact which he explains by supposing that at very close approach of α -particles and hydrogen nucleus the α -particle (helium nucleus) behaves as if flattened into a plate-like form, the plane of the plate being normal to the path of the nucleus, or, since the collision in such cases of very close approach is practically "head-on," to the line joining the centres of the two nuclei. This would clearly give a preferential projection of the struck nucleus in the line of motion of the α -particle. Chadwick and Bieler experimented on the direction in which hydrogen nuclei were thrown forward by α -particles, by letting α -particles pass through a thin film of paraffin wax: the fact that the hydrogen atoms are here combined with carbon atoms has no effect on the

behaviour of the nuclei, the forces of chemical binding being negligible compared to those involved in these collisions. Applying Rutherford's line of argument to these experiments, they came to the conclusion that an α -particle behaves in these collisions like an oblate spheroid of semi-axes 8×10^{-13} and 4×10^{-13} cm., the proton being treated as a point charge, on account of its presumably very simple structure.

To investigate in detail the departure of the field of force surrounding a nucleus from the inverse-square law it is clearly necessary to force the α -particle which acts as our probe as close to the nucleus as possible. The energy of the α -particle cannot be made to exceed that offered by the natural radioactive sources, so that two courses are open:

- (1) to investigate the scattering by light elements, where the nuclear charge is low, and so the nuclear field comparatively weak;
- (2) to work with very large angles of scattering, which correspond to intimate approach.

Rutherford and Chadwick therefore examined the scattering by foils of aluminium and magnesium, choosing fixed large angles, namely 135° and 90° . They used α -particles of different energy, obtained from Radium C by the interposition of absorbing screens of various thickness, to vary the distance of approach. They found that the inverse-square law was followed with both these elements for distances of approach greater than 1.5×10^{-12} cm., but that the ratio of the number actually scattered to the number calculated on the inverse-square law rapidly decreased for closer approach, then attained a minimum and increased again. The minimum was found at 7×10^{-13} cm. for magnesium ($Z=12$) and for a slightly greater distance of approach in the case of aluminium ($Z=13$). The closest distance of approach measured was 6×10^{-13} cms. With gold and silver ($Z=79$ and $Z=47$), where the nuclear field is strong, the inverse-square law was obeyed up to the closest distance of approach obtainable, about 3×10^{-12} cm. and 2×10^{-12} cms. respectively. If we may treat in these experiments the α -particle as a point-charge these results can be interpreted to mean that, with the aluminium and magnesium nuclei at any rate, the repulsive force exerted by the nucleus decreases for distances between 15×10^{-13} and 7×10^{-13} cm., but increases again for closer distances, the inverse-square formula being taken as a standard of comparison. A physical explanation can be given by supposing that the outer parts of the nucleus consist of a layer of positive charge, within which is a layer of negative charge; when the α -particle penetrates the positive layer the effective nuclear charge is diminished, but when it goes further and penetrates the negative layer, the effective nuclear charge increases again. This conception receives further reference when the radioactive nuclei are discussed.

These experiments confirm and extend earlier results found with aluminium and magnesium, which indicated that the inverse-square law held to within one per cent or so for distances greater than 3×10^{-12} cm. Speaking generally, then, we may say that the radius of nuclei, apparently not very different for different elements, is of the order 2×10^{-13} cm., in the sense that at this distance there is a rapid change in the law of force, while it is possible to force a proton to within a distance of 4×10^{-13} cm. from the centre of an α -particle.

Very interesting results have been obtained by Rutherford and Chadwick in their recent (1927) experiments on the scattering of α -particles by helium. The difficulty presented by the fact that a gas like helium cannot be obtained in a thin plate was surmounted by the use of diaphragms, which isolated an incident and a scattered pencil of rays in such a way that all particles reaching the phosphorescent screen must have come from a small annulus of the gas. The experiments were complicated by the fact that both scattered particles and struck nuclei are of the same nature, but skilful interpretation of the results allowed definite conclusions to be drawn. It was deduced that, for central collision, departure from the inverse-square law occurs at distances of about 3.5×10^{-13} cm. between the centres, while for glancing collisions (small angles of scattering) the departure occurs at about 14×10^{-13} cm. This indicates a plate-like form for the α -particles, confirming the conclusions reached by Chadwick and Bieler from

an exhaustive study of the collision of the α -particles with hydrogen nuclei.

It does not appear that these results are to be attributed to the departure from the classical laws of mechanics embodied in the new wave-mechanics (see QUANTUM THEORY), but rather that they are best explained on ordinary mechanical principles applied to a field of force departing from the inverse-square. Rutherford has suggested tentatively that the departures have their physical origin in a definite magnetic moment associated with the helium nucleus, which produces a magnetic force becoming prominent at distances of the order of 4×10^{-13} cm. The turning couple due to two such magnetic moments would explain the orientation of the particles during collision. Of course a magnetic moment must be assumed for the proton itself, the moment of the helium nucleus being a resultant of the moments of its components. The introduction of a consideration of magnetic forces, so long neglected in the internal physics of the atom, seems likely to prove fruitful in the future.

We are faced with the paradox that, while the nucleus must, as we shall see, contain electrons (in the case of a heavy element like gold a great many electrons) yet the size of the nucleus is not much larger than that of the electron, for which the diameter is generally given as 4×10^{-13} cm. The size of the electron, however, is far less directly determined than that of the nucleus. The estimate just quoted is based upon the assumption that the mass is entirely electro-magnetic, and is that which is produced by a distribution of the electronic charge throughout the volume of a small sphere. The electromagnetic mass of such a sphere, moving at slow speeds, is

$$m = \frac{4e^2}{5a}$$

where e is the charge in electromagnetic units, and a is the radius. If instead we assume that the charge is spread over the surface of the sphere we have

$$m = \frac{2e^2}{3a}$$

Where so little is known it does not matter which formula we adopt. The assumption of such a formula is our only way of obtaining an estimate of the size of the electron, for there is no way at present known of investigating the field of force round an electron, which is the only really significant thing. The paradox of the approximate equality of electronic and nuclear size is therefore really explained by the fact that little significance can be attached to the value given for the radius of the electron, and we may further say that, whatever the radius of a free electron, the radius of an electron in close combination with other electrons and protons may be quite different.

The Structure of the Nucleus.—The constitution of the nucleus has been the subject of much speculation. The positive charge is ultimately due to the presence in the nucleus of protons, whose mass is that of the hydrogen atom and whose positive charge is 1 in terms of the electronic charge. If these were the only constituents the atomic number of any nucleus should be equal to its mass in terms of hydrogen as 1, but it is well-known that the atomic number—the net positive charge—is always markedly less than this, being usually less than half of the atomic weight. This indicates that the nucleus itself must contain a number of electrons, whose presence diminishes the positive charge, but leaves the mass practically unaltered. The expulsion of β -particles of very high energy might be taken to indicate the presence of such electrons in the nuclei of radioactive elements, but the occurrence of the β -particles by itself would not be convincing, as they might, without further experiments, be supposed to come from the outer parts of the atom, being ejected by a secondary action of nuclear γ -rays. However, it is found that strong β -radiators are transformed to elements whose chemical behaviour indicates a place in the periodic table corresponding to an increase of atomic number by unity, that is, to a gain of one unit of positive charge by the nucleus. This is equivalent to the loss of one electron by the nucleus, so the behaviour of radioactive ele-

ments affords strong evidence for the presence of electrons in the nucleus.

The occurrence of elements of different chemical properties, but the same mass, the so-called isobares (see ISOTOPEs), also indicates a difference of nuclear charge with no difference of nuclear mass, which can be best explained as the effect of a difference in number of electrons in the nucleus. For the addition of an electron to the nucleus will diminish Z by 1, but not appreciably change the mass. The existence of isotopes (*q.v.*) is also easily explained upon the hypothesis that the nucleus is ultimately built up of protons and electrons. Isotopes are elements which have the same chemical properties, that is, the same Z , but different masses. If, to a given nucleus we add n protons and n electrons we do not change the charge, but increase the mass by n units.

It being established that the nucleus consists of protons and electrons, the question arises as to whether any special combinations exist as sub-groups within the nucleus. The expulsion of α -particles by radioactive nuclei suggests that, inside heavy nuclei at any rate, we have particles composed of four protons and two electrons, existing as particularly stable units. The stability of the α -particle is further discussed in the last section of this article. Meitner has further invoked the existence of particles composed of four protons and four electrons to explain certain peculiarities of the transformations of the radioactive families. (See RADIOACTIVITY.) Two of the electrons are assumed to be less firmly attached than the other two, so that the combination is really a neutralised α -particle. When one electron leaves such a neutralised α -particle, the rest is assumed to become unstable, so that a sequence of changes is to be expected, in which two β -ray emissions and one α -ray emission are associated in some order or other. In the general run of the radioactive transformations this does, in fact, occur, as, for example, where Thorium emits an α -particle, changing to Mesothorium I, followed by two β -ray changes, or where Uranium Y is transformed with a β -emission, to be followed by an α and a β change. The branching of the radioactive series (such as follows, for example, the transformation of Radium B), where a β emission is followed either by a β and an α change, or alternatively by an α and a β change (see RADIOACTIVITY) is also explicable on Meitner's hypothesis.

The hypothesis that the nucleus of radioactive atoms contains α -particles, each neutralised by two tightly bound electrons, has also been used by Rutherford to explain the origin of the α -rays. The α -particle, with its double positive charge will be strongly repelled if it once be released from whatever forces may be supposed to bind it in the nucleus. We can calculate the energy with which the particle will leave the atom, supposing it to be all gained by virtue of the work done on it by the nuclear field of force, if we know the distance from the centre of the nucleus at which it starts. Thus the charge on the rest of the nucleus being $Z'e$, while $2e$ is the charge on the α -particle, this energy is

$$\frac{2Z'e^2}{r}$$

which, taking the slowest α -particle, that from Uranium I, with energy 4.07×10^6 electron-volts, gives the value 6.3×10^{-12} cm. for r , and any assumption that the α -particle possesses an initial velocity would lead to an increased value of r . Scattering experiments, however, show that the inverse-square law holds for distances as small as 3×10^{-12} cm., which could not be the case if there were particles with two positive charges in the region of the nucleus indicated by the above estimate. If, however, the α -particles at distances 6×10^{-12} cm. from the centre of the nucleus normally exist in a neutralised state they will have no effect on the scattering, and the two estimates can be reconciled. The electrons which neutralise the α -particles cannot, of course, exist in the kind of outer orbits which they occupy for the neutral helium atom, for there would be no room for them, but must be held in some much more intimate manner. Rutherford's supposition is that the neutral α -satellite, as we may call it, is attracted to the central bulk of the nucleus by the polarisation forces set

up in it by the nuclear field, and that, controlled by these forces, the satellite executes a quantum orbit, something like that of an electron in the outer parts of the atom. (See ATOM.) When the satellite loses, by some unknown mechanism, its two electrons, it is repelled, gaining its final velocity of expulsion in its passage to confines where the nuclear field is negligible. The electrons are retained by the nucleus, and ultimately discharged in β -ray

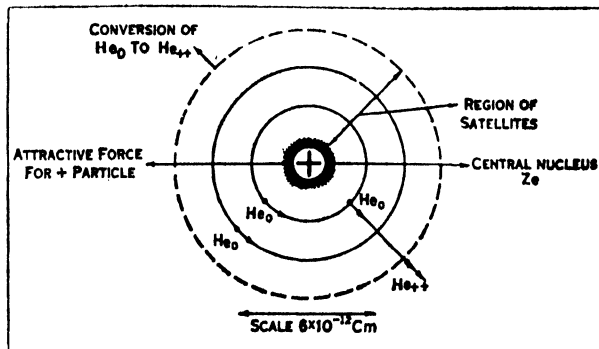

FIG. 3.—RUTHERFORD RADIOACTIVE ATOM

charges. A sketch to illustrate this conception of the radioactive nucleus is given in fig. 3.

The general arguments give us information as to the kind of particles which may be expected to exist within nuclei, at any rate within very heavy nuclei.

A line of argument as to the structure of the radioactive nuclei has been put forward by C. D. Ellis. He has made extensive measurements on the energies of the β -rays liberated from heavy metals by the action of γ -rays from a radioactive substance. (See PHOTOELECTRICITY.) These electrons may be liberated from the K or from the L levels of the atom (see RÖNTGEN RAYS, ATOM) and the study of the X-ray spectra enables us to find the work required to take an electron from any one of these levels to the surface. A comparison of the spectra of the β -rays excited by the same γ -rays in different metals enables us to attribute the origin of certain observed β -rays to certain levels; if we correct the observed energy by adding the work of release, we obtain the same energy for a given β -ray, no matter from which element it has come, or, otherwise expressed, a β -ray spectrum is found which is independent of the element and expresses the energy initially communicated to the β -particle by the incident γ -ray. The quantum theory leads us to believe that the β -particle in these circumstances takes the whole of the energy of the γ -ray which releases it. These observations of the secondary β -ray spectrum therefore serve to reveal the wave length of the incident γ -rays, since the relation between wave length and energy is given by the simple quantum relation.

$$\text{energy} = E = h\nu = h \frac{c}{\lambda}$$

Ellis has thus measured γ -rays of much greater energy, or short wave-length, than those measured by Rutherford and Andrade. Considering the complete γ -ray spectrum of an element, say Radium B, he has found that the different γ -ray energies can be accounted for by assuming a small number of energy levels in the nucleus, quantum transitions between suitably selected pairs of which give the frequency of the γ -rays in the same way as quantum transition between the levels of energy in the outer parts of the atom give rise to spectral lines. (See QUANTUM THEORY.)

We have, then, this evidence for energy levels within the radioactive nuclei, but we do not know to what mechanism these energy levels are to be attributed. It has been supposed that they could be best explained by electron orbits within the nucleus, corresponding to the quantised electron orbits in the outer parts of the atom so much invoked in the explanation of optical line spectra, but Kuhn has criticised this view, and suggested that it is more satisfactory to attribute the energy levels to the suitably quantised movements of massive positive particles.

This part of the subject is in its infancy, and we can say little with any degree of certainty. There is good evidence for a structure of protons and electrons; for a subdivision of the nucleus into energy levels, originating in circulating particles; for the existence of α -particles, and of α -particles neutralised by two electrons, as components of the radioactive nuclei. Beyond this speculation has an untrammelled range.

The Disruption of the Nucleus.—The nuclei of radioactive atoms, which are all heavy and correspondingly complex, are unstable and disrupt spontaneously, giving out either an α - or a β -particle, with a corresponding change in the chemical nature of the atom. The ejection of an α -particle decreases the mass by 4 units and the atomic number by 2 units: the ejection of a β -particle makes practically no difference in the mass, but increases the atomic number by 1 unit. (See RADIOACTIVITY, ISOTOPES.) The lighter elements (with the possible exception of potassium and rubidium) are all stable, and, even after the discovery of radioactivity and the later theory of the nuclear atom, were supposed to be proof against any agencies available in the laboratory. It was known that the outer electrons could be removed by irradiation, or by the impact of particles of sufficient energy, but as long as the nucleus is intact the atom will repair itself by taking up electrons again at the first opportunity. The atom can be *permanently* changed in kind only by adding or subtracting particles from the nucleus, and the expression "breaking the atom" is generally used in popular parlance to indicate such a tampering with the nucleus.

Of recent years Rutherford has shown that we have in the swift α -particle a localisation of energy intense enough to effect a disruption of the nucleus. The experiments are of great importance not only as advancing knowledge of the constitution of the nucleus, but also as the first in which a change in the chemical nature of an atom has been deliberately provoked. (See TRANSMUTATION OF ELEMENTS.)

As a preliminary to the description of Rutherford's method it may be well to consider the impact of an α -particle on a very light nucleus. Whereas in the case of heavy nuclei (the nucleus of a gold or of a silver atom, say) we can neglect the motion of the struck nucleus, in the case of a hydrogen nucleus we must devote special attention to the motion produced by the collision. It is easy to show that the velocity u of the struck nucleus will depend upon the masses M and m of the α -particle and struck nucleus respectively, and upon the angle θ which the path of the nucleus makes with the original path of the α -particle, whose velocity is v . If there is no loss of energy in the collision it is given by the expression:

$$u = 2v \frac{M}{M+m} \cos\theta \quad (2)$$

which becomes $1.6 v \cos\theta$ when the struck nucleus is a proton ($M=4$, $m=1$). It can further be shown that the range of a proton in a given gas is nearly the same as (actually a little less than) that of an α -particle of the same initial velocity, the effect of the reduced mass and of the reduced charge nearly annulling one another in this respect. It is an established result that the range of an α -particle is proportional to the cube of its velocity, whence for a direct impact ($\theta=0$) the range of a struck proton is about $(1.6)^3=4.1$ times the range of the α -particle itself in the same gas. With an α -particle from Radium C, whose range in hydrogen is 31 cm., the range of the proton which it strikes centrally should be 117 cm. in hydrogen. This result makes it possible to distinguish easily between struck protons and α -particles themselves, since the greater range of the former allows them to be detected much further from the source than the latter. It is only the full collisions that lead to so large a range: protons struck at glancing angles have, by equation (2), smaller velocities, and hence smaller ranges. A connection between range and angle can be calculated for equation (2), and this distribution is actually confirmed for slow α -particles. It is a significant observation, however, that for swift α -particles passing through hydrogen far more protons are thrown directly forward than the formula indicates. It was this consideration that first led Rutherford to

assume the plate-like form of the α -particle in close collision, to which reference has been made.

The great range of the light proton struck by the heavier α -particle is the key to Rutherford's first experiments on the disruption of the nucleus. The apparatus used is represented in fig. 4. The brass disc D bears a deposit of radium C, which is the source of the α -particles. This is contained in a brass box

FROM E. N. DA C. ANDRADE, "STRUCTURE OF THE ATOM" (G. BELL & SONS)

FIG. 4.—TO ILLUSTRATE RUTHERFORD'S SUGGESTION AS TO THE CONSTITUTION OF A RADIOACTIVE NUCLEUS

AA which can be exhausted or filled with any gas. An opening S in one end is closed by a thin metal foil, which, as far as its power of stopping α -particles is concerned, is equivalent to about 5 cm. of air. The particles which pass through this foil, and any other foils which may be placed between S and F, produce scintillations on the phosphorescent zinc sulphide screen F. These scintillations are observed with the microscope M. With this apparatus filled with dry hydrogen various results on the range of the struck protons were obtained, of which mention has already been made.

Long-range protons were also obtained from hydrogen compounds, such as paraffin wax in thin films. The particles were identified as protons not only by their range, but also by deflection in an electric and magnetic field. More recently Stetter has also shown that the ratio e/m for the particles knocked out of paraffin wax has the value pertaining to a proton, by using as a source a very thin tube of wax containing radium emanation, and employing an apparatus built on the lines of Aston's mass spectrograph. (See POSITIVE RAYS, ISOTOPES.) The mean of his determinations agrees within 1% with the value to be expected.

When the apparatus of fig. 4 was filled with air, or pure nitrogen (for the effect was soon traced to this gas) particles were observed whose range in air was not less than 28 cm., which is about four times that of the α -particles themselves, or just what we should expect the range of a struck hydrogen nucleus to be. The particles are not due to hydrogen contaminations, such as films of grease, for their number is proportional to the pressure of the nitrogen. Further, when oxygen or oxygen compounds, such as carbon dioxide, are substituted for the nitrogen, nothing but an occasional long-range particle is detected. A large number of control experiments were made, as a result of which it was definitely established that the passage of the α -particles through nitrogen produces particles whose long range gives very strong reason to believe that they must be protons. Rutherford proved that this really was the nature of the particles by deflecting them in a magnetic field.

The only possible source of the long range protons, whose existence is established by these experiments, is the nucleus of the nitrogen atom. We are forced to the belief that the α -particle, when it hits a nitrogen nucleus fair and square, is able to detach from it one of the protons which go to make up its structure, and hurl it in the forward direction. The extreme forward range was later found to be not 28 cm., but 40 cm., which makes the proof of the nuclear origin of the proton even more definite, energy being derived from the nucleus itself. More precise information as to the direction in which the expelled proton proceeds has been furnished by subsequent experiments of Rutherford and Chadwick.

Rutherford and Chadwick have investigated the passage of α -particles through various light elements, with the object of finding out if protons are expelled from their nuclei. (With heavy nuclei this is not to be expected, as the high nuclear charge exerts so large a repulsive force on the α -particle that the close approach necessary to detach a proton cannot occur.) Films of solid compounds of the various metals were placed in the path of the α -particles, and a search made for long-range particles. Such particles were detected with the elements boron, fluorine, neon, sodium, magnesium, aluminium, silicon, phosphorus, sulphur, chlorine, argon, and potassium, as well as the original nitrogen, careful controls in each case establishing that the particles were actually protons, and that their source was the element named. The results obtained with these elements indicate the generalisation that the nuclei of atoms of odd atomic number are more easily broken, at any rate by α -particles, than those of even atomic number, since with the latter the protons, if present at all, are of comparatively short range.

It was found that, whereas, using hydrogen, the free protons are always thrown in the forward direction—a large proportion directly forward—with the other elements the expelled protons proceed in all directions, although the range of the forward ones always exceeds that of the particles proceeding in the backward direction. This indicates that in the mechanism of release of the proton from the nucleus the nuclear forces play a large part: the proton is not just knocked out of a passive nucleus by the passage of the α -particle, as an apple might be knocked from a bough by a tennis racket, but rather the close passage of the α -particle releases some trigger action, the particle being expelled at the expense of nuclear energy. Rutherford and Chadwick have suggested a mechanism in which the expelled proton is assumed to be revolving as a satellite before the expulsion initiated by the α -particle, and the difference of forward and backward velocity is expressed in terms of the path of the struck satellite within the nuclear system before expulsion. Against this Pettersson has put forward what he calls an explosion hypothesis, which supposes that the α -particle starts a disturbance by which the proton is shot out in a random direction with a definite velocity *relative to the nucleus*, which is itself thrown forward. The experimental evidence is insufficient to enable very much to be urged in favour of either hypothesis.

Particular interest attaches to the case of aluminium. The protons expelled in the forward direction from this element have a range of 90 cm. in air, as contrasted with a range of 7 cm. for the α -particles themselves, or 29 cm. for a free proton thrown straight forward by impact of an α -particle. The energy of the long-range proton from aluminium is considerably in excess of that of the α -particle which produces it, involving an actual gain of energy as the result of the collision, independent of the fate of the α -particle. There has in this case been a considerable release of nuclear energy—considerable in relation to amounts of energy involved in the motions of the particles. The actual excess of energy of expelled proton over energy of incident α -particle is, however, only of the order of 5×10^{-6} ergs, so that it would require some ten million million impacts to produce a gain of one calorie. As successful impacts are very rare, the gain of energy is not a matter of immediate practical use.

The fact that the protons are expelled at right angles to the path of the incident α -particles, and also in a retrograde direction, has proved of great service in the investigation of elements for expelled protons. One great difficulty of these experiments is to distinguish between protons due to hydrogen contaminations (either occluded gas or solid or liquid hydrogen compound) and protons originating in complex nuclei. Now whereas the long-range protons from hydrogen contamination are all thrown in a forward direction, those from complex nuclei, released by a trigger action of the passing α -particle, are, on the whole, discharged in much the same numbers in all directions. If, therefore, observations are made at right angles to the path of the incident α -particle, or in a direction making an acute angle (on the side near the source) with the path, the protons observed will be those that originate in the complex nuclei. This method has been used

by Rutherford and Chadwick, and also by Kirsch and Pettersson. As a result Rutherford and Chadwick have given the elements already named as those which show nuclear disintegration under the bombardment of α -particles. They have never found evidence of nuclear disintegration with carbon or beryllium. Kirsch and Pettersson, however, have found protons of 3 cm. range with carbon, and also protons with beryllium, copper, and nickel, using the retrograde method for these elements, and later added to the list ten elements between titanium and iodine. In fact, these workers and their school seem to have seen far more scintillations than other workers, for even in the case of aluminium the number of protons which they give is five times as many as those observed by Rutherford and Chadwick under similar conditions. The discrepancies have not yet been explained. It may be taken as certain that with the elements in Rutherford and Chadwick's list nuclear disintegration can be produced by the bombardment with α -particles, but for other elements final decision must be reserved.

Decisive confirmation of the disruption of the nitrogen nucleus by an α -particle has been supplied by photographs of ray tracks taken with the Wilson Cloud Chamber (*q.v.*). By this method Blackett has taken a very large number of pictures of the passage of α -particles through nitrogen, each picture showing, from two different directions, a bundle of many ray tracks. Altogether 23,000 photographs were taken, showing some 270,000 tracks of α -particles of range 8 and 6 cm. and 145,000 tracks of range 5 cm. from a source of Thorium B+C. As a result 8 tracks were obtained showing the expulsion of a proton, the path of the proton being visible as a long thin beaded track, quite different in appearance from the tracks of an α -particle or struck nucleus. (See Plate I., fig. 6, WILSON CLOUD CHAMBER.) The proportion of α -particles producing disintegration agrees well with Rutherford and Chadwick's estimate from scintillations. Among the eight disruptions recorded one shows a proton ejected backwards, a further confirmation of the scintillation results.

A striking feature of these photographs is that, in the disruption cases, there is no track corresponding to the α -particle *after* collision. This indicates that the α -particle enters into the nucleus and remains there, forming a nucleus of mass $14-1+4=17$, and of nuclear charge $7-1+2=8$. This would be an isotope of oxygen, whose existence has not been detected by the ray spectrograph. (See ISOTOPES.) However, ray-track photographs of Harkins and Ryan, and of Akiyama, taken in air, show, in the case of disintegration, a track of the α -particle after the disrupting collision, indicating that the α -particle does not always stick in the nucleus. The reason for this difference of behaviour is not yet explained.

Stability of Nucleus. Atomic Energy.—The evidence which has been considered clearly shows that the nuclei of all atoms are ultimately built up of electrons and protons in intimate combination. It is clear that combinations containing more than a certain number of these component parts are not stable, for the very heavy nuclei pertain to radioactive atoms, and break up spontaneously. However, of the radioactive nuclei the heaviest are not the most unstable, for Uranium I. and Uranium II., both of atomic number 92, and of atomic weight 238.2 and 234.2 respectively, have very large half-value periods (see RADIOACTIVITY), that is, break down very infrequently, while Actinium C' and Radium C', both of atomic number 84, and of atomic weight 210 and 214 respectively, are extraordinarily unstable. The explanation of the relative instability of the radioactive nuclei in terms of their structure or composition is still to seek. Fajans, however, has enunciated a rule that all nuclei of atomic mass $4n$, where n is a whole number, and of odd nuclear charge, are very unstable. The only radioactive nuclei which fall in this class are those of Thorium C'', Thorium C, and Mesothorium II., which are all β -radiators of comparatively short life. Nuclei of the general composition specified are not found among the other elements, so that the rule, which is purely empirical, does seem to have a general application.

Evidence of relative stability among the nuclei of non-radioactive elements has been sought by Harkins in the comparative

abundance in which different kinds of atoms occur in nature, the assumption being that elements of rare occurrence are comparatively unstable. The commonest elements, both in meteorites, which may be regarded as samples from extra-terrestrial sources, and in the earth, as far as we can judge from geological evidence, are oxygen, silicon, magnesium, and iron, all comparatively light elements of even atomic number. Taking the figures as a whole, elements of even atomic number are much commoner than elements of odd atomic number. Further consideration of the conjunction of atomic weights and atomic numbers in individual elements leads to the conclusions that the number of nuclear electrons is generally even, or nuclear electrons tend to occur in pairs. There are a fair number of empirical rules of this nature, which enunciate generalities, but no laws of universal application. This aspect of the subject still awaits a co-ordinating theory.

The α -particle itself is a particularly stable entity, consisting of four protons and two electrons: the two electrons which it picks up when it becomes a neutral helium atom do not, of course, form any part of the nucleus, but are, relatively speaking, very distant and very loosely held. Evidence of the stability is obtained by consideration of the peculiar fact that, while the mass of the two electrons is negligible, the mass of the helium nucleus is not exactly equal to that of four protons, for the atomic weight of helium in terms of oxygen as 16, is 4.00, while the atomic weight of hydrogen is 1.0077. We might expect the atomic weight of helium to be 4.0308: the difference between this number and the actual number 4.00 is called the *mass defect*.

The explanation of the mass defect is to be sought in the electromagnetic nature of mass. If an electric charge be concentrated in a very small space it requires a force to produce an acceleration of its movement, or, in other words, it possesses inertia. The smaller the volume into which it is crowded, the greater the inertia. Making, for the sake of precision, the very simple, and somewhat improbable, assumption that elementary charges behave as small charged spheres, the electron must have a diameter of 3.8×10^{-13} cm., the proton a diameter of 2×10^{-16} cm. to give the required masses. Even without this assumption we may say, quite generally, that the electromagnetic mass depends not only on the charge but on the capacity of the system. If we bring two small charged spheres of opposite sign close together the capacity of the system is not the sum of that of its parts, considered separately, so that the electromagnetic mass of the two together is less than the sum of the two separately. In general, whenever we pack protons close together with electrons we might anticipate a diminution of mass due to this close packing. The fact that the mass of a nucleus is always less than the mass to be anticipated, by simple addition, from the number of protons it contains is said to be due to the "packing effect." (See ISOTOPES, *Packing Fraction*.)

Quite apart from any mechanism, such as that just considered, we can get an estimate of the stability of the helium nucleus from the mass defect, by taking into account Einstein's relation between mass and energy. (See RELATIVITY.) This relation is

$$m = E/c^2$$

where m is the mass, E the energy, c the velocity of light, which is 3×10^{10} cm./sec. If a system loses mass it loses energy to an amount represented by this formula. For the helium nucleus the energy per gram molecule, i.e., per 4 grams of the gas, is

$$E = .0308 \times 9 \times 10^{20} = .28 \times 10^{20} \text{ ergs} = 7 \times 10^{11} \text{ gram calories.}$$

In the language of the chemist a helium nucleus is an endothermic compound giving out 1.75×10^{11} gram calories per gram when it is formed from four protons and two electrons and similarly requiring this amount of energy to dissociate it back into its component parts. The energy per atom works out to be 4.6×10^{-8} ergs, which is nearly three times the kinetic energy of the swift α -particle, of range 8.6 cm. of air, from Thorium C'. As the swift α -particle represents the greatest localisation of energy at our disposal we may confidently say that the helium nucleus is likely to withstand any agent which we may bring to bear upon it without disrupting.

The enormous energy which, as these calculations show, would be released if we could make hydrogen nuclei combine with electrons to form helium nuclei offers a starting point for daring speculation as to the possibilities of atomic energy, that is, nuclear energy, as a source of power. It may be noted that this is energy which would result from building atoms, not from breaking atoms. The disruption of the aluminium nucleus, with its release of energy, or the spontaneous disruption of the radioactive atoms may be taken as examples of the breaking of atoms with release of energy. If 4 grams, that is one-seventh of an ounce, of helium could be built up from hydrogen we should anticipate a release of nuclear energy equivalent to about a million horse power for an hour. It does not follow that this energy would be released in a form which we know how to handle profitably—it might appear as a very penetrating radiation which would pass through all our screens set to catch it. Speculation has a free range. It has been suggested that a small rate of formation of helium from hydrogen may be responsible for the maintenance of the sun's heat.

The packing effect with heavier nuclei, as represented by the departure of the atomic weights, in terms of oxygen as 16, from whole numbers is a very important study which is being investigated by Aston with a sensitive mass spectrograph. (See ISOTOPES.) His results can be interpreted as supporting the view that the light elements of odd atomic number all have a loosely packed outer structure which has no counterpart in the more stable nuclei. The whole question of the structure of the nucleus, the detailed nature and arrangement of its parts, is still obscure. It is beset with great difficulties, in view of which the progress that is recorded in this article, which deals almost entirely with the work that has been done since 1910, is very encouraging. If at that date the investigation of the composition and structure of a particle some 10^{-12} cms. across had been suggested as a study for the immediate future, few would have taken the matter seriously. (See also TRANSMUTATION OF ELEMENTS.)

NUER: see NILOTES.

NUEVO LEON, a northern State of Mexico. Pop. (1921) 336,412; area 25,136 sq. miles. Nuevo Leon lies partly upon the great Mexican plateau and partly upon its eastern slopes, the Sierra Madre Oriental crossing the State north-west to south-east. A branch of the Sierra Madre extends northward from the vicinity of Salinas, but its elevations are low. The average elevation of the Sierra Madre within the State is slightly under 5,500 feet. The general character of the surface is mountainous, though the western and south-western sections are level. In the north the general elevation is lower, the surface sandy and covered with cactus and mesquite growth. The eastern slopes are well clothed with vegetation, but the lower valleys are subtropical in character and are largely devoted to sugar production. The higher elevations have a dry, temperate, healthy climate. There are many rivers and streams, notably the Salado and Pesqueria.

Agriculture is the principal industry, the chief products being sugar, barley, Indian corn and wheat. Rum is a by-product of the sugar industry, and "mescal" is distilled from the agave. The gathering and preparation of "ixtle" fibres from the agave and yucca forms another important industry, the fibre being sent to Tampico for export. Considerable progress has been made in manufacturing industries, and there are a large number of sugar-mills, cotton factories, woollen mills, important smelting works and iron and steel works. The State is well served with railways. The Mexican National line crosses the northern half of the State and has constructed a branch from Monterrey to Matamoros, and a Belgian line (F. C. de Monterrey al Golfo Mexicano) runs from Tampico north-north-west to Monterrey, and thence westward to Coahuila. The other principal towns, with their population in 1921, are: Linares, or San Felipe (9,810) 112 m. by rail S.E. of

the capital in a rich agricultural region; Montemorelos (6,643); Naranjo (7,704), 96 m. by rail N.W. of the capital; Cadereyta, Jiménez, García, Santiago and Doctor Arroyo.

NUISANCE, that which gives offence or causes annoyance, trouble or injury. In English law nuisance is either public or private. A public or common nuisance is defined by Sir J. F. Stephen as "an act not warranted by law, or an omission to discharge a legal duty, which act or omission obstructs or causes inconvenience or damage to the public in the exercise of rights common to all His Majesty's subjects" (*Digest of the Criminal Law*).

A private nuisance is an act or omission which causes inconvenience or damage to a private person. There must be some sensible diminution of these rights affecting the value or convenience of the property. "The real question in all the cases is the question of fact, whether the annoyance is such as materially to interfere with the ordinary comfort of human existence" (Lord Romilly in *Crump v. Lambert*, 1867, L.R. 3 Eq. 409). A private nuisance, differing in this respect from a public nuisance; may be legalized by uninterrupted use for 20 years. (*See ANNOY.*)

The remedy for a public nuisance is by information, indictment, summary procedure or abatement. An information lies in cases of great public importance, such as the obstruction of a navigable river by piers. In some matters the law allows the party to take the remedy into his own hands and to "abate" the nuisance. Thus, if a gate be placed across a highway, any person lawfully using the highway may remove the obstruction, provided that no breach of the peace is caused thereby. The remedy for a private nuisance is by injunction, action for damages or abatement. An action lies in every case for a private nuisance; it also lies where the nuisance is public, provided that the plaintiff can prove that he has sustained some special injury. In such a case the civil is in addition to the criminal remedy.

In Scotland there is no practical distinction between public and private nuisances, the remedy against either being interdict or damages. The law as to what constitutes a nuisance is substantially the same as in England. There is a list of statutory nuisances in the Public Health (Scotland) Act 1867, and amending acts.

The American law on the subject is practically the same as the English law.

NUKHA, a town of Russia in the Azerbaijan S.S.R. in 41° 11' N., 47° 8' E., on a winding road linking Baku with Tiflis, and on the Nakhichevan river. Pop. (1926) 22,965. It is occupied in the breeding of silkworms and has five silk spinning factories. Hajji Chelyabi, the founder of the khanate of Sheki, chose the town as his residence in the 18th century and it remained the capital of the khanate until 1819, when it finally became Russian.

NULLIFICATION, the process of making null or of no effect (Lat. *nullus*, none). In United States history the term is applied to the process by which a state either (a) in fact suspended, or (b) claimed a constitutional right of suspending, the operation of a federal law within its own territory. The doctrine of nullification as a constitutional theory was probably never held by a majority of the states or of the American people at any one time, though before 1860 most of the states asserted or practised it. The belief in nullification was based on the theory that the union of the states was a voluntary one, each member retaining its sovereignty, though for purposes of convenience delegating certain powers of government to an agent—the federal government. The powers of this agent were strictly limited by the Constitution, and should it transcend these powers the states must interpose to protect their rights. This view held that the Supreme Court created by the Constitution was not a proper tribunal to decide causes arising beyond the Constitution or relating to the nature of the Union, but that its jurisdiction was limited to cases arising under the Constitution. If the Federal Government usurped a right belonging to the state, the latter, being a sovereignty, must judge for itself.

As later perfected by John C. Calhoun (*q.v.*), the theory of nullification required a practice as follows. A state aggrieved

by a law of the Federal congress might, in constituent convention, suspend the operation of the objectionable law, and report its action to the other states. If three-fourths of them should decide that the law in question was not unconstitutional, then in effect it became ratified (*see* United States Constitution, art. v.). The dissatisfied state must then submit or draw out of the Union by secession (*see* SECESSION, and CONFEDERATE STATES).

The earliest assertions of the doctrine of nullification are found in the Kentucky and Virginia resolutions of 1798–99, written respectively by Thomas Jefferson and James Madison in protest against the Alien and Sedition Acts of Congress. Nullification was first practised in 1809 by Pennsylvania, the governor ordering out the state troops to resist the execution of a decree of a Federal court. In the New England states, 1809–15, the United States laws relating to embargo, non-intercourse and army enlistments were nullified by state action. From 1825–29 the state of Georgia forcibly prevented the execution of Federal laws and court decrees relating to the Indians within her borders and in Alabama, 1832–35, there was a similar nullification. The only example of nullification in which theory and practice coincided was the nullification in 1832 by South Carolina of the Federal tariff laws. In this the state acted upon the theory outlined above which was perfected by Calhoun. In the last decade before the Civil War 14 of the Northern states in the so-called "Personal Liberty laws" nullified the Federal statutes relating to slaves and slavery by making it a crime for their citizens to obey these laws. Since the Reconstruction the Southern states have in practice effected a nullification of the Fourteenth and Fifteenth amendments to the Constitution providing for negro suffrage.

(W. L. F.)

NULLITY OF MARRIAGE, a judicial declaration that a marriage was null and void *ab initio* (from the beginning). In the 12th century the Roman law doctrine of nullity of marriage was developed in order to deal with hard cases under the principle of the indissolubility of marriage laid down by the Church of Rome, whose canons at that date governed the matrimonial law for the whole of Christendom. Nullity could be sued for on the grounds of affinity, into which the law of adoption entered very largely, or a previous unconsummated marriage, which latter was a ground for nullity in England as late as 1750. There were, and continue to be in Roman Catholic countries, various other grounds for nullity, but the grounds of nullity in England are at present limited to the following: (1) Where the parties are not by reason of age (14 for a male and 12 for a female), mental capacity, or otherwise capable of contracting marriage; (2) where the parties are within the prohibited degrees of affinity or relationship; (3) where one of the parties is already married; (4) where one of the parties does not freely consent to marry the other or does not understand the nature of the contract or ceremony; (5) where certain forms have not been observed; (6) where the form of marriage is essentially polygamous. Forms of marriage which offend against these rules are void *ab initio*. If at the time of the marriage one of the parties is and continues to be incapable of consummating the marriage by reason of some incurable physical defect, or of some incurable mental disability on the part of the man preventing him from consummating the marriage, or on the part of the woman resulting in her refusal of marital rights, the marriage may be annulled on the petition of the other party. A person may claim as a ground of nullity that he or she was insane at the time of the marriage. For the prohibited degrees of affinity *see* MARRIAGE.

The Royal Commission on Divorce which reported in 1913

recommended the following additional grounds of nullity of marriage: (1) When the other party, though of sufficient understanding to consent to a marriage, is at the time of the marriage either of unsound mind in other respects, or in a state of incipient mental unsoundness which becomes definite within six months after marriage, and the first party is at the time of the marriage ignorant of the defect, provided that (a) the suit is instituted within a year of the celebration of the marriage; (b) there has been no marital intercourse after discovery of the defect; (2) where the other party at the time of the marriage is subject to epilepsy or to recurrent insanity, and such fact is concealed by such party or his or her parents or either of them, or by anyone who has control over such party and is aware of the intended marriage, and the first party remains ignorant of the fact at the time of the marriage, subject to the same limitations for petitioning as in (1) above; (3) where one of the parties at the time of the marriage is suffering from a venereal disease in a communicable form, and the fact is not disclosed to the other party; (4) where a woman is pregnant by some other man at the time of the marriage and the husband is ignorant of the fact; (5) where there has been wilful refusal, without reasonable cause to allow intercourse, and where in fact there has been no intercourse owing to such refusal. (See also *DIVORCE*.)

See W. Rayden, *Practice and Law in the Divorce Division* (2nd. ed., by C. Mortimer, 1926); Sir L. Dibdin, *Reformatio Legum Ecclesiasticarum*, vol. iii. (1912); Report of the Royal Commission on Divorce and Matrimonial Causes (1913). (W. L. A.)

United States.—Three different situations relating to the nullity of marriage must be distinguished. A marriage may in the first place be totally void. No suit is necessary for its annulment and third parties can set up the fact of its invalidity. This, for example, is generally true of a bigamous marriage. Secondly, a marriage may be voidable at the election of one of the parties. No judicial decree is in theory necessary, though it is customary to secure a judicial declaration of nullity. Non-age of a party generally permits him thus to avoid the marriage, rendering it invalid *ab initio*, but until avoided by the act of the party it is valid, and third parties have no rights to contest its validity. Thirdly, as in the cases of marriage within the prohibited degrees of affinity, a suit to annul the marriage may be essential and such suit must be brought within the lifetime of one of the parties. The decree of annulment also relates back to the time of the marriage. The chief tendencies manifested by the many statutes in this field, apart from specifying the grounds for annulment, relate to: preserving the legitimacy of children born prior to the decree of annulment; making all annulments dependent upon judicial action and, in some instances, permitting the court in its discretion to deny or withhold relief; limiting the right to sue for annulment to a short space of time after discovery of the cause for annulment; permitting courts to award alimony upon decreeing annulment; allowing the injured party to a subsisting marriage to bring suit for its annulment; permitting courts in their discretion to hold trials for annulment in camera.

The grounds for annulment commonly recognized are: bigamy, impotency, non-age, marriage within the prohibited degrees of affinity, non-compliance with an essential statutory formality, mental incapacity existing at the time of the marriage. Among grounds that are recognized in some States by legislation, though not generally recognized, are: fraud, duress or mistake in the granting of consent to marriage, wilful refusal of a party to consummate the marriage by sexual intercourse, venereal disease or other serious illness existing at the time of the marriage and unknown to the other party, pregnancy due to some third party at the time of marriage and unknown to the other party. The causes for annulment are now generally specified by statute and these vary from State to State. Wide legislative activity in this field is due to the fact that in the United States no courts succeeded to the jurisdiction of the English ecclesiastical courts. Consequently no action for annulment on grounds entertained by the English ecclesiastical courts could be maintained in the absence of statute though equity courts would entertain such actions on grounds other than the canonical disabilities. Under such a theory

the intervention of the legislature became necessary and in short time legislation expanded to bring the entire field within its control. (J. M. L. A.)

NUMANTIA, an ancient hill fortress in northern Spain, in the province of Soria (Old Castile), overhanging the village of Garray, near the town of Soria, on the upper Douro. Here, on a small isolated high plateau in the middle of the valley, was the stronghold which played the principal part in a famous struggle between the conquering Romans and the native Spaniards during the years 154–133 B.C. Numantia was especially concerned in the latter part of this war from 144 onwards. It was several times unsuccessfully besieged. Once the Roman general Hostilius Mancinus with his whole army was compelled to surrender (137). Finally, Scipio Aemilianus, Rome's first and only general in that age, with some 60,000 men drew round the town 6 m. of continuous entrenchments with seven camps at intervals. After 15 months (134–133) he reduced by hunger the 6,000–8,000 Numantine soldiers, much as Caesar afterwards reduced Alesia in Gaul. The result was regarded as a glorious victory, and in Roman literature the fall of Numantia was placed beside the fall of Carthage. The site was, under the Roman Empire, occupied by a Roman town called Numantia, and the *Itinerary* tells of a Roman road which ran past it. It is to-day a "Monumento Nacional" of Spain, and has yielded remarkable discoveries to the skilful excavations of Dr. Schulten (1905–1910), who has traced the Celtiberian town, the lines of Scipio and several other Roman camps dating from the Numantine Wars. (F. J. H.)

NUMA POMPILIUS, second legendary king of Rome (715–672 B.C.), was a Sabine, a native of Cures, and his wife was the daughter of Titus Tatius, the Sabine colleague of Romulus. He was elected by the Roman people at the close of a year's interregnum, during which the sovereignty had been exercised by the members of the senate in rotation. Nearly all the early religious institutions of Rome were attributed to him. He set up the worship of Terminus (the god of landmarks), appointed the festival of Fides (Faith), built the temple of Janus, reorganized the calendar and fixed days of business and holiday. He instituted the flamens (sacred priests) of Jupiter, Mars and Quirinus; the virgins of Vesta, to keep the sacred fire burning on the hearth of the city; the Salii, to guard the shield that fell from heaven; the pontifices and augurs, to arrange the rites and interpret the will of the gods; he also divided the handicraftsmen into nine guilds. He derived his inspiration from his wife, the nymph Egeria, whom he used to meet by night in her sacred grove. After a long and peaceful reign, during which the gates of Janus were closed, Numa died and was succeeded by the warlike Tullus Hostilius. Livy (xl. 29) tells a curious story of two stone chests, bearing inscriptions in Greek and Latin, which were found at the foot of the Janiculum (181 B.C.), one purporting to contain the body of Numa and the other his books. The first when opened was found to be empty, but the second contained fourteen books relating to philosophy and pontifical law, which were publicly burned as tending to undermine the established religion.

No single legislator can really be considered responsible for all the institutions ascribed to Numa; they are essentially Italian, and older than Rome itself. Even Roman tradition itself wavers; e.g., the *fetiales* are variously attributed to Tullus Hostilius and Ancus Marcius. The supposed law-books, which were to all appearance new when discovered, were clearly forgeries.

See Livy i. 18–21; Plutarch, *Numa*; Dion. Halic. ii. 58–76; Cicero, *De republica*, ii. 13–15. For criticism: Schwegler, *Römische Geschichte*, bk. xi.; Sir G. Cornwall Lewis, *Credibility of early Roman History*, ch. xi.; W. Ihne, *Hist. of Rome*, i.; E. Pais, *Storia di Roma*, i. (1898), where Numa is identified with Titus Tatius and made out to be a river god; J. B. Carter, *The Religion of Numa* (1906); O. Gilbert, *Geschichte und Topographie der Stadt Rom im Altertum* (1883–1885); and *ROME: Ancient History*.

NUMBER, an abstract term for the integers 1, 2, 3, . . . as well as for the various mathematical generalizations of the integers, such as fractions and irrational quantities. It is also used as a concrete term. The practice of specifying the multiplicity of classes of objects by means of marks (integers) is found at an early stage in all civilizations, and has led to various systems of

numeration (see NUMERALS and ARITHMETIC). The ordinary decimal system is now in general use. While the particular system of numeration to be adopted is a matter of no theoretic importance, nevertheless, to insure the free development of the concept of number, some symbol for zero must be introduced, as well as symbols for addition, subtraction, multiplication and division. Over two thousand years ago the Greek philosopher Pythagoras (*q.v.*) foresaw the fundamental rôle of number and gave it a central place in his philosophy. The actual progress made however in the development of the concept of number is not to be found in the many philosophical speculations on the subject, but rather in the technical researches of mathematicians. In what follows our purpose will be to outline the essential ideas involved in this development.

INTEGERS

The simplest and most fundamental type of number is that of the integers. This type may be analyzed in the following manner. Consider two classes of objects A and B , each of which has only a finite number of constituent elements. Suppose that the elements of A and of B can be put in "one-to-one correspondence." In other words suppose that the elements of A can be paired with the elements of B just as the fingers of one hand can be paired with those of the other. Suppose, furthermore, that the elements of A and of a third class C can be put in one-to-one correspondence in the same way. It is then evident that the elements of B and of C can also be put in one-to-one correspondence. Thus the various classes B , C , . . . in one-to-one correspondence with A are also in one-to-one correspondence with one another.

An integer may be defined as a mark associated with such a collection of classes A , B , C . . . ; e.g., the integer 5 is the mark associated with the class of fingers on a hand and with all other classes in one-to-one correspondence with this particular class. It is reasonable to believe that even before the dawn of primitive civilization the first step in the use of the integer must have been taken in some such way as the following. A herdsman might set one stone aside for each animal in the herd. By use of the pile of stones he would be able to determine at any time whether or not his herd was complete. Later a series of scratches might serve as a simplified mark, and it is easy to see how the long continued use of such methods would lead to complete systems of numeration.

In basing the notion of the integer upon that of one-to-one correspondence, the classes were assumed to have only a finite number of constituent elements. Since the notion of a finite number of elements is thus involved at the outset, our analysis might seem to involve circular reasoning. This is not really the case since the notion of one-to-one correspondence of itself furnishes a method of distinguishing between finite and infinite classes. We may define an "infinite" class as one which can be put in one-to-one correspondence with a part of itself. For example, the class of integers 1, 2, 3, . . . will be infinite according to this definition since it may be put in one-to-one correspondence with the class of even integers 2, 4, 6, . . . ; we need only make an integer n of the first class correspond to its double $2n$ of the second class:

1, 2, 3, 4, . . .
2, 4, 6, 8, . . .

Likewise we may define a "finite" class as one which cannot be put in one-to-one correspondence with a part of itself.

Operations with the Integers.—If a and b are the integers for two classes A and B having no elements in common, and if these classes be combined to form a new class S , the integer s for S is determinable from the integers a and b . Indeed the underlying notion of correspondence shows that if A' and B' are any two other classes having no elements in common, whose integers are also a and b , then the integer for the combined class S' formed from A' and B' will be the same integer s as before. To make this fact clear, we need only observe that when A and B are put in one-to-one correspondence with A' and B' respectively, S is put coincidentally in one-to-one correspondence with S' . The integer s is called the "sum of a and b "; in the language of algebraic

symbolism we write $s=a+b$. The operation of determining s when a and b are given is called *addition*. Thus the operation of addition corresponds to the fundamental logical process of combination of two classes.

Similarly there may be a classes, each of which contains the same number b of elements, while no two of these classes have an element in common. If these classes be combined to form a new class composed of all these elements, its integer p is determinable from a and b , as follows in a similar manner. The integer p is called the "product of a and b "; $p=a \times b$, and the corresponding operation is called *multiplication*. Thus the operation of multiplication corresponds to the combination of a number of distinct classes, themselves in one-to-one correspondence with each other.

The two operations of addition and multiplication are usually considered to be the two fundamental operations. The inverse operations of subtraction and division may be defined by means of the respective equations

$$(a-b)+b=a, \quad \left(\frac{a}{b}\right) \times b=a.$$

Consequently the symbol $a-b$ will represent an integer if and only if b is smaller than a (i.e., some class B can be put in one-to-one correspondence with a part of some class A). Likewise a/b will represent an integer if and only if a contains b as a factor. The successive integers may be defined in terms of addition as follows:

$$1+1=2, 2+1=3, 3+1=4, \dots$$

Here 1 is to be regarded as the integer for any unit class. The definition of multiplication makes it clear that multiplication of any integer by 1 does not affect the integer.

The Five Fundamental Laws of Operation.—The notion of the integer, as based upon the one-to-one correspondence of classes, shows immediately that certain simple laws must hold. For instance since the class C , obtained by the combination of two classes A and B , is the same whichever class is mentioned first, we infer that the sum of two integers is independent of the order in which they are taken. This law has been termed the *commutative law of addition* (see COMMUTATIVE LAWS), and is the first of the five fundamental laws written below in algebraic form:

- (i) $a+b=b+a$,
- (ii) $(a+b)+c=a+(b+c)$,
- (iii) $a \times b=b \times a$,
- (iv) $(a \times b) \times c=a \times (b \times c)$,
- (v) $a \times (b+c)=(a \times b)+(a \times c)$.

The second *associative law of addition* (see ASSOCIATIVE LAWS) declares that if a third integer be added to the sum of a first and second integer, then the sum obtained is the same as if the sum of the second and third integers were added to the first; either process will give the sum of all three integers. In fact if the combination of two classes A and B is followed by a combination of the resulting class with a third class C , the combination of A , B , and C is obtained, just as when A is combined with the combination of B and C . Consequently the first two laws embody the principle that when integers are added, the final sum obtained is the same, no matter in what arrangement the operations of addition are performed.

The third and fourth laws embody an entirely analogous principle in connection with multiplication; viz., that when integers are multiplied, the final product obtained is the same, no matter in what arrangement the operations of multiplication are performed. However the reason for this principle is not quite so immediate. It may be formulated as follows: First consider two distinct classes A and B with a and b elements respectively. A class may be formed whose elements are all possible pairs of elements, one from A and the other from B . For each element of A there will be b elements of B which may be associated with it. Consequently by the definition of multiplication there will be $a \times b$ pairs in all, or equally $b \times a$ of course. Thus we obtain the

third *commutative law of multiplication*. The same justification may be presented in a simple graphical form. A rectangular array of $a \times b$ dots may be regarded either as a rows of b dots each or as b rows of a dots each.

Secondly, consider three distinct classes A , B and C with a , b , and c elements. A class may be formed whose elements are all possible triples of elements, one from A , one from B , and one from C . Evidently the class of triples so obtained may also be formed by taking the class of pairs from A and B mentioned above, and associating any such pair with any element of C to form a triple. Likewise the same class of triples may be constructed by taking the class of pairs from B and C and associating any such pair with any element of A . In this way the fourth *associative law of multiplication* is justified. This justification may also be given graphical form by use of an array of $a \times b \times c$ dots in space arranged in the form of a rectangular parallelepiped.

The fifth *distributive law of multiplication* (see DISTRIBUTIVE LAW) may be seen to hold as follows. The class of pairs of elements taken one from the class A and the other from the combination of B and C is evidently merely the combination of the class of pairs taken from A and from B , with the class of pairs taken from A and C . This, too, admits of graphical justification, since an array of $a \times (b+c)$ dots is evidently made up of an array of $a \times b$ dots and an array of $a \times c$ dots.

These five general laws contain all of the principles necessary for the manipulation of the integers, provided that we take for granted the special law, $a \times 1 = a$. In particular we can deduce the usual addition and multiplication tables for the integers by the aid of these laws; as an illustration we find

$$\begin{aligned} 2+2 &= 2+(1+1) = (2+1)+1 = 3+1 = 4, \\ 2 \times 2 &= 2 \times (1+1) = (2 \times 1) + (2 \times 1) = 2+2 = 4. \end{aligned}$$

THE REAL NUMBER SYSTEM

Positive or Ordinary Numbers.—The concept of quantity expressed in terms of a suitable unit of measure is of almost the same intuitive nature as the concept of the integer. This is particularly true of geometric quantities such as lengths, areas and volumes. In the case in which the given quantity contains the unit an exact number of times, it is clear that the quantity may be designated by means of the corresponding integer.

For similar reasons a fraction $\frac{m}{n}$ (m and n being integers) may be taken to represent the n th part of m units.

Fractions were employed as early as 1700 B.C. by the ancient Egyptians, but the concept of ordinary number was first adequately presented by Euclid. In the tenth book of his *Elements* he considered geometric magnitudes, and distinguished between commensurable and incommensurable quantities. For instance he established that the hypotenuse of an isosceles right triangle is incommensurable with the other two equal sides. In other words the number $\sqrt{2}$, representing the hypotenuse in terms of one of the equal sides taken as unit, is an *irrational* number, not expressible as a fraction $\frac{m}{n}$. How then shall such irrational num-

bers be represented by means of marks? This must be accomplished with the aid of a sequence of fractions which approach the irrational number as a *limit*. For instance when $\sqrt{2}$ is represented in the form of an infinite decimal: $\sqrt{2} = 1.4142 \dots$, this amounts to a specification of $\sqrt{2}$ by means of the sequence of fractions

$$1, \frac{14}{10}, \frac{141}{100}, \frac{1414}{1000}, \frac{14142}{10000}, \dots$$

The fundamental operation of addition of two such numbers may be interpreted geometrically, and in this way it is intuitively evident that the first two general laws must continue to hold.

Zero and Negative Numbers.—The real number system includes not only the positive or ordinary numbers, but zero and the so-called negative numbers, and is the system of most theoretical importance in the actual application of number to scientific questions. It might be shown how in various fields such

a further extension is very natural; for instance in dealing with temperature we must select an initial or zero point of the scale and must differentiate between temperatures above and below this point. Instead of doing so we propose to indicate how more purely mathematical considerations suggest this further extension. Similar considerations also suggest the extension already made from the integers to the fractions, but this extension can be based so directly upon experience as to make the statement of the purely mathematical considerations seem superfluous. The mathematical considerations entering are the following:

For the free manipulation of numbers the use of the inverse operations is an indispensable adjunct. We may deduce the general laws for such operations from the five fundamental laws. One illustration of this must suffice. The usual algebraic rule for the addition of two fractions with a common denominator is embodied in the formula

$$\frac{a}{d} + \frac{b}{d} = \frac{a+b}{d}.$$

To establish this law we may write $\frac{a}{d} = x$, $\frac{b}{d} = y$, whence we find $xd = a$, $yd = b$, in virtue of the definition of division. By addition we infer that

$$xd + yd = (x+y)d = a+b,$$

whence follows $x+y = \frac{a+b}{d}$, which it was desired to prove.

In this free manipulation of quantities with the aid of these inverse operations, such symbols arise as $1-1$, $1-2$, which do not represent ordinary numbers. Yet it is soon found that if formally correct manipulations are made regardless of the meaning of the symbols, the correct result is always obtained. This situation suggests inevitably that such symbols in reality represent a valid kind of number.

Let us assume that this is the case and consider the conclusions which follow. For brevity let us write $a-a=0$. This definition will be legitimate since we can establish formally that the equality

$$a-a=b-b$$

holds whatever a and b may be. The two further special laws $a \times 0 = 0$, $a+0 = a$ are obeyed by this symbol 0 , and are of the same nature as the special law $a \times 1 = a$ already mentioned.

Next write for the sake of brevity

$$0-a=-a$$

in case a is a positive number. Such a quantity may be called *negative*. With this extension of the number system to include 0 and the negative quantities, all symbols are found to be formally reducible to the same type, provided that division by 0 is excluded. Consequently the extension of the ordinary numbers by the introduction of zero and the negative numbers follows from the free formal use of the laws of operation. Furthermore the rules for dealing with such numbers are obtained in the same way; for example the conclusion that the product of $-a$ and $-b$ is ab follows in this way.

Up to this point the method of approach has been heuristic rather than logical. It is now a simple matter to explain the method by which the real numbers can be satisfactorily defined in terms of ordinary numbers. We propose to consider ordinary numbers, the number 0 , and ordinary numbers with a $-$ symbol prefixed. The first type of mark will be referred to as a positive number and the last type as a negative number. The number 0 will be regarded as a member of either type; i.e., $-0=0$ by convention. The rules of combination of these marks under the operations \oplus and \otimes (which are not to be confused with the operations $+$ and \times) will be defined in the following manner: If a and b are positive $a \oplus b$ is the positively taken sum; if either a or b is negative $a \oplus b$ is their difference considered as positive if the positive term is numerically greater, and negative in the contrary case; if both a and b are negative, $a \oplus b$ is their ordinary sum taken as negative. Likewise if a and b are both positive or both negative $a \otimes b$ is the positively taken product; and if one

is positive and the other negative, $a \otimes b$ is the negatively taken product. Finally we define $a \oplus o$ and $o \oplus a$ to be a in all cases, and $a \otimes o$ and $o \otimes a$ to be o in all cases.

It may then be verified, upon the basis of the properties of ordinary numbers, that the *extended real number system* satisfies the general and special laws of operation in all cases whatsoever; for example it may be verified that the commutative law of addition holds always. Furthermore it is readily verified that the inverse operations (except division by o) can be performed. These inverse operations will of course obey the usual formal laws which can be deduced from the five general laws for the direct operations. Hence we are fully justified in regarding the real number system so obtained as a complete generalization of the ordinary number system.

THE COMPLEX NUMBER SYSTEM

As soon as equations of the second and higher degree are considered, a further and (in some ways) final extension of the number system is suggested. In fact the general formula for the solution of an equation of the second degree involves the extraction of the square root of a quantity which may be negative. But no real quantity has a negative square. Hence we are again led to meaningless symbols. However the symbol for the solution can be reduced formally to $a + bi$ where i stands for $\sqrt{-1}$ so that $i^2 = -1$. Here bi is an abbreviation for $b \times i$.

The question then arises as to whether these symbols can be regarded as an appropriate generalization of the real numbers. If we write

$$(a + bi) + (c + di) = (a + b) + (c + d)i,$$

$$(a + bi) \times (c + di) = ac + (ad + bc)i + bd i^2 = (ac - bd) + (ad + bc)i,$$

we define thereby the operations of addition and multiplication of these complex or imaginary numbers. It may then be verified that the usual formal laws will be satisfied in all cases. Consequently the further extension of the number system must be regarded as legitimate.

The above treatment may be clarified as follows. Let us begin by defining a complex number as a pair of associated real numbers (a, b) . The definitions of addition \oplus and multiplication \otimes may be written

$$(a, b) \oplus (c, d) = (a + c, b + d)$$

$$(a, b) \otimes (c, d) = (ac - bd, ad + bc).$$

Furthermore as a means of abbreviation we may write $(a, o) = a$ and call these pairs a the real numbers of the extended system; in particular we have $(o, o) = o$, $(1, o) = 1$. Likewise we write $i = (o, 1)$, and find from the definition of multiplication

$$i^2 = i \otimes i = (-1, o) = -1.$$

We are now in a position to deduce

$$(a, b) = (a, o) \oplus (o, b) = (a, o) \oplus (b, o) \otimes i = a \oplus (b \otimes i),$$

which is essentially the form of expression $a + bi$ with which we started.

When this complex number system is adopted the solution of all algebraic equations of any degree may be accomplished, even when the coefficients are themselves complex numbers. Thus from an algebraic standpoint no further generalization is called for. The so-called Argand diagram represents complex numbers by means of the points of a plane, and makes it evident graphically that these numbers satisfy the general and special laws. (See COMPLEX NUMBERS.)

BASIS OF THE NUMBER SYSTEM

The Integers as Basis.—We are now in a position to indicate in what sense the integers alone may be regarded as basis for these extensions. Our first step is to define a fraction as a pair of associated integers $\frac{p}{q}$, and to define addition and multiplication of fractions by the usual algebraic formulae. It is then readily verified on the basis of the properties of the integers that such

fractions obey the five general laws. We regard two fractions $\frac{p}{q}$ and $\frac{p'}{q'}$ as "equal" if $p q' = q p'$. Furthermore we write $\frac{a}{1} = a$, and find that the first special law also holds. We may next introduce the inverse operations and obtain the usual corresponding laws from the five fundamental laws.

The System of Postulates.—In the course of the preceding development certain general and special laws were found to be characteristic of various types of number systems. It is of decided interest to investigate the question as to whether these laws are sufficient to characterize such systems. This can be accomplished by means of the postulational method. Here certain postulates are formulated in terms of certain elements and operations, and it is then proved that the elements and operations are essentially the numbers and the operations of addition and multiplication.

A natural set of postulates with which to begin is the following. The set of elements and $+$, \times obey the fundamental laws I–V; there are two special elements o , 1 which obey the special laws. The equations

$$a + x = b, a \times x = b$$

have a unique solution x for all values of a and b , except for $a = o$ in the second case.

These postulates however do not suffice. In fact they hold for the set of positive and negative fractions, for the real number system, and for the complex number system. They also hold for certain modular number systems referred to later in which there are only a finite number of elements; the simplest such system contains only three marks o , 1 , 2 with addition and multiplication defined by the following tables:

+	o	1	2
o	o	1	2
1	1	2	o
2	2	o	1

×	o	1	2
o	o	o	o
1	o	1	2
2	o	2	1

The complete treatment of the ordinary number system which Huntington has given introduces the further relation $<$ (less than).

The advantage of such a postulational analysis is that we are led to see what are the essentially independent properties of an assigned number system. By the modification or removal of one or more of the postulates other types of number are obtained; e.g., if to the above set we add the postulate that there are three distinct elements, it may be proved immediately that the modular system specified is obtained.

SYMBOLIC LOGIC AND THE INTEGER

Symbolic logic attempts to reduce the so-called logical processes of thought to explicit objective form in such wise that logical reasoning may be comparable in its mechanical precision and objective quality with a game such as chess. Here the paper on which the symbolic propositions are written corresponds to the chessboard, and the symbols correspond to the chessmen. There is given an initial set of "true" propositions which corresponds to the initial position of the chessmen with which we start.

Now this logical game and its rules, as ordinarily conceived, do not have any reference to number or even to the integers. It would of course be possible to insert at the outset a given set of true propositions (i.e., postulates) sufficient to characterize the set of integers. It would then be possible in accordance with the strictly prescribed logical processes to define the fractions. In developing the ordinary number system, it would be necessary to deal with an infinite ordered sequence of fractions.

Our method of approach to the ordinary integers was itself of a logical character, since it defined the integers in terms of the notion of one-to-one correspondence of classes, which is a purely logical one. Thus the fundamental and interesting question is suggested: in a symbolic logic not containing initial propositions which state the existence of the integers, might it not be possible to define the integers in purely logical terms? The kind of definition that has been considered by Frege, Russell and Whitehead

may be stated as follows in ordinary language: an integer is the class of all classes in one-to-one correspondence with some specified finite class. The one-to-one correspondence between two classes is a relation R between the elements of the classes which may be expressed in the form: for each element x of the first class there exists one and only one element y of the second class such that $x R y$; likewise for each y of the second class there exists one and only one x of the first class such that $x R y$.

The attempt to devise a satisfactory system of symbolic logic is beset with many difficulties. In particular it must be able to deal with certain paradoxes which have been encountered in the theory of infinite classes. A theory of types of proposition has been devised by Whitehead and Russell with this purpose in view. At the present time there is no general agreement among mathematicians as to the proper foundation of symbolic logic; but on the basis of the work of Whitehead and Russell it seems clear that if symbolic logic can be given a definite form, it will prove to be possible to define the positive integers in purely logical terms.

FURTHER GENERALIZATIONS

Modular and Hypercomplex Numbers.—There are many generalizations and modifications of number besides those referred to above. In particular there are the modular and Galois number fields in which there are only a finite number of marks (numbers) and in which all the usual formal laws are satisfied (see NUMBER, THEORY OF). There are also various hypercomplex number systems such as quaternions (see QUATERNIONS) in which there are more than the two "fundamental units" such as 1 and i of the ordinary complex number system. In these hypercomplex number systems, however, the commutative law of multiplication does not hold.

Transfinite Numbers.—The above-mentioned directions of generalization are technical in character. Of a much more fundamental nature is the extension of the notion of the integer as the mark of a finite class so as to apply to infinite classes. These *transfinite numbers*, discovered by G. Cantor, have attracted much interest and have led to certain paradoxes to which we cannot do more than allude. An infinite class has the property that it can be put into one-to-one correspondence with part of itself. This was illustrated above by means of the infinite sequence (see NUMBER SEQUENCES) of integers $1, 2, 3, \dots$; but from any infinite class we may remove such an infinite sequence.

Consider now a collection of classes which can be put in one-to-one correspondence with one another. These can be regarded as associated with a mark which is an ordinary integer if the classes contain a finite number of elements, and which is called a *transfinite cardinal*, if there are infinitely many elements in each class. The simplest such mark ω is that attached to the class of positive integers; ω is the mark characteristic of enumerable classes, i.e., of classes which may be put in one-to-one correspondence with the infinite sequence of integers $1, 2, 3, \dots$. The class of all fractions $\frac{m}{n}$ has also this transfinite cardinal ω , for these fractions may be ordered according to the size of the sum of numerator and denominator:

$$\frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{2}{3}, \frac{3}{2}, \dots$$

A first conjecture might be that all infinite classes have the transfinite cardinal ω . The following simple reasoning shows, however, that the class of all ordinary numbers between 0 and 1 has a greater transfinite cardinal than ω .

Suppose it possible that the class of these numbers has the transfinite cardinal ω . This would signify that all of these numbers could be written in a sequence S just as the integers $1, 2, 3, \dots$ can be written. First let us imagine the numbers of this sequence to be written in decimal form. Now certain rational numbers admit of double representation, as is evident from the fact that $0.879999 \dots = 0.880000 \dots$. Let us agree, in all such cases, to use the mode of representation by 9 's, so that every number shall have a unique decimal representation.

We may now construct another number less than 1 as follows: Let the first figure after the decimal point be chosen apart from 0 and the first figure of the first number of S ; the second figure be chosen apart from 0 and the second figure of the second number of S , and so on. There will then be defined a number in decimal form which is obviously distinct from all the numbers of S . Hence the hypothesis that the sequence contains all of the numbers between 0 and 1 is incorrect. The conclusion may be stated in the form: The continuum of numbers between 0 and 1 is not enumerable. By an extension of this method it is possible to define greater and greater transfinite numbers.

In the consideration of the transfinite cardinals various paradoxes arise unless some definite logical theory such as the theory of types of Russell and Whitehead is carefully adhered to. Moreover the precise structure of these transfinite numbers is not known except in the case of the least such number ω ; thus it is not known whether or not the transfinite cardinal of the continuum is the first exceeding ω or not.

Cardinal and Ordinal Numbers.—In the account of number given above no reference has been made to the usual elementary distinction between the cardinal and ordinal integers. Up to the time of the discovery of transfinite number this distinction possessed merely elementary pedagogical significance, and the mathematical treatment of number dealt exclusively with the cardinal integers. With the invention of the transfinite numbers, however, it appeared immediately that this distinction, although mathematically barren in the case of ordinary integers, lead to two distinct types of number when applied to infinite classes, namely to the transfinite cardinals and to the transfinite ordinals.

The distinction between cardinal and ordinal number may be expressed as follows in the case of finite classes. In the case of the cardinal type of integer we have a mark characteristic of the class without reference to any order of its elements; in the case of the ordinal type of integer the class is ordered and its elements are supposed to be counted in this order, the mark 1 being attached to the first element, the mark 2 to the second, and so on, to the end of the sequence. This gives an ordinal number for each element. Of course if the last element has the mark n , the cardinal number of the class is also n . Thus the two kinds of integer are very intimately related.

When we deal with infinite classes and attempt to extend the notion of ordinal number, it is necessary first of all to define what is meant by an ordered infinite class. First we have an infinite sequence $1, 2, 3, \dots$ as before. To continue with the ordinal numeration we call the next mark ω ; after it the successive marks are denoted by $\omega+1, \omega+2, \dots$, although this is merely by convention. Immediately after this sequence appears the next ordinal, denoted by $\omega \cdot 2$, followed by $\omega \cdot 2+1, \omega \cdot 2+2, \dots$, then $\omega \cdot 3, \omega \cdot 3+1, \dots$. Evidently this process of ordinal numeration is now part of a more extensive sequential process which may be written symbolically

$$\begin{aligned} &1, 2, \dots \\ &\omega, \omega+1, \omega+2, \dots \\ &\omega \cdot 2, \omega \cdot 2+1, \omega \cdot 2+2, \dots \\ &\dots \\ &\omega^2, \omega^2+1, \omega^2+2, \dots \\ &\omega^2+\omega, \omega^2+\omega+1, \omega^2+\omega+2, \dots \end{aligned}$$

Thus a series of order types of increasing complexity is formed, and the process may be continued indefinitely. These give the sequence of transfinite ordinals, appropriate to the numeration of well-ordered infinite classes. A class is said to be "well-ordered" if the elements are not only ordered but are such that every element or ordered sequence of elements has an immediately following element.

The marks for the transfinite ordinals are not the same as for the cardinals. Thus it is immediately evident that the set of transfinite ordinals up to ω^2 are enumerable; i.e., they have the transfinite cardinal ω . It is not as yet known whether or not every class, e.g., the continuum of numbers between 0 and 1 , can be well-ordered or not.

The theory of the transfinite cardinal and ordinal numbers, and their interrelations is of great philosophical as well as mathematical interest. The subject requires much further development. In particular the underlying basis of symbolic logic has not been agreed upon.

NUMBERS is the fourth book of the Pentateuch, as the five books of the Law, or of Moses, have come to be called. The three previous books carried on the story of Israel's history from the creation, through the captivity in Egypt and the escape therefrom, down to the sojourn at Sinai. Numbers traces out the march from Sinai, the wanderings in the wilderness and the final arrival on the steppes of Moab within sight of the Promised Land. Like the other books of the Pentateuch, it consists of earlier (JE) and later (P) sources; see **BIBLE: Old Testament**. But, although the sources come from different ages and from writers of different schools of thought, yet if its significance is properly to be apprehended, it is necessary to remember that for more than 2,000 years it has been a complete whole.

The book falls naturally into three sections which follow a chronological sequence; (1) Chaps. i.-x. 10 (P) Israel's sojourn at Sinai, the census and the promulgation of various laws by Moses. (2) Chaps. x. 11-xxii. 1 (JE and P), incidents which occurred during the wanderings between Sinai and the arrival at the steppes of Moab. These incidents seem to have been chosen mainly for the purpose of casting light on the religious history and character of the people and also to explain the meaning of various place-names (*cf.* Taberah and Kibroth hattaavah, xi. 3, 34). They also attempt to give an account of the origin of some religious objects of worship (*e.g.*, the brazen serpent, xxi. 4-11). (3) Chaps. xxii. 2-xxxvi. (mainly P) the sojourn on the steppes of Moab, the incident of Balaam, the second census and the giving of additional laws, together with various other incidents.

The middle section contains important passages from J and E: the twelve spies, the rebellion of Korah, and Balaam's mission to Balak (no signs of P). J, E, and P can be readily separated in chaps. xi. and xii. To E belongs the passage describing the outpouring of the Spirit on Eldad and Medad and the remarkable prayer of Moses in xi. 29, "Would God that all Yahweh's people were prophets that Yahweh would put his Spirit upon them." *cf.* the idea that Christians are "priests unto God" (Rev. i. 6). As usual the J and E elements possess such a vivid character as to render them familiar to ordinary readers; contrast P's legislative and statistical style, and his diffuseness (which reaches a climax in ch. vii.). The most illuminating example of the difference between JE and P is found in the passage that occurs after the first long section of P describing the order of march of the several tribes and the position of the ark in the very centre of the host, both when encamped and on the march. In x. 30 Moses entreats Hobab, the son of Reuel his father-in-law, to come with the Israelites to be "eyes" unto them; and in x. 33 it is stated that the ark went *before* them to seek out a resting-place for them. It is clear that these statements directly contradict P's elaborate scheme, according to which the people march mechanically, tribe by tribe, with the ark in the very centre of the square, and guided by the pillar of cloud by day and the pillar of fire by night. Moses, instead of simply following the pillar of cloud, requests Hobab to determine the line of march and select the sites for encampment. No clearer proof could be desired of the nature of early methods of compilation than that the detailed account in ch. i.-x. 28 should be immediately followed by two short paragraphs in palpable contradiction of the whole plan of camp and march so elaborately worked out in the preceding narrative.

Of very great interest is the account of Korah's revolt in ch.

xvi. which is composed of J, E, and P in a most intricate manner. Literary analysis has unravelled three stages of development: (a) two *Reubenites*, Dothan and Abiram, rebel against the *civil* authority of Moses; (b) Korah the Levite, with 250 *Israelites*, rebels against the *religious* authority of Moses and Aaron, and (c) Korah at the head of 250 *Levites* protests against the priestly privileges of Aaron (for details see the commentaries). The analysis (which is generally accepted) is of extreme value for the difficult study of the history of the Levites (*q.v.*).

Another very important narrative is that of Balaam (*q.v.*). It includes a number of poetical quotations which help to determine its date and also indicate the value of poetry in its bearing on history. Also in xxi. 14 we have a poetical quotation from a lost volume of early poetry entitled "The Book of the Wars of Yahweh." Deborah's song was probably originally in this book; and when we compare its statement as to Israel's full fighting strength, viz., 40,000 men, with the statements in the prose of Numbers as to 600,000 men and more, we at once realize how much closer to actual facts we are brought by early poetry than by the later prose of writers like P. Perhaps it is in chap. xxxii. that we have the clearest proof of P's non-historical character. There we are told that 12,000 Israelites, without losing a single man, slew every male Midianite, children included, and every Midianite woman that had known a man, and took so much booty that there had to be special legislation as to how it should be divided. But if this were actual fact, how could the Midianites have ever reappeared in history? And yet in Gideon's time they were strong enough to oppress Israel.

See Commentaries of G. B. Gray, *Internat. Crit. Com.*, L. E. Binns *Westm. Comm.*, McNeile *Cumb. Bible*, A. R. S. Kennedy *Century Bible*. (J. A. P.; L. E. B.)

NUMBERS, THEORY OF. The theory of numbers deals primarily with positive and negative whole numbers, called integers. For example, to take the simplest kind of proposition, if n is any integer, $n(n+1)$ is divisible by 2, $n(n+1)(n+2)$ is divisible by 3, etc. Many apparently very simple theorems concerning integers require for their actual proof various branches of mathematics. Frequently a proof employs the theory of algebraic numbers (such as $2+\sqrt{3}$), which is one of the advanced parts of the theory of numbers.

MAIN PROPERTIES OF DIVISIBILITY

Theorems of Fermat and Euler. Primitive Roots.—A positive integer, like 7, is called a *prime* if it has no factor except itself and 1. But $6=2\times 3$ is composite. Two integers, like 8 and -15 , are called *relatively prime* if they have no common factor >1 .

In 1640 Fermat stated that, if p is any prime and if n is any integer not divisible by p , then $n^{p-1}-1$ is divisible by p . For example, $3^4-1=80$ is divisible by 5. The generalization by Euler in 1760 states that if m is any positive integer, prime or composite, and if n is relatively prime to m , then $n^{\phi(m)}-1$ is divisible by m . Here $\phi(m)$ denotes the number of positive integers not exceeding m which are relatively prime to m . For example, these are 1, 5, 7, and 11 when $m=12$, so that $\phi(12)=4$, and $5^4-1=624$ is divisible by 12.

Euler's theorem shows that the linear equation $nx\pm my=c$, in which n and m are relatively prime, has the integral solution $x=cn^k$, $y=\mp cq$, where $k=\phi(m)-1$ and q is the quotient of $n^{\phi(m)}-1$ by m .

A *primitive root* n of m is such that $\phi(m)$ is the least positive exponent e for which n^e-1 is divisible by m . For example, 2 is a primitive root of 5, since 2^4-1 is divisible by 5, while no one of $2-1$, 2^2-1 , 2^3-1 is divisible by 5. Again, 5 and 7 are primitive roots of 6. There exist primitive roots of m if and only if m is 2, 4, p^k , or $2p^k$, where p is an odd prime.

Quadratic Residues. Law of Reciprocity.—When the squares 1^2 , 2^2 , 3^2 are divided by 7, the positive remainders <7 are 1, 4, 2, which are called *least quadratic residues* of 7. Evidently the squares of $4=7-3$, $5=7-2$, $6=7-1$ have the same remainders as the squares of 3, 2, 1. Likewise, 8^2 , 9^2 , \dots have the same remainders as 1^2 , 2^2 , \dots . Finally, the square of a multiple of 7 has the remainder zero, which is not counted as a

quadratic residue. Hence when all squares relatively prime to 7 are divided by 7, the only remainders < 7 are 1, 2, 4, which are therefore the only least quadratic residues of 7. The remaining positive integers 3, 5, 6 less than 7 are called the *least quadratic non-residues* of 7. Then if l is any integer, $3+7l$, $5+7l$, and $6+7l$ are called non-residues of 7; while $1+7l$, $2+7l$, and $4+7l$ are called residues of 7. Clearly the product of any two residues or of two non-residues is a residue, while the product of a residue by a non-residue is a non-residue.

The generalization from 7 to any m is immediate. If an integer r is relatively prime to m and if r differs from some square by a multiple of m , then r is a quadratic residue of m . But if n is relatively prime to m and if there is no integer x such that $x^2 - n$ is divisible by m , then n is a quadratic non-residue of m . If $m = 15$, we need only test the squares of 1, 2, 4, 7; their remainders 1 and 4 are the only least quadratic residues of 15. The remaining positive integers < 15 and relatively prime to 15 are 2, 7, 8, 11, 13, 14 and give all the least non-residues of 15.

If p is a prime > 2 , and if s is any integer not divisible by p , Legendre's symbol (s/p) is defined to have one of just two values, viz., $+1$ when s is a quadratic residue of p , and -1 when s is a non-residue. The earlier results give $(2/7) = +1$, $(3/7) = -1$. By use of the formulas

$$(s/p)(l/p) = (sl/p), \quad (-1/p) = (-1)^{(p-1)/2}, \quad (2/p) = (-1)^{(p^2-1)/8},$$

the computation of any symbol (s/p) is evidently reduced to that of (l/p) where l is an odd prime $\neq p$. In case $l > p$, we have $l = ap + r$, where $0 < r < p$. Since l and r are either both quadratic residues or both non-residues of p , $(l/p) = (r/p)$. Hence the computation always reduces to that of (q/p) , where q and p are distinct odd primes and $q < p$. We now make use of the reciprocity law:

$$(q/p)(p/q) = (-1)^e, \quad e = \frac{p-1}{2} \cdot \frac{q-1}{2}.$$

Hence (q/p) will be known as soon as (p/q) has been found. Since $p > q$, our former method applies to (p/q) . All these principles are illustrated in the following example:

$$\begin{aligned} (-22/73) &= (-1/73)(2/73)(11/73), \quad (-1/73) = +1, \quad (2/73) = +1, \\ (11/73) &= (73/11) = (7/11) = -(11/7) = -(4/7) = -1. \end{aligned}$$

Here it was necessary to know that 73, 11, and 7 are all primes. The removal of the restriction to primes would obviously save much work. Partly for this reason, but mainly on account of its importance in many investigations, we shall discuss *Jacobi's symbol*.

Let P be a positive odd integer. If $P = 1$, we take

$$(s/P) = (s/1) = +1.$$

But if $P = p_1 p_2 \cdots p_r$, where p_1, p_2, \cdots are odd primes, not necessarily distinct, we define Jacobi's symbol to be

$$(s/P) = (s/p_1)(s/p_2) \cdots (s/p_r).$$

In case an even number of these factors is -1 , the symbol (s/P) is $+1$ and yet s is a non-residue of P . While therefore Jacobi's symbol does not admit of the same interpretation as Legendre's, yet all the above formulas hold true, including the reciprocity law, provided p and q are now any relatively prime positive odd integers. If for $n = -P$ we define (s/n) to be (s/P) , we see that the reciprocity law holds also when just one of p and q is negative.

CLASSES OF FUNCTIONS. REPRESENTATION OF INTEGERS BY FUNCTIONS

Equivalent Functions and Equations.—The problem to find all solutions of $x^2 + y^2 = 41$ in integers is equivalent to that for $X^2 + 4XY + 5Y^2 = 41$, which is derived from the first equation by the substitution $x = X + 2Y$, $y = Y$. The discussion is not more difficult if we start with any substitution

$$x = aX + bY, \quad y = cX + dY, \quad (1)$$

in which the coefficients a, b, c, d are integers whose determinant

(see DETERMINANT) $ad - bc$ is ± 1 . Solving equations (1) for X and Y , we get

$$X = dx - by, \quad Y = -cx + ay.$$

Hence to any pair of integers x and y corresponds a single pair of integers X and Y , and conversely by (1). Let the substitution (1) replace the function $f(x, y)$ by $F(X, Y)$. Then if g is any given integer, the integral solutions of $f = g$ are put into one-to-one correspondence with those of $F = g$ by the substitution (1), so that the problem to find all solutions of $f = g$ in integers is evidently equivalent to that for $F = g$. We therefore need only treat one of the infinitely many equivalent equations.

These two functions f and F are called *equivalent*. Let $F(X, Y)$ become $G(u, v)$ when we apply the new substitution

$$X = qu + rv, \quad Y = su + tv, \quad (2)$$

with integral coefficients whose determinant $qt - rs$ is ± 1 . If we eliminate X and Y between the four equations (1) and (2), we evidently obtain equations of the form

$$x = Au + Bv, \quad y = Cu + Dv. \quad (3)$$

The coefficients are seen to be integers whose determinant is unity. This substitution (3) is called the product of the substitutions (1) and (2) taken in that order. Since (1) replaces f by F , and (2) replaces F by G , evidently (3) replaces f by G . This proves that if f and G are both equivalent to F , they are equivalent to each other. Hence all the functions which are equivalent to a given one f form a class of functions any two of which are equivalent. It is easy to extend this discussion for two variables x and y to any number of variables.

When $f(x, y, \cdots) = g$ has integral solutions, g is said to be represented by f . In case x, y, \cdots have no common factor > 1 , g is properly represented by f . For example, $2^2 + 3^2 + 4^2 = 29$, whence 29 is properly represented by $x^2 + y^2 + z^2$.

Positive Binary Quadratic Forms.—The function

$$f = ax^2 + bxy + cy^2$$

is called a binary quadratic form and is denoted by (a, b, c) . Its discriminant is $b^2 - 4ac$. Two equivalent forms have the same discriminant.

Let A be properly represented by f , whence $f = A$ for relatively prime integers $x = r$, $y = s$. As shown above, there exist two integers t and u such that $rt - su = 1$. The substitution

$$x = rX + uY, \quad y = sX + tY,$$

whose determinant is unity, replaces f by an equivalent form in which the coefficient of X^2 is A .

Let $a > 0$ and let the discriminant of f be a negative number $-\Delta$. Then

$$4af = (2ax + by)^2 + \Delta y^2$$

shows that f is positive for all real numbers x and y not both zero. Hence f is called a *positive form* (see ALGEBRAIC FORMS). Let A be the least positive integer which is represented by this f . If $f = A$ when $x = r$, $y = s$, and if r and s have a common factor $d > 1$, then $f = A/d^2$ when $x = r/d$, $y = s/d$, which contradicts the definition of A as least. Thus A is properly represented by f . As shown above, f is equivalent to some form $g = (A, \beta, \gamma)$ with A as first coefficient. The substitution $x = X + nY$, $y = Y$ replaces g by $F = (A, B, C)$, where $B = \beta + 2nA$. Evidently the integer n may be chosen so that $-A < B \leq A$. Since C is represented by F , C is not less than the minimum A . In case $C = A$, the substitution $x = -Y$, $y = X$, whose determinant is unity, replaces F by $(A, -B, A)$. This proves that every positive form is equivalent to a reduced form (A, B, C) in which

$$A < B \leq A, \quad C \geq A, \quad \text{with } B \geq 0 \text{ if } C = A. \quad (4)$$

Then $4A^2 \leq 4AC = \Delta + B^2 \leq \Delta + A^2$, $3A^2 \leq \Delta$.

Hence if Δ is given, there is a limited number of positive integral values of A . The same is now true for B by (4). Each pair of integers A and B determines at most one integer C for which $4AC = \Delta + B^2$. Hence there is only a finite number of positive

reduced forms having a given discriminant.

Example 1. To find the reduced forms whose discriminant is -4 . Since $3A^2 \leq 4$, the positive integer A is 1. By (4), $B=0$ or 1. Then $4C=4+B^2$ gives $B=0$, $C=1$. Hence x^2+y^2 is the single reduced form.

Example 2. Let the discriminant be -12 . Then $A=1$ or 2. If $A=1$, we get $F=x^2+3y^2$ as in Ex. 1. If $A=2$, $8C=12+B^2$ shows that B is even and $\neq 0$. Then (4) gives $B=2$. The resulting reduced form $(2, 2, 2)$ represents only even integers and hence is not equivalent to F .

The last example illustrates the theorem that no two reduced forms having the same negative discriminant are equivalent. This implies that the number of classes of positive binary quadratic forms having a given negative discriminant is exactly the number of reduced forms.

The importance of these ideas will become clear by considering the theorem that every prime p of the form $4n+1$ is sum of two squares. This fact was recognized by Girard in 1625. Euler was the first to publish proofs (1749, 1773, 1783). In 1854 Hermite gave the following immediate proof: Since $(-1/p) = +1$, -1 is a quadratic residue of p . In other words, there exist integers t and q such that $t^2+1=pq$. Hence the discriminant of

$$f = pX^2 + 2tXY + qY^2$$

is -4 . By Example 1, f is equivalent to the single reduced form x^2+y^2 of discriminant -4 . This means that there is a substitution (1) which replaces x^2+y^2 by f . Equating the coefficients of X^2 , we get $p=a^2+c^2$.

Euler noted that if we multiply $(a \pm bi)(c \pm di)$ by its conjugate imaginary, we obtain the identity

$$(a^2+b^2)(c^2+d^2) = (ac \mp bd)^2 + (ad \pm bc)^2 \quad (5)$$

known by Diophantus (*c.* 275; see DIOPHANTINE EQUATIONS). It now follows that an integer is a sum of two squares if and only if its quotient by the largest square dividing it is a product of primes all of the form $4n+1$, or the double of such a product.

If $p=a^2+b^2$ and $q=c^2+d^2$ are distinct primes of the form $4n+1$, the two numbers whose squares appear in the second member of (5) cannot have a common factor $f > 1$, since f^2 does not divide the first member pq . For all combinations of signs, $(\pm a, \pm b)$ and $(\pm c, \pm d)$ give the 8 representations of p by x^2+y^2 , and all 8 are proper. Hence there are 16 proper representations of pq as a sum of two squares. But if $p=q$, we may take $c=a$, $d=b$. For the lower signs, the final number in (5) is zero, and the resulting representation p^2+0 of p^2 is not proper. This illustrates and makes plausible the important theorem that a product of powers of k distinct primes each of the form $4n+1$ has exactly 2^{k+2} proper representations by x^2+y^2 .

The number of all representations of a positive odd integer m by x^2+y^2 is the quadruple of the excess of the number of divisors of the form $4n+1$ of m over the number of divisors of the form $4n+3$ of m .

Hermite's method is not restricted to x^2+y^2 . If p is a prime of either of the forms $8n+1$ or $8n+3$, then $(-2/p) = +1$, and $t^2+2=pq$ is solvable for integers t, q . Then f is equivalent to the single reduced form $(1, 0, 2)$ of discriminant -8 . Hence p is represented by x^2+2y^2 . Again, if $p=3n+1$ is a prime,

$$(-3/p) = (p/3) = +1,$$

and $t^2+3=pq$ is solvable; hence p is represented by x^2+3y^2 . The method applies directly when no two reduced forms have the same divisor, i.e., the greatest common divisor of the three coefficients of a form.

But the two reduced forms $(1, 0, 5)$ and $(2, 2, 3)$ of discriminant -20 have the same divisor 1. The primes p of the forms $20n+1$, 3, 7, 9 are the only ones distinct from 2 and 5 for which $(-5/p) = +1$. Hence any product m of powers of primes of these four types is represented by one of the reduced forms $g=x^2+5y^2$, $h=2x^2+xy+3y^2$. To decide which one, note that $g=m$ gives $(m/5) = +1$, while $h=m$ gives

$$2m = (2x+y)^2 + 5y^2, \quad (2m/5) = 1, \quad (m/5) = (2/5) = -1.$$

Hence the representation is by g if $m=5k \pm 1$, but by h if $m=5k \pm 3$.

Positive Ternary Quadratic Forms.—If we write

$$F = ax^2 + by^2 + cz^2 + 2xyz + 2sxz + 2txy, \quad (1)$$

$$d = \begin{vmatrix} a & t & s \\ t & b & r \\ s & r & c \end{vmatrix} \quad \begin{aligned} L &= ab - t^2, \\ M &= ar - ts, \\ N &= ac - s^2, \end{aligned}$$

then d is called the *determinant* of the ternary form F . For real values of the coefficients and variables, F is called a *positive form* if every value of F is ≥ 0 and if $F=0$ only when $x=y=z=0$. We have

$$aF - (ax+ty+sz)^2 = f = Ly^2 + 2Myz + Nz^2, \quad (2)$$

$$Lf = (Ly+Mz)^2 + adz^2, \quad LN - M^2 = ad. \quad (3)$$

Hence if a, L , and d are all positive, F is a positive form. The converse is easily proved.

Let ϕ be any positive ternary quadratic form of determinant d with integral coefficients (those of cross products being even as in F). Let a be the least positive integer which is represented by ϕ . The main theorem states that ϕ is equivalent to a form (1) such that (2) is a reduced binary form of discriminant $-4ad$, and such that $-a < 2s \leq a$, $-a < 2t \leq a$. Since F and hence also ϕ represents b , we have $a \leq b$. Thus

$$a^2 \leq ab = L + t^2 \leq L + \frac{1}{4}a^2, \quad 3a^2 \leq 4L.$$

Our earlier work on reduced binary forms f gives $3L^2 \leq 4ad$.

Hence

$$a \leq \frac{1}{3} \sqrt[3]{d}. \quad (4)$$

Thus when d is given, there is only a finite number of sets of integers a, s, t satisfying our inequalities. We saw that there is only a finite number of reduced binary forms f of given discriminant $-4ad$. Hence there is only a finite number of classes of positive ternary quadratic forms of given determinant.

Let $a=1$. Then $s=t=0$, and (2) becomes $F-x^2=f$. The substitution which merely changes the signs of x and y is of determinant 1 and merely changes the sign of M . Hence we may take $M \geq 0$.

Let $d=1$ or 3. Then $a=1$ by (4). Applying also the conclusions found in Examples 1 and 2 under binary quadratic forms, we have the following theorem: Every positive ternary quadratic form of determinant 1 is equivalent to $x^2+y^2+z^2$; every one of determinant 3 is equivalent to $P=x^2+y^2+3z^2$ or

$$Q=x^2+2y^2+2yz+z^2.$$

We are now in a position to discuss one of the most useful theorems in the theory of numbers: If a is any positive integer not of the form $4^k(8n+7)$, then a is a sum of three squares having no common factor > 1 . Complicated proofs were first given by Legendre in 1798 and by Gauss in 1801. The simplest proof is that by Dirichlet in 1850. It employs a positive form (1) whose determinant d is unity. Take $s=1$, $t=0$. Then $d=a\Delta-b$, where Δ denotes $bc-r^2$. Let a be double an odd integer. There are infinitely many primes in any arithmetical progression whose first term and common difference are relatively prime. Hence we can choose a positive integer l so that $b=4nl+a-1$ is a prime. Take $\Delta=4l+1$. Then $(-\Delta/b) = +1$. Hence there is an integer r such that $(r^2+\Delta)/b$ is an integer c . The resulting positive form (1) of determinant unity must be equivalent to $X^2+Y^2+Z^2$ by our previous theorem. Hence $X=\alpha x+\dots$, $Y=\beta x+\dots$, $Z=\gamma x+\dots$ have integral coefficients whose determinant is unity. Hence $a=\alpha^2+\beta^2+\gamma^2$, where α, β, γ are integers with no common factor > 1 . The proof is similar for the remaining numbers a .

We saw that all positive ternary forms of determinant 3 are equivalent to P or Q . To show that P represents every positive integer a not divisible by 3, Dirichlet used (1) with $s=1$, $t=0$ and $b=5$ a multiple of 8. It is easily verified that $Q-5$ is never divisible by 8. Since (1) is of determinant 1 and represents b , while Q does not represent b , (1) must be equivalent to P . But he did not prove that P represents every positive integer $9n+3$.

Its proof requires a serious modification of his method and was given, along with a complete study of various new ternary forms, in several papers published in America in 1927. The complete theorem for $P = x^2 + y^2 + 3z^2$ is that a positive integer can be represented by P if and only if it is not of the form $q^k(qn+6)$.

The forms P and $x^2 + y^2 + z^2$ are called *regular* since all the positive integers not represented by one of them coincide with all the positive integers in certain arithmetical progressions. The form $g = x^2 + y^2 + 10z^2$ is regular with respect to even integers since it represents no number $4^k(16n+6)$, but represents all the remaining even integers. However, g is irregular with respect to odd integers. It was proved in 1927 that if k is any one of the odd integers 3, 7, 21, 31, 33, 43, 67, 79, 87, 133, 217, . . . not represented by g , then every arithmetical progression which contains k will contain integers represented by g . Only a few forms are regular.

Positive Quaternary Quadratic Forms.—One of the most remarkable theorems is that every positive integer p is a sum of four squares. Diophantus seems to have recognized this fact. In 1659 Fermat stated that he possessed a proof by descent from p to smaller numbers, and a short proof of this kind was published in 1924. Euler tried for 40 years to find a proof. The first proof published was that by Lagrange in 1772. The next year Euler gave a much simpler proof which is still quoted in text-books.

Every p is represented by each of $x^2 + y^2 + z^2 + su^2$ ($s = 1, \dots, 7$). Except when $p = 4^k(8n+7)$, we may take $u = 0$ and apply the earlier result that p is a sum of three squares. We shall next prove that $8n+7$ is represented, whence $2^kx, \dots, 2^ku$ give a representation of $4^k(8n+7)$. We have only to exhibit a value of u for which $8n+7-su^2$ is positive and not of the form $4^k(8m+7)$ and hence is a sum of three squares. For $s = 1, 2, 4, 5$, or 6, take $u = 1$. For $s = 3$, take $u = 1$ or 2 according as $n = 0$ or $n > 0$. For $s = 7$, take $u = 1$ if $n = 0, 1$, or 2; but take $u = 2$ if $n \geq 3$.

The same proof applies to $x^2 + 2y^2 + 2z^2 + su^2$. A similar proof shows that every p is represented by each of

$$\begin{aligned} x^2 + y^2 + 2z^2 + lu^2 & \quad (l = 2, \dots, 14), \\ x^2 + y^2 + 3z^2 + mu^2 & \quad (m = 3, 4, 5, 6), \\ x^2 + 2y^2 + 3z^2 + nu^2 & \quad (n = 3, \dots, 10), \\ x^2 + 2y^2 + 4z^2 + qu^2 & \quad (q = 4, \dots, 14), \\ x^2 + 2y^2 + 5z^2 + ru^2 & \quad (r = 6, \dots, 10). \end{aligned}$$

Besides these 54 forms there is no new form of the type $ax^2 + by^2 + cz^2 + du^2$ which represents every p when a, b, c, d are positive integers. This is easily verified by using the values 1, 2, 3, 5, 6, 7, 10, 14, 15 of p .

Recently the problem has been completely solved for forms q involving also products like xy . The main point in the solution is a simple application of the principles which have been developed above in detail. It will be explained for the important typical case $q = u^2 + \tau$ where τ is a positive ternary quadratic form. Let m be the least positive integer represented by τ . Unless m is 1 or 2, q would not represent 2. Let $m = 1$ and let d denote the determinant of 2τ . The main theorem quoted under ternary forms shows that 2τ (whose minimum is $a = 2$) is equivalent to a form $2T = F$ such that $4T - X^2$ is the reduced binary form f in (2), where $X = 2x + ty + sz$, $t = 0$ or 1, $s = 0$ or 1. By hypothesis, $q = u^2 + T$ represents all positive integers. Hence $Q = 4q = 4u^2 + X^2 + f$ represents all positive multiples of 4. The positive minimum of the reduced f is L . If $L > 12$, $Q = 12$ requires that $f = 0$. But $12 = 4u^2 + X^2$ is impossible in integers. Hence $L \leq 12$. Since the coefficients of y^2 in $X^2 + f$ and $4T$ are equal, $L^2 + L$ is a multiple of 4. Hence the only possible values of L are 4, 8, 12, 3, 7, 11. In these respective cases the least positive multiple of 4 not represented by $4u^2 + X^2 + Ly^2$ (or Q with $s = 0$) is found to be $l = 28, 56, 24, 24, 84, 88$, respectively. Since Q shall represent l , we have $f \leq l$ for certain integers y and z such that $s \neq 0$. Then (3) evidently implies that $4d \leq Ll$. Hence there is a limited number of values of d , and therefore of reduced forms f of discriminant $-8d$. This proves that the number of forms T is finite.

In addition to the above 54 forms involving only squares, there

are exactly 299 further forms $u^2 + T$ which represent all positive integers. If we multiply them by 4, 8, 12, 28, or 44, we may complete the squares and obtain forms involving only squares. The following are samples of the resulting equivalent theorems: If $r = 4m - 1$ or $4m - 2$, $m = 1, \dots, 7$, then $x^2 + y^2 + z^2 + ru^2$ represents all positive multiples of 4. If $k = 1, \dots, 6$, and $s = 0$ or 1, then $x^2 + 3y^2 + 3z^2 + 4(3k - s)u^2$ represents all positive multiples of 12. If $3 \leq k \leq 22$, $s = 0$ or 1, $0 \leq M \leq 5$, with $M + s$ even, then $x^2 + 11y^2 + 11z^2 + (44k - Ls - M^2)u^2$ represents all positive multiples of 44.

The number of representations of any positive integer N as a sum of four squares is $8s$ or $24s$, according as N is odd or even, where s is the sum of the positive odd divisors of N . If N is odd, the number of representations of $4N$ as a sum of four odd squares is $16s$.

Let w be odd and S be the sum of its divisors not divisible by 3. The number of representations of $2^r w$ by $x^2 + y^2 + 3z^2 + 3u^2$ is $4(2^{r+1} - 3)S$ if $r > 0$, but is $4S$ if $r = 0$.

Analogous theorems have been found for many forms whose four coefficients are all products of powers of 2 and 3, or when each coefficient is 1 or 5. Also the number of proper representations was found.

Waring's Problem.—Without proof, Waring stated in 1770 that every positive integer is a sum of 9 integral cubes ≥ 0 , a sum of 19 biquadrates, etc. In 1859 Liouville employed an identity equivalent to

$$6(x_1^2 + x_2^2 + x_3^2 + x_4^2)^2 = \sum (x_i + x_j)^4 + \sum (x_i - x_j)^4, \quad (1)$$

summed for $i, j = 1, \dots, 4$; $i < j$. Since every integer $n \geq 0$ is a sum of four squares, this proves that $6n^2$ is a sum of 12 biquadrates. Every integer $p \geq 0$ is of the form $6q + r$, where r is one of 0, 1, . . . , 5 and is evidently a sum of five biquadrates 0 or 1. Since $q = n_1^2 + \dots + n_4^2$, $6q$ is a sum of 4×12 biquadrates. Hence every p is a sum of 53 biquadrates.

Later writers gradually reduced this limit 53 to 37. The latest result is that every p is a sum of 17 biquadrates and 10 doubles of biquadrates.

That every p is a sum of nine integral cubes ≥ 0 was first proved by Wieferich in 1909; a gap in his proof was first filled by Kempner in 1912. A simpler proof was given by Dickson in 1927, who proved also that, if $t \leq 23$, every p is represented by $tx^3 + C_8$, where C_8 is a sum of 8 integral cubes ≥ 0 , and $x \geq 0$; also by $kx^3 + 2y^3 + C_7$ if $k \leq 34$, $k \neq 10, 15, 20, 25, 30$; also by $lx^3 + 3y^3 + C_7$ if $l \leq 9$, $l \neq 5$; and for $p < 40,000$ by $x^3 + y^3 + 2z^3 + 2u^3 + 3v^3$.

In 1909 Hilbert proved that every p is a sum of N_k positive or zero k th powers. The long proof gives no clue as to the value of the finite number N_k . By means of a fivefold integral, he proved the existence of an identity, of type (1), which expresses $M(x_1^2 + x_2^2 + x_3^2 + x_4^2)^k$ as a sum of $2k$ th powers of linear functions of x_1, x_2, x_3, x_4 with integral coefficients. Here M is a positive integer depending on k . Later writers established this identity by algebraic methods.

In 1913 Baer gave $N_5 = 58$ and $N_6 = 478$, which are less than earlier limits. Wieferich gave $N_7 = 3,806$. Writing $(1, r, 8_s)$ for a sum of r sixth powers and the products of s sixth powers by 8, Dickson proved that every p is represented by each of the forms

$$(1_{115}, 8_{108}), (1_{178}, 8_{99}), (1_{10}, 2_{90}, 3_{72}, 4_{18}).$$

Identities of Hilbert's type leading to explicit finite values of N_k were given by A. Hurwitz for $k = 8$, by I. Schur for $k = 10$, and by Kempner for $k = 12$ and 14.

By intricate analytic investigations, Hardy and Littlewood recently obtained remarkable results. First they gave a new proof that N_k is finite. Next, they proved that, for all sufficiently large numbers, $N_k \leq (k-2)2^{k-1} + 5$ (9 cubes, 21 biquadrates, 53 fifth powers, etc.). Finally, when $k \geq 4$ they obtained in 1925 a limit involving logarithms which gives the best results to date: Every sufficiently large integer p is a sum of 19 biquadrates, 41 fifth powers, 87 sixth powers, 193 seventh powers, 425 eighth powers, 949 ninth powers, or 2,113 tenth powers. No determination was made for the limit beyond which p must

lie, but it would be excessively large. Landau simplified this theory in his 1927 text.

In 1909 Landau proved that all sufficiently large integers p are sums of 8 cubes. That this holds if $p \geq 23 \times 10^{14}$ was proved by Baer by technical results in the analytic theory of primes. For $l=1, \dots, 5$, Dickson proved that $lx^3 + C_l$ represents all sufficiently large integers.

Sums of Values of a Polynomial.—In 1636 Fermat stated that every positive integer p is a sum of $m+2$ polygonal numbers $\frac{1}{2}m(x^2-x) + x$ of order $m+2$. For $m=1$, the latter is a triangular number $\frac{1}{2}x(x+1)$ and is the number of shot arranged in a triangle with x shot in the base. That every p is a sum of three triangular numbers is equivalent to the fact that $8p+3$ is a sum of three odd squares $(2x+1)^2$. For $m=2$, the theorem states that every p is a sum of four squares. Cauchy gave the first proof in 1815, and showed that all but four of the polygonal numbers may be chosen from the special ones 0 and 1. He employed the following lemma: If a and b are positive odd integers and if b lies between $\sqrt{(3a-2)}-1$ and $\sqrt{4a}$, there exist four integers l, u, v, w , each ≥ 0 , such that

$$a = l^2 + u^2 + v^2 + w^2, \quad b = l + u + v + w.$$

When a and b are even, this holds if also $a - b^2/4$ is a sum of three squares.

In 1921 Kampke considered any polynomial $P(x)$ with rational coefficients whose values are integers ≥ 0 for every integer $x \geq 0$, and proved that every integer $p \geq 0$ is a sum of s such values of $P(x)$ and e numbers 0 or 1, where s and e are finite integers depending on $P(x)$, but not on p . This existence proof gives no clue to the values of s and e . He also generalized Cauchy's lemma from 2 to n simultaneous equations

$$l_k = x_1^k + \dots + x_N^k \quad (k=1, \dots, n),$$

where l_2, \dots, l_n lie between specified limits, and N is to be chosen.

The complete solution for quadratic functions was given by Dickson in 1928. Consider $f(x) = \frac{1}{2}m(x^2-x) + tx + c$, where m, t, c are integers and $m > 0, t > 0, c \geq 0$. A quadratic function takes integral values ≥ 0 for every integer $x \geq 0$ if and only if it is either $f(x)$ or $f(x-k)$ with $k \geq 1, m \geq t$. Since c is the least such value of $f(x-k)$, sc is the least sum of s values. The problem is to find the least integer e_s such that every integer $\geq sc$ is a sum of s values of $f(x-k)$ for integers $x \geq 0$ and e_s numbers 0 or 1. We may take $c=0$ without loss of generality. First, let $s \geq 5$. If $k=0$, then $E_s = e_s + 1$ is t or $m - (s-3)t$, according as $m < (s-2)t$ or not. If $k > 0$ and $m \leq 2t$, then E_s is t or $m - (s+1)t$, according as $m < (s+2)t$ or not. When $m < 2t$, write q for $m-t$. If $k \geq 2$, E_s is q or $t-3q$, according as $t \leq (s+1)q$ or not. When $k=1$, $E_s = q$ if $t \leq 3q$, $E_s = t-2q$ if $t \geq 3q$. But if $k=1, s \geq 6$, $E_s = q$ or $t - (s-2)q$, according as $t \leq (s-1)q$ or not. We now know the minimum L for all $s \geq 5$ of the number $s + e_s$ of summands. Whenever $4 + e_4$ is less than L , it is exactly $L-1$. The minimum of all $s + e_s$ for $s \geq 1$ is L or $L-1$ except when $k=0, m \leq t$, and then is $L-2$.

Every integer $p \geq 0$ has been recently proved to be a sum of ten pyramidal numbers $\frac{1}{6}(x^3-x)$ for integers $x \geq 0$; also a sum of nine if p is sufficiently large.

If in the formula for polygonal numbers we employ negative as well as positive integral values of x , we obtain the generalized polygonal numbers. Every positive integer is a sum of N generalized polygonal numbers of order k , where $N=3$ for $k=3, 5$ or 6; $N=4$ for $k=4, 7$ or 8; $N=k-4$ for $k > 8$.

Consider the positive binary quadratic forms q and the integers s such that every positive integer p is a sum of s values of q . The case $p=1$ requires that q shall represent 1. Hence we may take $q = x^2 + axy + by^2$, $a=0$ or 1. Then each p is a sum of four values of q with $y=0$. Thus the cases $s=2$ and $s=3$ alone are interesting. Whether a is 0 or 1, every p is a sum of two values of q if and only if $b=1, 2$, or 3, and a sum of three values of q if and only if $b=1, \dots, 7$.

ALGEBRAIC NUMBERS

Failure of Expected Laws.—The roots of an equation $ax^n + bx^{n-1} + \dots = 0$ having integral coefficients are called algebraic numbers. If $a=1$, the roots are *integral algebraic numbers*; examples are $\sqrt{5}, \sqrt[3]{5}$. Prior to a lengthy controversy in 1847, it was regarded as self-evident that the laws of divisibility which hold for whole numbers continue to hold also for integral algebraic numbers. Fundamental for mathematics was the recognition of the falsity of this intuition and the invention of "ideals" serving to restore those laws of divisibility.

A typical example is the set S of all quadratic integers $a+b\theta$, where $\theta = \sqrt{-5}$, while a and b are whole numbers. By an indecomposable number n of this set S we mean one having no factor in S other than $n, -n, 1, -1$. If $2+\theta = (x+y\theta)(z+w\theta)$, where x, y, z, w are whole numbers, we multiply by the like equation having $-\theta$ in place of θ , and get $9 = (x^2+5y^2)(z^2+5w^2)$. But $x^2+5y^2=3$ is evidently impossible in whole numbers. Hence we may take $x^2+5y^2=1$, whence $x+y\theta = \pm 1$. The same discussion applies also if we replace $2+\theta$ by $2-\theta$ or 3. Hence $9 = 3 \cdot 3$ and $9 = (2+\theta)(2-\theta)$ give two factorizations of 9 into indecomposable numbers of S . The law of unique factorization of whole numbers into primes therefore fails for numbers of S . Since the indecomposable number 3 divides the product 9 of $2+\theta$ and $2-\theta$ without dividing either of them, we have a second failure in S of laws of ordinary primes. A third more astonishing failure in S of the laws of arithmetic is the absence in S of a greatest common divisor of 9 and $t=3-6\theta$; their only common divisors are $\pm 1, \pm 3$ and $\pm(2-\theta)$, no one of which is divisible by the remaining five.

Ideals.—These laws are restored by the introduction of ideals, first defined intangibly in special cases by Kummer in 1847, and later in complete generality and clearness by Dedekind. To any number μ of our set S corresponds uniquely the totality $\rho\mu$ of its multiples, where ρ ranges over all numbers of S . This totality is called the *principal ideal* (μ) and evidently has the following two properties: (a) The sum and difference of any two numbers of an ideal are themselves numbers of the ideal. (b) Every product of a number of an ideal by a number of S is a number of the ideal. Any set of numbers of S is called an *ideal* if it has these two properties and is not composed exclusively of the number zero.

When x and y range independently over all whole numbers, the totality $x\xi + y\eta$ is denoted by $[\xi, \eta]$. It evidently has property (a). To show that $\beta = [3, 1+\theta]$ is an ideal, it remains to verify that it has property (b). This will follow if we show that 3ρ and $(1+\theta)\rho$ belong to β for every ρ in S . But $\rho = a+b\theta$, where a and b are whole numbers, and

$$3\rho = 3(a-b) + 3b(1+\theta), \quad (1+\theta)\rho = -6b + (a+b)(1+\theta)$$

are numbers in β . Since we may replace θ by $-\theta$ in this proof, we conclude that also $\alpha = [3, 1-\theta]$ is an ideal.

If L ranges over the numbers of an ideal λ and if M ranges over those of an ideal μ , then the set composed of the products LM and all their sums and differences is seen to have properties (a) and (b) and hence is an ideal, called the product of λ and μ , and denoted by either $\lambda\mu$ or $\mu\lambda$. In particular,

$$\alpha\beta = [9, 3+3\theta, 3-3\theta, 1-\theta^2=6] = [3, 3\theta] = (3).$$

Similarly, $\beta^2 = (2-\theta)$ and hence $\alpha^2 = (2+\theta)$.

To remove the above difficulties concerning numbers 9, 3, $\dots, t=3-6\theta$ of S , we pass to the uniquely corresponding principal ideals (9), (3), $\dots, (t)$. Now

$$(9) = (3)(3) = \alpha^2\beta^2 = (2+\theta) \cdot (2-\theta),$$

and we have the single factorization $(9) = \alpha^2\beta^2$ instead of the former two factorizations of 9. Finally, $\gamma = [7, 3+\theta]$ is an ideal such that $\beta\gamma = (1-2\theta)$, so that (9) and $(t) = (3)\beta\gamma = \alpha\beta^2\gamma$ have the greatest common ideal divisor $\alpha\beta^2$.

If an ideal is different from the principal ideal (1) and if it is divisible by no ideal other than itself and (1), it is called a *prime ideal*. It is readily proved that every ideal which is not a prime can be expressed in one and but one way as a product of (a finite number of) prime ideals. Hence the laws of factorization in

arithmetic hold for our ideals. Since α, β, γ are prime ideals, the above three difficulties have been completely removed.

Classes of Ideals.—Two ideals ρ and σ are called equivalent if there exist principal ideals (r) and (s) such that $\rho(r) = \sigma(s)$. If also ρ is equivalent to τ , with $\rho(q) = \tau(t)$, then σ is equivalent to τ since $\sigma(sq) = \rho(r)(q) = \tau(tr)$. Hence all ideals equivalent to a given one are equivalent to each other and are said to form a class of ideals.

Evidently any two principal ideals are equivalent. If σ is equivalent to the principal ideal (1) , so that $\sigma(s) = (r)$, the number r of the product $\sigma(s)$ is in (s) , whence r is divisible by s and $\sigma = (r/s)$. Hence the principal class contains all the principal ideals and no others.

For the above set S determined by $\theta = \sqrt{-5}$, we readily specify the classes of ideals. If (α) is any principal ideal, we have $\alpha = m(x + y\theta)$, where x and y are relatively prime integers. We can choose integers r and s such that

$$\begin{vmatrix} x & -y \\ s & -r \end{vmatrix} = sy - rx = 1.$$

Hence we can solve $\alpha x - y\alpha\theta = u$, $\alpha x - r\alpha\theta = v$, and express α and $\alpha\theta$ as linear functions of u and v with integral coefficients. This proves that $(\alpha) = [\alpha, \alpha\theta]$ is identical with $[u, v]$. But $u = ma$, $a = x^2 + 5y^2$, $v = m(b + \theta)$, $b = sx + 5ry$. Also

$$b^2 + 5 = b^2 + 5(sy - rx)^2 = a(s^2 + 5r^2).$$

Hence all principal ideals are given by

$$[ma, m(b + \theta)], \quad (b^2 + 5)/a = \text{integer}, \quad (\text{I.})$$

in which a is properly represented by $x^2 + 5y^2$.

Since 2 is not such a value of a , $\rho = [2, 1 + \theta]$ is not a principal ideal. Hence the system S was actually enlarged by the introduction of ideals. In some other systems Σ , every ideal is a principal ideal and then the laws of divisibility of whole numbers hold for Σ since they hold for the essentially equivalent set of all ideals. This happens for systems Σ of numbers involving $\sqrt{-k}$ when $k = 1, 2, 3, 7, 11, 19, 43, 67, 163$, but for no further positive values $< 1,500,000$ of k lacking square factors, and holds for many negative values of k .

For S all ideals equivalent to ρ are readily shown to be of type (I.) where now a is properly represented by $f = 2x^2 + 2xy + 3y^2$. Moreover, all ideals are given by (I.). Consider any such ideal and write l for the final integer in (I.). Then $ax^2 + 2bxy + ly^2$ is of discriminant $4(b^2 - al) = -20$ and hence is equivalent to one of the two reduced forms $x^2 + 5y^2$ or f of discriminant -20 . Thus a is represented by one of them. Hence there are exactly two classes of ideals.

This example illustrates the identity of the problems to find the number of classes of binary quadratic forms of negative discriminant d and the number of classes of ideals for the system of quadratic integers determined by \sqrt{d} . For a positive d , a similar result holds if in our criterion $\rho(r) = \sigma(s)$ for the equivalence of ideals ρ and σ , we impose the restriction that the norm of r/s is positive (narrow equivalence of ideals).

Arithmetics of Algebras.—We shall now discuss an important generalization of algebraic numbers. A quaternion $q = a + bi + cj + dk$ was called integral by Lipschitz in his *Untersuchungen über die Summen von Quadraten* (Bonn, 1886) if and only if a, b, c, d are integers. This natural definition led to serious difficulties and has been discarded. More fortunate was A. Hurwitz in his important book, *Zahlentheorie der Quaternionen* (1919), who called q integral not only when a, b, c, d are integers, but also when all four are halves of odd integers. Two such integral quaternions have a greatest common right (or left) divisor. The resulting perfect arithmetic of quaternions leads to simple proofs, as well as interpretations, of the main facts about the number of representations of integers as sums of four squares. Du Pasquier applied Hurwitz's definition unchanged to many further linear algebras and found that they usually do not possess integral numbers.

The latter unfortunate conclusion is avoided by the new definition given by Dickson in his *Algebras and their Arithmetics*

(Chicago, 1923), where general theorems were obtained for the first time. In his *Algebren und ihre Zahlentheorie* (Zürich, 1927), he gave the following simpler, but equivalent, definition: Let A be any rational associative algebra containing 1. Consider a set S of numbers in A each satisfying an algebraic equation with integral coefficients and having 1 as leading coefficient, and such that the sum, difference and product of any two numbers of S are all numbers of S . Let S contain 1. Then if S is not contained in a larger such set, its numbers are called the *integral numbers* of algebra A . In case A is an algebraic field, our integral numbers become the classic integral algebraic numbers of A . Again, if A is the algebra of quaternions, our integral numbers become the integral quaternions of Hurwitz (see QUATERNIONS).

The applications include a complete theory of the number of (all or only proper) representations by $x^2 + y^2 + tz^2 + tu^2$ for $t = 1, 3, -3$, or 7 , and by various forms having cross-products; and the complete solution in integers $x, \dots, u, \delta_1, \dots, \delta_k$ of $Q = \delta_1 \delta_2 \dots \delta_k$, where Q is any one of the mentioned quadratic forms. For example, $q = a + bi + cj + dk$ is said to have the co-ordinates a, b, c, d and norm $N(q) = a^2 + b^2 + c^2 + d^2$. Then all integral solutions of $x^2 + y^2 + z^2 + u^2 = \delta_1 \dots \delta_k$ are derived from

$$x + yi + zj + wk = d_1 \dots d_k, \quad \delta_1 = N(d_1), \dots, \delta_k = N(d_k)$$

if we take d_1, \dots, d_k to be arbitrary quaternions with integral co-ordinates. If we take $k = 2$ and express $w^2 - v^2$ as a product $\delta_1 \delta_2$ of two integers in all ways, we obtain all integral solutions of $x^2 + y^2 + z^2 + u^2 + v^2 = w^2$ by means of quaternions.

Let M be an n -rowed square matrix whose n^2 elements x_{ij} are variables. Denote its determinant by D . Then all integral solutions $x_{ij}, \delta_1, \dots, \delta_k$ of $D = \delta_1 \delta_2 \dots \delta_k$ are derived from

$$M = d_1 d_2 \dots d_k, \quad \delta_1 = |d_1|, \dots, \delta_k = |d_k|$$

if we take d_1, \dots, d_k to be n -rowed matrices whose elements are arbitrary integers. For $n = k = 2$, this yields all integral solutions of $x^2 + y^2 + z^2 + u^2 + v^2 = w^2$. Instead of integers we may employ integral algebraic numbers.

MISCELLANEOUS TOPICS

Perfect Numbers.—A number is called perfect if it is equal to the sum of its divisors smaller than itself. For example, $6 = 1 + 2 + 3$ is the first perfect number. No odd perfect number is known, but it has not been proved that none exist. It is easily proved that every even perfect number is of the form $2^{p-1}(2^p - 1)$. Euclid (*Elem.*, ix. 36) proved that the latter is a perfect number if $2^p - 1$ is a prime. Without justification, Mersenne stated in 1644 that the first 11 values of p for which $2^p - 1$ is a prime are 2, 3, 5, 7, 13, 17, 19, 31, 67, 127, 257. It is now known that 67 should be omitted, and 61, 89, 107 included; while the only cases in doubt are 137, 139, 149, 157, 167, 193, 199, 227, 229, 241, 257.

Galois Imaginaries.—Under the topic quadratic residues, we found that there is no integer x such that $x^2 - 3$ is divisible by 7. Nevertheless, in 1830 Galois invented imaginaries α having this property. Their use was later justified by employing the 49 residues $\alpha x + b$ ($a, b = 0, 1, \dots, 6$) obtained from all polynomials in x with integral coefficients by suppressing polynomial multiples of both $x^2 - 3$ and 7. The theory is given completely in Dickson's *Linear Groups* (Leipzig, 1901). An account in French occurs in Serret's *Algèbre*.

Modular Invariants.—For example, consider

$$l = \begin{vmatrix} x^p & y^p & z^p \\ x^p & y^p & z^p \\ x & y & z \end{vmatrix}, \quad L = \begin{vmatrix} X^p & Y^p & Z^p \\ X^p & Y^p & Z^p \\ X & Y & Z \end{vmatrix},$$

where p is a prime. If x, y, z are linear functions of X, Y, Z with integral coefficients whose determinant is d , then $l - dL$ is divisible by p . We therefore call l a *modular invariant*. But l has the factor x . It follows that l differs by a multiple of p from the product of all linear functions of x, y, z whose coefficients are chosen from $0, 1, \dots, p-1$ such that the first coefficient > 0 is 1. These facts hold also when l is replaced by the like deter-

minant of order n . For $n=2$, the last theorem implies Fermat's theorem.

All algebraic invariants (see ALGEBRAIC FORMS) with integral coefficients are modular invariants; but the converse is not true. The simplest theory of modular invariants is based on the modular classes of forms. For an exposition with bibliography, see Dickson's *Invariants in the Theory of Numbers* (American Mathematical Society Colloquium Lectures, 1914).

Distribution of Primes.—The number of primes is infinite (Euclid, *Elem.*, ix. 20). Any arithmetical progression $mx+n$ contains an infinitude of primes if m and n are relatively prime. The first proof is due to Dirichlet (1837), who extended the theorem to numbers $a+bi$ such that a and b are integers. He proved that $q=ax^2+2bxy+cy^2$ represents infinitely many primes if $a, 2b, c$ have no common factor. Also an infinitude are represented simultaneously by f and $mx+n$ provided the two can represent the same number and m and n are relatively prime.

For any $\epsilon > 0$ and any relatively prime integers m and n , the number of primes $mx+n$ which lie between z and $(1+\epsilon)z$ increases to infinity with z . Take $\epsilon=1$. Hence if the integer y exceeds a certain limit (6, in fact), there exists at least one prime p such that $\frac{1}{2}y < p \leq y-2$; this is known as Bertrand's postulate (1845).

In 1742 Goldbach conjectured that every positive even integer is a sum of two primes. This has been verified to 10,000, but not yet proved. Subject to assumptions about the roots of Dirichlet's function L , Hardy and Littlewood recently proved that all sufficiently large even integers e are sums of three odd primes; also if N of the first m even positive integers are not sums of two odd primes, N/m approaches zero as m increases indefinitely. By developing their first proof, Lucke showed that every $e > (3.6)10^{32}$ is a sum of three odd primes.

Tchebychef proved in 1852 that, if x is sufficiently large, the number $\pi(x)$ of primes $\leq x$ is between $0.92129Q$ and $1.10555Q$, where $Q = x/\log x$. By use of Riemann's function $\zeta(s) = \sum n^{-s}$, Hadamard and de la Vallée-Poussin proved independently in 1896 that the sum of the natural logarithms of all primes $\leq x$ is equal to x asymptotically. This implies the important result that $\pi(x)$ is asymptotic to Q . If we integrate $du/\log u$ first from 0 to $1-\delta$ and second from $1+\delta$ to x , add the results, and take the limit of the sum for $\delta=0$, we get the integral logarithm of x , denoted by $Li(x)$. It is asymptotic to Q and hence to $\pi(x)$. But $Li(x)$ represents $\pi(x)$ more exactly than does Q or $Q+x/\log x$, etc.

All these subjects are treated exhaustively in Landau's *Handbuch der Lehre von der Verteilung der Primzahlen* (1909).

Partitions.—There are just two partitions $1+5$ and $2+4$ of 6 into two parts chosen from 1, 2, 3, . . . without repetition; there is the third partition $3+3$ if repetition is allowed. If we exhibit the partition $2+4$ as $\{\begin{smallmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \end{smallmatrix}\}$ and then sum the columns instead of the lines, we get the partition $2+2+1+1$. If we repeat the process on the latter, we return to $4+2$. This proves that the number of partitions of n into m parts is equal to the number of partitions of n in which m is the largest part. Taking $m=1, \dots, k$, we conclude that the number of partitions of n into not more than k parts is equal to the number of partitions of n with no part greater than k .

The number of partitions of n into m parts chosen without repetition from the distinct positive integers c_1, c_2, \dots, c_r is the coefficient of $x^n z^m$ in the expansion of the product $(1+x^{c_1}z) \dots (1+x^{c_r}z)$. Next, the coefficient of $x^n z^m$ in the series giving the expansion of $(1-x^{c_1}z)^{-1} \dots (1-x^{c_r}z)^{-1}$ is the number of partitions of n into m parts chosen from c_1, \dots, c_r , repetitions allowed.

For $D=(1-x)(1-x^2) \dots (1-x^m)$, the coefficient of x^n in $1/D$ is the number (n, m) of partitions of n into parts $\leq m$ not necessarily distinct. The relation $(n, m) = (n, m-1) + (n-m, m)$ serves to compute (n, m) .

There are important applications of Sylvester's theorem (1855) concerning the number Q of partitions of n into distinct positive integers c_1, \dots, c_r , repetitions allowed, whence Q is the number of sets of integral solutions ≥ 0 of $c_1 x_1 + \dots + c_r x_r = n$. Then

$Q = \sum W_q$, where W_q is the coefficient of x/t in the development in ascending powers of t of

$$\sum p^{-n} e^{nt} \prod_{j=1}^r (1 - p^{c_j} e^{-tc_j})^{-1},$$

in which the summation extends over the various primitive q th roots p of unity. Thus $W_q = 0$ unless q divides some c_i .

Binary Quadratic Forms.—The form $f=(a, b, c)$ of positive discriminant d is called reduced if the roots of $aw^2+bw+c=0$ are of opposite signs, if one root ω_1 is numerically <1 , and if the other root is numerically >1 . Although every form is equivalent to a reduced form and the number of reduced forms of discriminant d is finite, usually each reduced form is equivalent to several other reduced forms, and the number of the latter depends upon the periodicity of the continued fraction for ω_1 . There is also another reason why the theory is more complicated than that for negative discriminants (see the topic positive binary quadratic forms). When $d > 0$, the number of linear transformations with integral coefficients which leave f unaltered (called automorphs of f) is infinite, in fact one for each set of integral solutions t, u of the Pellian equation

$$t^2 - du^2 = 4\sigma^2, \quad (1)$$

where σ is the divisor of f . The difficult point is to prove the existence of solutions T, U in least positive integers such that if t, u be any further solution in positive integers then $t > T, u > U$. It is then easily proved that all sets t, u of integral solutions are given by

$$\frac{t+u\sqrt{d}}{2\sigma} = \pm \left(\frac{T+U\sqrt{d}}{2\sigma} \right)^k \quad (k=0, \pm 1, \pm 2, \dots).$$

Gauss and various later writers restricted attention to forms $f=(a, b, c)$ in which b is even, $b=2B$. Its discriminant is the quadruple of the determinant $D=B^2-ac$ of f . In (1), t is now even, $t=2\tau$, and we obtain the new Pellian equation $\tau^2 - Du^2 = \sigma^2$.

Many writers have obtained formulas for the number $h(D)$ of classes of forms $(a, 2B, c)$ of determinant D and divisor $\sigma=1$. To give only samples, let p be a prime of the form $4n+3$. Then

$$h(-p) = \Sigma\alpha - \Sigma\beta, \quad h(p) \log(T+U\sqrt{p}) = \log \Pi \tan \frac{k\pi}{4p},$$

where $\Sigma\alpha$ is the sum of the quadratic residues $\leq \frac{1}{2}(p-1)$ of p and $\Sigma\beta$ is that of the non-residues, while T, U give the solution of $T^2 - pU^2 = 1$ in least positive integers, and k takes those values from 1, 3, 5, . . . , $4p-1$ of which p is a non-residue.

Let N be the number of proper representations of m by $x^2+y^2+z^2$. Kronecker proved in 1860 by use of series for elliptic functions that $N=24 F(m)-12 G(m)$, where $G(m)$ is the number of classes of binary forms of determinant $-m$, while $F(m)$ is that of the forms in which at least one of a and c is odd. This is equivalent to a result due to Gauss (1801). Others found that

$$N=24 \sum_{s=1}^k \left(\frac{s}{m} \right) \text{ if } m=4k+1, \quad N=8 \sum_{s=1}^{2k+1} \left(\frac{s}{m} \right) \text{ if } m=4k+3,$$

where (s/m) is Jacobi's symbol and is zero if s and m have a common factor. (See FORMS, ALGEBRAIC.)

Positive Quadratic Forms in k Variables.—Let $N(n, k)$ denote the number of representations of n as a sum of k squares. Then $N(4r+1, 6)=125$, $N(4r+3)=-205$, with $s=\Sigma(d_1^2-d_2^2)$, where d_1 ranges over the divisors of type $4k+1$, and d_2 over the divisors $4k+3$. For m odd, $N(m, 8)=16\Sigma d^2$, where d ranges over all divisors of m , and $N(2^r m, 8)=2^{\frac{r}{2}}(8^{r+1}-15)\Sigma d^2$. While $N(4r+3, 10)=12\Sigma(d_1^4-d_2^4)$, the expressions for $N(n, 10)$ are complicated if $n \not\equiv 4r+3$. For m odd and $r > 0$,

$$N(2^r m, 12) = \frac{3}{2} \frac{1}{2} (21 + 2^{5r+1} \cdot 5) \Sigma d^5.$$

The numbers $N(n, 5)$ and $N(n, 7)$ have been expressed as sums involving Jacobi's symbol (s/n) , and in various other ways.

In a series of 18 papers in his journal for 1858-65, Liouville stated without proof many formulae and applications to the present topic. For example, he employed any function $f(x, y)$

which remains unaltered by the change of the sign of x or of y , and a given odd integer M , and a given positive integer α . Then

$$2\Sigma[f(d'-2^\alpha d, \delta'+\delta)-f(d'+2^\alpha d, \delta'-\delta)] \\ = \Sigma[2f(D, 2)+2f(D, 4)+\dots+2f(D, \Delta-1)-(D-1)f(D, 0)],$$

where the second summation extends over all factorizations $M=\Delta\alpha$ of M , and the first summation extends over all sets of odd integers d' , δ' , d , δ for which $M=d'\delta'+2^\alpha d\delta$. Let $m'=d'\delta'$, $m=d\delta$, and let $\zeta_k(t)$ denote the sum of the k^{th} powers of the divisors of t . When $f(x, y)$ is y^2 , this gives

$$\frac{1}{2}\zeta_1(M)-\zeta_1(M')=\Sigma\zeta_1(m')\zeta_1(m),$$

which is therefore the number of decompositions of $4M$ into $s+2^\alpha\sigma$, where s and σ are sums of four odd squares. Next, the choice $(-1)^{1/2}y$ for $f(x, y)$ yields the number of decompositions of $2M$ into $s+2^\alpha\sigma$, where s and σ are now sums of two odd squares. He found also the number of representations by various forms involving six squares with coefficients chosen from 1, 2, 3, 4; arithmetical proofs were given by Humbert in 1921.

Uspenskij employed any function $F(x, y, z)=F(x, -y, -z)$ such that $F(-x, y, z)=-F(x, y, z)$. He proved that

$$2\Sigma F(\delta-2i, d+i, 2d+2i-\delta)-\Sigma F(d+\delta, i, d-\delta)=T,$$

where the summation extends over all integral solutions of $m=i^2+d\delta$, $d>0$, $\delta>0$. Here $T=0$ if m is not a square, while if $m=s^2$,

$$T=2\Sigma F(2s-j, s, 2s-j)-\Sigma F(2s, s-j, 2s-2j),$$

summed for $j=1, \dots, 2s-1$. In a memoir of 1916 in Russian, he used this formula to deduce the number of representations by x^2+ay^2 for $a=1, 2, 3$; $x^2+y^2+z^2+bu^2$ for $b=1, 2, 3, 4, 5, 12$; $x^2+y^2+cz^2+cu^2$ for $c=3, 4, 5$; $x^2+2y^2+3z^2+6u^2$; many quaternary forms whose coefficients are all powers of 2;

$$x^2+y^2+z^2+u^2+v^2+dw^2 \text{ for } d=1, 2, 3;$$

$$x^2+y^2+z^2+e(u^2+v^2+w^2) \text{ for } e=2, 3;$$

$$x^2+4y^2+2z^2+2u^2+2v^2+2w^2;$$

$$x^2+4(y^2+z^2+u^2+v^2+w^2).$$

In his papers of 1925 in French, he applied the same formula to find the number of representations as a sum 2, 4, 6, 8, 10 squares, and to deduce all known and certain new relations between the numbers of classes of positive binary quadratic forms of various determinants.

The number of representations as a sum of any even number of squares was found by elliptic functions by Boulyguine in 1914-15 and by elliptic modular functions by Mordell in 1920. The same year, Hardy applied his powerful analytic methods to sums of k squares, $k\leq 8$. In 1924 Kloosterman gave exact and asymptotic formulas for the number of representations as a sum of r squares. In 1922 Siegel found an asymptotic expression for the number of representations as a sum of 5 or more squares of integers of a real quadratic field. See EQUATIONS; DETERMINANT; NUMBER; ALGEBRAIC FORMS.

NUMBER SEQUENCES. A set of numbers is said to form an ordered set if, in addition to the definition of the elements in the set, there is also given a means by which relative rank may be assigned to any two numbers of the set so that of two such numbers A and B one may say either that A precedes (is of lower rank than) B or that A follows (is of higher rank than) B . For example, the set 1, 2, 3, 4 is an ordered set. The order relation so defined is analogous to that of points on a directed line and hence the order itself may be characterized as linear. By a part of a sequence we mean an ordered subset of its elements such that every two elements in the subset have the same relative rank in it as they have in the whole set. Various types of ordered sets are known as *sequences*. Any ordered set containing only a finite number of elements is called a *finite sequence*. In this case the order may be defined by a law, as when we speak of the even positive integers less than 100 taken in order of magnitude; or it may be given by an exhibition of the objects in a given order, as when one writes the sequence 9, 7, 3, 6, 1, 8, 10. A *simply infinite sequence*, or a *simple sequence*, is an ordered set which contains no element of higher rank than all the others, while every part of it which contains an element of higher rank than all the other elements in that part is a finite sequence. Thus the positive integers in the order of their magnitude form a simply infinite sequence. But if they are taken in the order

$$1, 3, 5, 7, \dots, 2, 4, 6, 8, \dots,$$

they form not a simply infinite sequence but a combination of two such sequences. In a simply infinite sequence the elements are arranged in a countable order, that is, so that there is a first element, a second, a third, and so on. Thus a simply infinite sequence may be denoted by the symbols $u_1, u_2, u_3, \dots, u_n, \dots$, where it is understood that there is no last element in the sequence. The rational numbers between 0 and 1, taken in order of magnitude, afford an example of an ordered set which cannot be denoted by such a sequence of symbols; in fact, there is no element in this set which has a next following element in the set. This set may, however, be re-ordered so as to afford an example of a simple sequence. It is necessary that the order relation in an infinite sequence be prescribed by some norm or rule; it cannot be exhibited explicitly by a given arrangement as in the case of a finite sequence. In the course of the article other types of infinite sequences will appear.

The principle of mathematical induction may be given its most characteristic formulation with respect to simply infinite sequences. If in the case of a given simply infinite sequence it be true (1) that, if an element of the sequence possesses a given property P , the next following element also possesses the property P ; (2) that the first element in the sequence possesses this property P ; then it is true that every element in the sequence possesses the property P . For instance, if we wish to show that the numbers in the sequence 1, 1+3, 1+3+5, 1+3+5+7, ... are the square numbers 1², 2², 3², 4², ... in order, we observe that the first term in the sequence has the required property and we prove that if one term has the property the next one also has it, and then we conclude to the truth of the general proposition by aid of the principle as formulated.

Examples of Sequences.—A finite or a simply infinite sequence of numbers is said to form an *arithmetic progression* if for every pair of consecutive elements A and B of the sequence (A preceding B) the difference $B-A$ is one and the same fixed number d . If the first term is a , then the numbers of the sequence are

$$a, a+d, a+2d, a+3d, \dots$$

The n th term of the sequence and the sum of the first n terms are respectively

$$a+(n-1)d \text{ and } \frac{1}{2}n[2a+(n-1)d].$$

A sequence of numbers is said to form a *harmonic progression* if the reciprocals of its terms in order constitute an arithmetic pro-

gression. A finite or a simply infinite sequence of numbers is said to form a *geometric progression* if for every pair of consecutive elements A and B (A preceding B) the quotient B/A is one and the same fixed number r . If the first term is a then the numbers of the sequence are

$$a, ar, ar^2, ar^3, \dots$$

The n th term and the sum of the first n terms are respectively

$$ar^{n-1} \text{ and } \frac{a(1-r^n)}{1-r}.$$

Simple Infinite Sequences.—A simply infinite sequence a_1, a_2, a_3, \dots of numbers is said to be *convergent* and to form a *regular sequence* if for every positive number ϵ , however small, there exists a positive integer n such that the numerical value of $a_n - a_m$ is less than ϵ for every integer m greater than n . Regular sequences play a fundamental rôle in the development of mathematical analysis. To begin with, they furnish one of the means by which the number system may be extended from the rational domain to the domain of real numbers, and thus serve to lay the foundations on which an adequate theory of functions may be built. If, having developed the system of rational numbers (see NUMBERS), we proceed to form simply infinite sequences of rational numbers, it will be found that some such sequences have rational numbers as limits (see LIMIT), and that all such sequences having rational numbers as limits are regular in accordance with the foregoing definition, the number ϵ in the definition being taken rational in this case. It becomes desirable to extend the number system so that every regular sequence of rational numbers shall have a limit in the extended number system. This is done by taking the regular sequence of rational numbers itself to represent a definite number defined by the sequence, in accordance with a method introduced by G. Cantor (*Math. Annalen*, vol. v., 1872, and vol. xxi., 1883).

Before presenting the method of Cantor it is convenient to note some properties of regular sequences of rational numbers. Let $\{a_n\}$ be a symbol to denote the sequence a_1, a_2, a_3, \dots . If $\{a_n\}$ and $\{b_n\}$ are two regular sequences of rational numbers, then it may be shown that the sequences

$$\{a_n + b_n\}, \{a_n - b_n\}, \{a_n b_n\}, \left\{\frac{a_n}{b_n}\right\}$$

are also regular sequences, with suitable restrictions in the last case—for instance, that all the elements of $\{b_n\}$ shall be greater than some given positive number. It is natural to take as the sum, difference, product, and quotient, of two sequences $\{a_n\}$ and $\{b_n\}$ the sequences

$$\{a_n + b_n\}, \{a_n - b_n\}, \{a_n b_n\}, \left\{\frac{a_n}{b_n}\right\}$$

respectively. Then from the foregoing theorem it follows that the processes of addition, subtraction, multiplication and division may be carried out on regular sequences of rational numbers (with suitable restrictions in the case of division) and that the sequences which result from any finite number of applications of these operations are themselves regular sequences of rational numbers. Furthermore, it may be shown that the ordinary fundamental laws of algebra hold for operations with sequences, namely, the associative and commutative laws of addition and multiplication and the distributive law of multiplication (*q.q.v.*) with respect to addition. (See ALGEBRA.)

Since these regular sequences of rational numbers combine according to the same formal laws as rational numbers themselves, it is natural to take regular sequences of rational numbers as themselves defining a new sort of number; and this is what Cantor does. The new numbers are called *real numbers*. A rational number a may then be denoted by the sequence a, a, a, \dots each element of which is the rational number a . But this is not a unique representation of a . In fact, any sequence of rational numbers a_1, a_2, a_3, \dots having the rational limit a may be used to denote the number a . In general, the real numbers a and b defined by two regular sequences $\{a_n\}$ and $\{b_n\}$, respectively, are said to be equal

if for every positive rational number ϵ however small, a number n exists such that the numerical value of $a_{n+m} - b_{n+m}$ is less than ϵ for every positive integer m . The real number represented by $\{a_n\}$ is said to be of higher rank than the real number represented by $\{b_n\}$ if a value of n exists such that $a_{n+m} - b_{n+m}$ is numerically greater than some given positive number δ for all positive integers m . These definitions are sufficient to establish the relations of order among the real numbers.

The real numbers thus postulated satisfy the usual laws of algebra and possess an order relation analogous to that of rational numbers. In the domain of real numbers every regular sequence of rational numbers has a limit; namely, the real number defined by the sequence itself. The question naturally arises, whether every regular sequence of real numbers has a limit in the domain of real numbers. The answer is affirmative; that is, if definitions are introduced in connection with sequences of real numbers, in all respects analogous to those already given for sequences of rational numbers, then every regular sequence of real numbers has a limit in the domain of real numbers. Therefore regular sequences of real numbers lead to no further extension of the system of numbers. The fact that a regular sequence of real numbers always has a limit in the domain of real numbers renders the set of real numbers suitable to be the field of the real variable in a general theory of functions of real variables.

Any given simply infinite sequence a_1, a_2, a_3, \dots may be employed to define a new sequence s_1, s_2, s_3, \dots by writing

$$s_n = a_1 + a_2 + a_3 + \dots + a_n$$

The problems connected with the convergence of the sequence $\{s_n\}$ are then identical with the problems of the convergence of the infinite series

$$a_1 + a_2 + a_3 + \dots$$

Therefore a part of the theory of limits (see LIMIT) and the whole of the general theory of simply infinite series (see SERIES) are aspects of the theory of simply infinite number sequences. In a similar way the definition of a definite integral as the limit of a sum presents the theory of integration as another one of the fundamental applications of the theory of simply infinite sequences.

Other Types of Infinite Sequences.—A simply infinite sequence is said to be of type ω ; the distinguishing qualities of these sequences lie in their possessing a first term, a term following any given term but no last term, while the terms preceding any given term constitute a finite sequence. The symbol ω is used to denote what may be called a reversed simply infinite sequence. It has no first term but does have a last term, while every term but the last one is followed by a next term and all the terms following a given term constitute a finite sequence. A sequence of type ω is called an ascending sequence while one of type ω^* is called a descending sequence. As the positive integers 1, 2, 3, ... in order of magnitude form a typical ascending sequence so the negative integers in order of magnitude ..., -3, -2, -1 form a typical descending sequence. The sequence

$$\dots, -3, -2, -1, 0, 1, 2, 3, \dots$$

of positive and negative numbers and 0, taken in order of magnitude, form a sequence of type $\omega + \omega$, characterized by its possession of the following properties: there is no first term and no last term, there is a term next following any given term, and the elements following one and preceding another given element form a finite sequence.

In the development of the general theory of functions it has become necessary to consider many other types of sequences as well as order types of a more general character than those for which the term sequence is usually employed; on this account a general theory of sequences and order types has sprung up—usually developed both in treatises on functions of a real variable and in those on the theory of sets of points (see POINT SETS). A few of those usually called sequences may be briefly described. A sequence of type ω followed by another of type ω is said to form a sequence of type $\omega \cdot 2$. A typical instance is the following:

$$1, 3, 5, 7, \dots, 2, 4, 6, 8, \dots$$

If n such simple sequences are taken in a given order the resulting

sequence is said to be of type $\omega \cdot n$. A single sequence of type ω will then be noted by $\omega \cdot 1$. If any sequence of type $\omega \cdot n$ is followed by a finite sequence containing m elements, the sequence so formed is said to be of type $\omega \cdot n + m$.

Let S_1, S_2, S_3, \dots denote a simply infinite sequence each element of which is itself a simply infinite sequence. The sequence thus formed is said to be of type ω^2 . This process of forming sequences of sequences may be continued; it has given rise to a certain class of so-called transfinite numbers. The theory of these transfinite numbers, and of the sequences which underlie them, has been extensively developed; and it has given rise to important analyses of the logical processes involved in defining them and reasoning about them, processes usually investigated in the theory of sets of points, since these sequences may be represented to the mind by means of sets of points on a line.

Let us illustrate the last remark by exhibiting a set of points of type ω^2 . First define any simply infinite sequence of non-overlapping intervals on a given line, as, for instance, the intervals from 0 to 1, from 1 to $1\frac{1}{2}$, from $1\frac{1}{2}$ to $1\frac{3}{4}$, and so on without end, each interval after the first having half the length of the preceding one. On each of the intervals a set of points forming a sequence of type ω is to be defined. We might, for instance, define the points on a given interval I as follows. Let the first one be the midpoint P_1 of I , the second be the midpoint of the part of I to the right of P_1 and in general let the i th one P_i be the midpoint of the part of I to the right of P_{i-1} . Then on I we have a sequence P_1, P_2, P_3, \dots of points of type ω . When this is done for each interval I of the set of intervals and the resulting points are contemplated in their order from left to right on the line, we have a sequence of points of type ω^2 .

A typical arrangement of a sequence of type ω^2 is the following:

$$\begin{array}{ccccccc} a_{11}, & a_{12}, & a_{13}, & \dots, & & & \\ a_{21}, & a_{22}, & a_{23}, & \dots, & & & \\ a_{31}, & a_{32}, & a_{33}, & \dots, & & & \\ & \dots & \dots & \dots & \dots & \dots & \end{array}$$

the elements in each line forming a simply infinite sequence and the elements in any line preceding all the elements in each following line. Such a sequence is often called a *double sequence*. It is the type which underlies the general theory of double series. A fundamental problem concerning double sequences is that of the existence and equality of the limits

$$\lim_{m=\infty, n=\infty} a_{mn}, \quad \lim_{m=\infty} \lim_{n=\infty} a_{mn}, \quad \lim_{n=\infty} \lim_{m=\infty} a_{mn},$$

the last two denoting limits of limiting values while the first denotes the limit as m and n become infinite independently. If the first limit exists and is a then each of the other limits exists and is a . But one or both of the latter limits may exist while the first does not, nor is it necessary that the two latter limits (when they exist) shall be equal.

That the same set of objects may be contemplated in sequences of various types may be indicated by observing that the elements in a double sequence, or sequence of type ω^2 , are capable of an arrangement into a sequence of type ω . Thus, in the case of the foregoing array we may arrange the elements in the order of the finite diagonal sets and obtain the following sequence of type ω :

$$a_{11}, a_{12}, a_{21}, a_{13}, a_{22}, a_{31}, a_{14}, a_{23}, \dots$$

Recurrent Sequences of Integers.—In the theory of ordinary integral numbers certain simply infinite sequences of integers have been found to play an important rôle (*Quart. Journ. Math.*, 48 [1920]: 342–372). These integers satisfy recurrence relations of the form

$$u_{n+k} + \alpha_1 u_{n+k-1} + \dots + \alpha_k u_n = 0, \quad n = 0, 1, 2, \dots,$$

where $\alpha_1, \alpha_2, \dots, \alpha_k, u_0, u_1, \dots, u_{k-1}$ are given integers. If to take a simple case, the polynomial

$$\rho^k + \alpha_1 \rho^{k-1} + \dots + \alpha_k$$

is irreducible modulo p , where p is a prime, then the sequence of residues $\{r_n\}$, where $u_n \equiv r_n \pmod{p}$ and r_n is a number of the

set 0, 1, 2, $\dots, p-1$, is periodic and (when certain exceptional cases are removed) the period is a factor of $p^k - 1$. This theorem may be extended to the case of a general modulus m . In this connection several criteria have been obtained for recognizing certain large prime numbers as prime, the following being one of the simplest. A necessary and sufficient condition that $2^n - 1$ shall be a prime is that

$$(a + b\sqrt{-1})^{2^n} + (a - b\sqrt{-1})^{2^n}$$

shall be divisible by $2^n - 1$, where a and b are any integers such that $a^2 + b^2$ is a prime number of which $2^n - 1$ is a quadratic non-residue. By means of such theorems several large numbers have been shown to be prime, including the following:

$$2^{61} - 1, 2^{89} - 1, 2^{107} - 1, 2^{127} - 1, 5 \cdot 2^{75} + 1.$$

See E. W. Hobson, *Theory of Functions of a Real Variable*, vol. i. (3rd ed., 1927); and *Encyclopédie des Sciences Mathématiques*, tome i., vol. i. (R. D. CA.)

NUMENIUS, a Greek philosopher, of Apamea in Syria, Neo-Pythagorean and forerunner of the Neo-Platonists, flourished during the latter half of the 2nd century A.D. His chief divergence from Plato is the distinction between the "first god" and the "demiurge." This is probably due to the influence of the Valentinian Gnostics and the Jewish-Alexandrian philosophers (especially Philo and his theory of the Logos). His works were valued by the Neoplatonists, and it is said Amelius wrote about 100 books of commentaries upon them. Fragments of his treatises on the points of divergence between the Academicians and Plato, on the Good (in which according to Origen, *Contra Celsum*, iv. 51, he makes allusion to Christ), and on the mystical sayings in Plato, are preserved in the *Præparatio Evangelica* of Eusebius.

The fragments are collected in F. G. Mullach, *Frag. phil. Graec.* iii.; see also F. Thedinga, *De Numenio philosopho Platónico* (Bonn, 1875); Ritter and Preller, *Hist. Phil. Graecae* (ed. E. Wellmann, 1898), T. Whittaker, *The Neo-Platonists* (1901; 2nd ed. 1918) and Überweg, *Grundriss der Gesch. der Philosophie* Bd. I. (1926).

NUMERALS. Just as the first attempts at writing came long after the development of speech, so the first efforts at the graphical representation of numbers came long after people had learned to count. Judging by the habits of primitive tribes of the present as well as by the oldest trace that we have of written or sculptured records, the earliest numerals were simple notches in a stick, scratches on a stone, marks on a piece of pottery, or the like. Having no fixed units of measure, no coins, no commerce beyond the rudest barter, no system of taxation, and no needs beyond those of a savage, there was no necessity for written numerals until about the beginning of what we call historical times.

Early Forms.—The earliest numerals of which we have definite record were simply straight marks for the small numbers, with some special form for ten. These symbols appear in Egypt as early as the 1st dynasty (c. 3400 B.C.), and in Mesopotamia as early as c. 3000 B.C. These dates long precede the first known inscriptions containing numerals in India (c. 3rd century B.C.), in China (3rd century B.C.), and in Crete (c. 1200 B.C.).

Egyptian hieroglyphic, c. 3400 B.C.	10
Egyptian hieratic, c. 3400 B.C.	18
Cretan inscriptions, c. 1200 B.C.	17
Sumerian and later, c. 3000 B.C.	74

Somewhat later it is not uncommon to find a group mark before 10 is reached. For example, four has a special symbol in certain Hindu types, as here shown:

Asoka's time, 3rd century B.C.	41
Nānā Ghāt, 2nd century B.C.	41
Saka, c. 1st century B.C.	41

Nasik, 1st or 2nd century 大 一
Kuşana, c. 150 + 1

Early Hindu Symbols for 1 and 4.—Even to-day a Chinese merchant may write one and four in the forms 1 and X respectively, instead of using the classical symbol. This use of a symbol for four may, in fact, have preceded the Western habit of taking

THE DEVELOPMENT OF NUMERALS THROUGH THE SYMBOLIC, DECIMAL AND CIPHER STAGES

ten as the first group number, and the Etruscan and Roman use of V or Λ for five may have been a hand symbol in use before the X was taken for ten.

The vertical marks, I, II, III, etc., may possibly be representations of the fingers held as used in counting and computing, a linguistic trace of which is found in the word *digit*. The horizontal marks may be representations of computing rods as they lie on a table. The vertical symbols were preferred in Mesopotamia and the Mediterranean region, and the horizontal ones in the Far East, where 一, 二, and 三 were commonly used for one, two, and three, 二 and 三 being cursively written to give us our present 2 and 3.

It therefore appears that the primitive numerals were I, II, III, IIII, and so on, as we find in Egypt and the Grecian lands, or 一, 二, 三, and probably so on as we usually find in the East, each going as far as the simple needs of people required. The idea of a group figure would naturally have occurred to merchants as soon as there developed a need for numbers beyond 10 or 12 (as was the case in Egypt and Babylon). Once the idea was suggested, probably influenced by the ten fingers, symbols were invented for smaller units, as in the case of those used for four and five as stated above. These naturally suggested special symbols for each of the numbers from one to ten or even farther, and the use of the additive principle to build up larger numbers, as in the Roman XXII. The idea of special symbols for larger groups, as for 20, 30, and so on, was a natural extension.

Cuneiform Numerals.—Around Babylon, clay was abundant; and in the damp clay tablets they impressed their symbols, then baking these tablets in the sun or in a kiln, thus forming historical documents that were practically as permanent as stone. Since the pressure of the stylus gave a wedge-shaped symbol, the writings are known as cuneiform (Lat. *cuneus*, a wedge, + *forma*, a shape) inscriptions.

For our purposes some leading principles will suffice. The symbol for 1 served also for 60, 3,600, and in general for 1×60ⁿ; similarly the symbol for 10 served for 10×60ⁿ, the context telling

what particular value was indicated. The symbols could be made either with the pointed or the circular end of the stylus, as follows:

V or 1 one < or ● ten

There was also a symbol for 100, but in general the scribe preferred to make use of the symbol for 60, thus:

$$V \triangleright = 100 \quad V \triangleright V \triangleright V \triangleright V \triangleright = 60 + 60 + 10 + 10 + 10 + 10 + 10 + 10 + 10 + 10 = 171\frac{1}{2}$$

$$)) \odot \odot = 60 + 60 + 10 + 10 = 130\frac{1}{2}$$

Following the general custom of the race to use small numbers instead of large ones, the Babylonians employed a subtractive principle, as we do in saying "a quarter to three" instead of "three quarters past two," and "three minutes to six" instead of "57 minutes after five." This appears in such numerals as

$$< < < \triangleright 10 + 10 - 1 = 19, \quad \text{and} \quad \odot \odot \odot \odot \odot = 20 - 3 = 17.$$

A similar custom is seen in Hebrew number names, in the occasional use of IV. for four and IX. for nine in the Roman inscriptions. The Romans also used *unus de viginti* for 19, and *duo de viginti* for 18, occasionally writing these numbers as XIX. (or IXX.) and IXXX., respectively. On the whole, however, the subtractive principle was little used in the numerals of the classical period.

Egyptian Hieroglyphics.

The Egyptian numerals in hieroglyphic writing differed somewhat from those in the hieratic and demotic, but the last two were degenerate forms of the first, with certain additions. It will suffice to call attention to the principles of the first and second. In doing so, however, it should be observed that the Egyptians generally wrote from right to left, as in the Semitic script, but the hieroglyphics were occasionally written from left to right or (as also the Hieratic) from top to bottom. The numerals from 1 to 10 were as follows:

Hieroglyphic I II III IIII IIII IIII IIII IIII IIII IIII
Hieratic I II III IIII IIII IIII IIII IIII IIII IIII

The hieroglyphic symbols for certain larger numbers were as follows:

10 11 12 20 40 70 100 200 1000 10,000

It will therefore be seen that the general plan of the hieroglyphic notation was to have special symbols for powers of 10, and to repeat these as necessary. The Hieratic had special symbols for 5, 7, 8, and 9—a step towards the later Hindu system. The Hieroglyphic was similar in principle to the Etrusco-Roman, except that the latter introduced special numerals for 5, 50, and 500.

Greek Numerals.

The Greeks had two important systems of numerals, besides the primitive plan of repeating single strokes, as in III III for six. Their predecessors in culture—the Babylonians, Egyptians, and Phoenicians—had generally repeated the units up to nine, with a special symbol for ten, and so on. The early Greeks also repeated the units to nine, and probably had various symbols for ten. In Crete, whose early civilization was so much influenced by that of Phoenicia and Egypt, the symbol for ten was 一, a circle was used for 100, and a rhombus for 1,000. Cyprus also used the horizontal bar for ten, but the precise forms

FROM SMITH, "HISTORY OF MATHEMATICS"
FIFTEENTH CENTURY FINGER SYM.

BOLISM
From *Soma* of Paololi, Venice, 1494

are not of so much significance as that the grouping by tens, with special symbols for certain powers of ten, was characteristic of the early systems of the Near East.

The Greeks, entering the field much later, and influenced as to their alphabet by the Phoenicians, based their first elaborate system chiefly on the initial letters of the numeral names. This was a natural thing for all early civilizations, since the custom of writing out the names for large numbers was at first quite general, and the use of an initial by way of abbreviation of a word is universal. These initial numerals, in modern characters, were

Π, *pi*, for ΠΕΝΤΕ (*pente*), five;

Δ, *delta*, for ΔΕΚΑ (*deka*), ten; often written like Ο;

Η, an old Attic breathing, like our *h*, later represented by a special symbol like χ , for ΗΕΚΑΤΟΝ (*hekatón*), hundred;

Χ, *chi*, for ΧΙΛΙΑΙ (*chi'ioi*), thousand;

Μ, *mu*, for ΜΤΡΙΑΙ (*myr'ioi*, *mur'ioi*), ten thousand.

These numerals were frequently combined, thus:

ΠΔ or ΠΔ, *pente-deka*, for 5×10 , or 50;

ΠΑ, *pente-hekaton*, for 5×100 , or 500;

ΠΜ, *pente-murioi*, for $5 \times 10,000$ or 50,000.

This system appears in records of the 3rd century B.C. but was probably used much earlier. In the 2nd century of our era it was described by the grammarian Herodianus, and hence characters are often spoken of as Herodianic numerals. They are more properly called Attic numerals, being the ones always found in the Attic inscriptions.

As early as the 3rd century B.C. another system came into use, running parallel to the initial-letter one, being better adapted to the theory of numbers, and being more difficult of comprehension by the trading class. It consisted in assigning nine letters of the alphabet to the numbers 1-9, nine letters to the numbers 10, 20, 30, ..., 90, and nine letters to the numbers 100, 200, 300, ..., 900. Since, however, there were only 24 letters in the Greek alphabet, three were added, namely the Phoenician *vau* (shaped like our letter F), *koph* or *qoph* (shaped somewhat like our letter Q, which indeed is derived from the same source, and represented below as Q), and a character known in modern times as *sampi* (and then shaped somewhat like the Greek π, but tipped about 45° to the right and represented below as &). An earlier form of this last symbol was &. The numerical values of the letters were therefore as follows:

Units	Α	Β	Γ	Δ	Ε	[F]	Ζ	Η	Θ
	1	2	3	4	5	6	7	8	9
Tens	Ι	Κ	Λ	Μ	Ν	Ξ	Ο	Π	[Q]
	10	20	30	40	50	60	70	80	90
Hundreds	Ρ	Σ	Τ	Υ	Φ	Χ	Ψ	Ω	[&]
	100	200	300	400	500	600	700	800	900

The thousands were often indicated by placing a bar to the left of the numeral, thus:

$$\overline{Α} = 1,000 \quad \overline{Β} = 2,000 \quad \overline{Ι} = 10,000 \quad \overline{Σ} = 200,000$$

The myriads (ΜΤΡΙΑΙ, *myrioi*, ten thousands) were represented by such symbols as

$$\overline{\overline{Τ}} \text{ or } \overline{\overline{Μ}}, \text{ for } 10,000, \quad \overline{\overline{Δ}} \text{ for } 4 \times 10,000, \text{ or } 40,000, \text{ etc.}$$

Such numeral forms were not particularly difficult for computing purposes, once the operator was able automatically to recall the meaning of each. To be able to express 10,407 by ΜΤΖ would have seemed to a Greek considerably simpler than by our system. The capital letters were used by the Greeks, the small letters being a relatively modern invention.

Hebrew Numerals.—By the 2nd century B.C. at the latest, the Hebrews had established a system of alphabetic numerals similar to the one used by the Greeks. The alphabet being exhausted when the symbol for 400 was reached, the letters for 400 and 100 were combined by early writers to represent 500, and similarly up to 900. Later scholars used the final forms of the letters for 20, 40, 50, 80 and 90 (that is, the form of the letter that would

be used at the end of a word) to represent 500, 600, ..., 900. The scheme then appeared as follows:

Units	א	ב	ג	ד	ה	ו	ז	ח	ט
	1	2	3	4	5	6	7	8	9
Tens	י	כ	ל	מ	נ	ס	ע	פ	צ
	10	20	30	40	50	60	70	80	90
Hundreds	ק	ר	ש	ת	ך	ם	ן	ף	ץ
	100	200	300	400	500	600	700	800	900

Roman Numerals.—The direct influence of Rome for such a long period, the superiority of her numeral system over any other

simple one that had been known in Europe before about the 10th century, and the compelling force of tradition explain the strong position that the system maintained for nearly 2,000 years in commerce, in scientific and theological literature, and in *belles lettres*. It had the great advantage that, for the mass of users, the memorizing of the values of only four letters was necessary—V, X, L, and C. Moreover, it was easier to see three in III than

FROM SMITH, "HISTORY OF MATHEMATICS"
SIXTEENTH CENTURY FINGER SYMBOLISM

From the *Abacus* of Johannes Aventinus, Nürnberg, 1522

in 3, and to see nine in VIII than in 9, and correspondingly easier to add numbers—the simplest of all the operations.

As in all such matters, the origin of these numerals is obscure, although the changes in their forms since the 3rd century B.C. are well known. Of the various theories that of Mommsen (1850) has had the widest acceptance. This was that the use of V for 5 is due to the fact that it is a kind of hieroglyphic representing the open hand with its five fingers. Two of these gave the X for ten. Three of the other symbols, he asserted, were modifications of Greek letters not needed in the Etruscan and early Latin alphabet. These were *chi*, which appears in inscriptions not only as X but also in such forms as ⊥, †, and which later became the L that was arbitrarily chosen for 50; *theta*, Θ, which was selected for 100, being finally changed to C under the influence of the word *centum* (hundred); and *phi*, Φ, to which was assigned the value 1,000, and which finally took the forms (I), and M, the last being chosen because of the word *mille* (thousand). There is considerable epigraphical evidence in support of these contentions made by Mommsen. (See the bibliography for other theories.)

The oldest noteworthy inscription containing numerals representing very large numbers is on the *columna rostrata*, a monument erected in the Roman forum to commemorate the victory of 260 B.C. over the Carthaginians. In this a symbol for 100,000, which was an early form of ((I)), was repeated 23 times, making 2,300,000. This illustrates not only the early Roman use of repeated symbols, but also a custom which extended to modern times—that of using (I) for 1,000, ((I)) for 10,000, (((I))) for 100,000, and (((((I)))) for 1,000,000. The symbol (I) for 1,000 frequently appears in various other forms, including the cursive ∞. All these symbols persisted until long after printing became common. In the middle ages a bar (*vinculum*, *titulus*) was placed over a number to multiply it by 1,000, but this use is not found in the Roman inscriptions. When the bar appears in early manuscripts it was merely for the purpose of distinguishing numerals from nouns, as in the case II VIR for *duumviri*. We also find in the middle ages such forms as [X] or [XI] for ten hundred thousand and [M] for one thousand hundred thousand.

Of the later use of the numerals, a few of the special types are as follows:

- (1) $\overline{c} \cdot \overline{lxiii} \cdot ccc \cdot l \cdot i$, for 164,351, Adelard of Bath (c. 1120).
- (2) II DCC. XIII, for 2,814, Jordanus Nemorarius (c. 1125).
- (3) MDCLVI, for 1,656, in San Marco, Venice.
- (4) oIo. Io. Io., for 1,599, Leyden ed. of Capella, 1599.
- (5) IIIIxxet huit, for 88, a Paris treaty of 1388.
- (6) four CII.M, for 451,000, Baker's arithmetic (1568).
- (7) vj.C for 600 and CCC.M for 3,000, Recorde (c. 1542).

Modern Arabic . . . 1 2 3 4 5 6 7 8 9 .

The first definite external reference to the Hindu numerals is in a note by Severus Sebokht, a bishop who lived in Mesopotamia c. 650. Since he speaks of "nine signs," the zero seems not to have been known to him. By the close of the 8th century, however, some astronomical tables of India are said to have been translated into Arabic at Baghdad, and in any case the numerals became known to Arabic scholars about this time. About 825 al-Khwarizmi (*q.v.*) wrote a small book upon the subject, and this was translated into Latin by Adelard of Bath (c. 1120) under the title of *Liber Algorismi de numero Indorum*. There is some reason for believing that the numerals found their way into Europe even earlier than into Baghdad, but the earliest European

manuscript that is known to contain them was written in Spain in 976. The table on preceding page shows their subsequent development until the time of printing.

NUMERAL SYSTEMS. There is no language without some numerals; the notion of unity and plurality is expressed at least in the formation of "one" and "two," though "two" is often equal to "much," thus concluding a numeration that has just only started. It is doubtful whether even systemless numeration really exists, as it is mostly reported of peoples who are but vaguely known. The eastern languages of Australia, in spite of the occurrence of numerals for "three" and even "four," and in a less degree the western languages, Yuin-Kuri, Wiradhuri, Kamilaroi, and the southern central languages have been suspected of it. It remains doubtful whether Tasmania practised systemless or pair numeration. The Pygmies of the Andaman islands and Malacca form numerals for "one" and "two," yet sum up only with units, not with pairs. So with the Chiquito in South America.

The Pair System.—The pair system has numerals for "one" and "two" and forms the following numerals by addition to the "pair": $3=2+1$, $4=2+2$, $5=2+2+1$, etc. It is found in Australia among tribes ethnologically the oldest—the Kulin-Kurnai of the south-east, the Narrinyeri of the south; several of them count up to "ten" in this manner. A pure pair system still occurs in many Papuan languages of Torres straits and the adjacent coast of New Guinea. In Africa it is practised by the Bushmen. In South America it is found among the ethnologically oldest tribes—the Fuegian tribes: Yamana and Halakwulup, the Guayaki and Shipaya, and the Ges-Tapuya tribes.

The pair system starts from the parts of the human body that exist in pairs, like eyes, ears, hands, feet. The pair system is also found in various associations with later numeration systems. The formation of a dual with the personal pronoun (and substantive) can be traced back to those times.

The Quaternary System.—The quaternary system forms the numerals above "four" by composition: $5=4+1$, $7=4+3$, $8=4+4$ (or 2×4), $9=(2\times 4)+1$, $16=4\times 4$. In this consequent type, however, it is but seldom met, e.g., in California with the Salina and traces of it with the Chumash. In California the four quarters of the sky play an important part in religion, mythology and custom.

The Hexad System (Senary System).—When further developed to a duodecimal system this is the most useful of all as it permits of more divisions without fractional numbers than any other system, and in later stages it has been repeatedly introduced especially for astronomy or in metrical or monetary systems. In primitive numeration it has a rather limited dispersion in north-west Africa, e.g., in the Huka, the Bulanda, the Apko; traces of it are to be met with among the Bube on Fernando Po.

The Quinary System.—The quinary system in its pure form, where for instance $10=2$ hands, $25=5$ hands, is found only in Saraweka, a South American Arowak language. Everywhere else it is combined either with the decimal or the vigesimal system.

The Vigesimal System.—The vigesimal system takes 20 as a basis, so as to make 20×20 the numeral next in height, if the numeration goes as far as that. It may combine either with the quinary system forming a quinary vigesimal system or more rarely and only in younger forms with the decimal system, and then becomes a decimal vigesimal system. The quinary vigesimal system is frequently combined with the pair system, so that the numbers 3 and 4, often also 6, 7, 8, 9, and further 12 and 13, are formed according to the pair system.

These systems start with the fingers and the toes. Therefore "five" often means "hand," "ten" means "the two hands," 11 "one at the foot," 20 "both the feet (and hands)" or "the whole man."

The quinary vigesimal system is found sporadically in almost all the Australian linguistic groups; in nearly all the Papuan languages of the (north) east coast and exterior of New Guinea, in the oldest Melanesian languages of New Caledonia, the Loyalty islands, etc. In Asia-Europe it occurs in the border languages: Ainu, Chukchi, Koryak, in Burushaski (*q.v.*), and in the Himalaya group of the Tibeto-Burman languages.

The decimal vigesimal system is found in the Munda languages of India and in Tibeto-Chinese groups of the Himalayas, in Nicobarese, in the north (and south) Caucasian languages. With the Indo-European and the Semitic languages the dual form for 20 seems to point to a former vigesimal system. The Sumerian, too, shows traces of it. Basque practises a full (decimal) vigesimal system, so that forms like *soixante-dix*, *quatre-vingt*, *quatre-vingt-dix* in French are to be explained.

In Africa the vigesimal system occurs in upper Guinea, and its hinterland, from the Senegal to the Cross river, in a series of Bantu, Mande, Togo and Niger languages, and in some east Bantu languages, in the Hamitic Kunama (and Barea) and in the Bantu languages Konde and Sango.

In North America it is found in Eskimo and in the north-west in Bellacoola and Haida and several languages of California, together with Pawnee (Caddo). This system mostly as decimal vigesimal is dominant in Mexico, Central America, even in the languages of the high civilization of the Aztecs and Maya. In South America the vigesimal system is found both in the progressive civilization of the Chibchas and with a great many primitive tribes belonging to nearly every linguistic group save the Gez-Tapuya and the tribes south of the Gran Chaco.

The quinary vigesimal system, especially its older form combined with the pair system, appears to have originated in the culture cycle (*Kulturkreis*, culture area) of the totemistic-patriarchal progressive hunters; a culture type in which the human body in art (sculpture), clothing and adornment has gained greatest importance and is most cared for. According to that the vigesimal system, too, agrees up to 20 with the parts of the body.

In north-western Africa on the coast of upper Guinea a quadragesimal system has developed, derived from a vigesimal system. Its origin is due to commercial reasons, as the monetary standard in this region is a set of 40 cowries.

The Decimal Systems.—The decimal systems are superior to the vigesimal systems in taking as a basis a smaller numeric unity more easily applied, and render possible shorter forms of the numbers. Two forms are known, the quinary decimal system and the pure decimal system. In the quinary decimal system the numbers of the second pentad are formed by composition with "five" ($6=5+1$, $7=5+2$, etc.) or by the pair system (especially $6=3\times 2$, $8=4\times 2$) or by subtraction (especially $9=10-1$). It seems to have originated in the matriarchal soil-tilling culture. The great quantity of agricultural products which had to be counted, arranged, stored, and brought to market required to be frequently repeated and counted quickly, and thus led to this system. In the languages of this culture numeral unities have developed which spring from the special grouping of certain products: a dozen, a brace, score (three score), etc.

In Australia and in the Papuan languages it is found isolated and in rudimentary form; with the Melanesians it is fully displayed. In Asia it originally dominated the two great families of the Austroasiatic and the Tibeto-Chinese languages. Whether a quinary or a pure decimal system was the original numeration in the Ural-Altaic languages cannot be ascertained. In Africa the great majority of the languages show originally a quinary decimal system, especially the Bantu and the semi-Bantu languages and the majority of the Nilotic, Wule, Ngo-Nke and Manfu languages. So too, in North America; but neither in Mexico, Central America, nor in South America has the system spread widely.

With the pure decimal system there is no partition of the decad into two pentads and therefore the compound character of the numerals from five to ten is not met with. The whole system

becomes simpler and its forms are better fitted for general application. The pure decimal system seems to have originated in the culture-cycle of the nomadic herders, who, in counting their large flocks of horses, cows, camels, sheep, etc., needed to employ high numbers with more facility. From the aristocracies of the nomadic herders it has spread everywhere, and it is now found in all nations of high culture on the whole globe, except those of Mexico and Central America, where the number 20 was used in astronomy, and thus was safe from competition. (P. W. S.)

NUMERATION: see NUMERALS; ARITHMETIC.

NUMIDIA, the classical name of a territory in the northern part of Africa. When the Romans first came into conflict with Carthage in the 3rd century B.C., the name was applied to the whole country from the river Mulucha (now the Muluya), to the frontier of the Carthaginian territory. Numidians were divided into two great tribes, the Massyli on the east, and the Massaesyli on the west, the limit between the two being the river Ampsaga. At the time of the second Punic war, the eastern tribe was governed by Massinissa, who took the side of the Romans, while Syphax, king of the Massaesyli, led the Carthaginians. At the end of the war, the Romans confiscated the dominions of Syphax, and gave them to Massinissa, whose sway extended from the frontier of Mauretania to the boundary of the Carthaginian territory, also south and east to the Cyrenaica, so that the Numidian kingdom surrounded Carthage except towards the sea. Massinissa, who reached a great age, retained the whole of these dominions till his death in 148 B.C. and was succeeded in them by his son Micipsa, who died in 118. For the war with Rome which followed the death of Micipsa, see JUGURTHA.

After the death of Jugurtha, the western part of his dominions was added to those of Bocchus, king of Mauretania, while the remainder continued to be governed by native princes until the civil war between Caesar and Pompey, in which Juba I. was defeated by Caesar. Numidia in the more restricted sense became for a short time a Roman province under the title of Africa Nova, but after the battle of Actium it was restored to Juba II., who had acquired the favour of Augustus. In 25 B.C., Juba was transferred to the throne of Mauretania, including the whole western portion of the ancient Numidian monarchy as far as the river Ampsaga, while Africa Nova was rejoined to the province of Africa; together with Africa Vetus it was governed by a proconsul, and was the only senatorial province in which a legion was permanently stationed. In A.D. 37 the Emperor Gaius sent a legatus of his own to take over the command of the legion (see AFRICA, ROMAN). Under Septimius Severus (A.D. 193-211) Numidia was separated from Africa Vetus and governed by an imperial procurator (*procurator per Numidiam*); finally, under Diocletian, Numidia became one of the seven provinces of the diocese of Africa, being known as Numidia Cirtensis, and after Constantine as Numidia Constantina. During this period it reached a high degree of civilization, and was studded with numerous towns, the importance of which is attested by inscriptions and by the massive remains of public buildings. The invasion of the Vandals in A.D. 428 reduced it to a condition of decay; and the invasion of the Arabs in the 8th century again brought desolation on the land, which was aggravated by misgovernment till the conquest of Algeria by the French in 1833.

Chief towns of Numidia under the Romans were: in the north, Cirta, the capital, which still retains the name Constantine given by Constantine, and Hippo Regius, the see of St. Augustine; to the south, Theveste (Tebessa) and Lambaesis (Lambessa), connected by military roads with Cirta and Hippo respectively. Lambaesis was the seat of the legion III. Augusta, and the most important strategic centre.

For bibliography and account of Roman remains, see AFRICA, ROMAN.

NUMIDINAE: see GUINEA-FOWL.

NUMISMATICS (from the Latin *numisma*, a coin) is the study of coins and medals. Coins were first issued in east and west in the eighth century B.C., and since then their use has spread over the whole civilised world. Unlike many objects in every-day use, they have always been highly prized by their

owners, and were therefore frequently hoarded. As is still the custom in the east, it was usual to bury treasure for safety, with the result that the contents of such ancient and mediaeval savings banks are frequently turned up by the spade to-day. Coins are themselves the most imperishable of antiquities. The result is that they still exist in vast numbers of forgotten generations out of all proportion to other remains of the culture with which they were contemporary. The study of coins may therefore be expected to yield a considerable amount of information about the past, although we must be careful not to exaggerate their importance. Coins give us some idea of the wealth and importance of ancient states and cities. A study of the find-spots of coins gives an idea of their circulation in ancient times, and it is sometimes possible to make deductions about the extent of the dominion of a particular state from this; chronological analyses of finds, by reasoning from known dates to pieces of which the dates are hitherto unknown, has often given valuable results. The argument from find-spots has to be used with care, as commercial reasons frequently explain the finding of coins far from their original mints. Thus, the frequent finds of Roman gold of the early empire in India do not show that the Romans ruled there, but corroborate Pliny's reference to the tremendous drain on Rome for gold to pay for Indian luxuries; to go to the other end of the world, the huge finds of Arab silver coins in Scandinavia were brought there to pay for furs for the wealthy Abbasids and Samanids. At all times certain currencies have acquired especial popularity and have wandered far; such were in ancient times the tetradrachms of Athens and the staters of Philip II.; in mediaeval times, the dinars of the early caliphs and the ducats of Venice, and in modern times the Mexican and Maria Theresa dollar and the English sovereign.

Commercial and economic history can thus learn much from coins; their depreciation reveals times of economic stress; the base Roman antoniniani of the third century tell their tale as readily as the inflated paper currency of Germany in 1919. The imitation of the Edward I. penny on the Continent shows how welcome a really good coin was in those days of base deniers.

Coins and medals have preserved a series of portraits which throw light on the characters of their issuers. Of particular value is the light thrown by coins on ancient religion and mythology.

As datable objects they are above all valuable as the grammar of art. Not only do they throw light on local forgotten schools and preserve representations of long-lost masterpieces, but it is from them that the chronology of ancient art has been fixed. A long series of coins of a Greek town, ranging from the archaic period to the decline of art, sets a standard of comparison which enables sculpture and other objects to be dated.

The principal metals in which coins are struck are electrum, gold, silver, copper and bronze.

Electrum is a natural mixture of gold and silver which was used for the earliest Greek coins struck in Asia Minor (Lydia) until Croesus replaced it by pure gold. Electrum was the metal of the great 5th century coinage of Cyzicus. An artificial electrum was used in the 5th and 4th centuries in Carthage and Sicily.

Gold was the great currency of Asia, of the later Lydian kings, of the Achaemenids, of the Kushans and most Indian dynasties till the 12th, and again in the 17th century. In Europe it is not found till the great coinages of Philip II., Alexander III. and Lysimachus of Macedon; in Europe we find it in the Roman and Byzantine empires and their successors till the 8th century; it was revived in the 12th century with the great commercial currencies of the Italian republics and from the middle of the 14th century became the standard of the northern countries of Europe also.

In the ancient world silver was the currency of early Greece and of Republican Rome, and of the 9th to the 14th century in Europe generally; it was the currency of the Parthians, and on the whole of the Sassanians, and of the Asiatic state of the middle ages.

Bronze or copper was the early currency of Rome and Northern Italy and of China till modern times: it first appears in Greece towards the end of the fifth century, and here as usual in its later numismatic history throughout the world was used only for small change.

Lead has only been occasionally used for coins; the only lead currencies of any note are that of the Andhras of ancient India and the modern coinages of the Malay States. Iron was occasionally used in the ancient world and during the World War in Germany. Nickel was used in Bactria, 3rd century B.C., and has been extensively used in modern currencies since the middle of the nineteenth century. The only pre-war aluminium coinage was that for British East Africa in 1908, but it was not a success. Aluminium and aluminium-bronze have recently been used for a number of the post-war currencies of modern Europe.

GREEK COINS

A coin may be defined as a piece of precious metal stamped with some mark or type or inscription showing that it is issued by some authority which guarantees its weight and purity. Coins as we know them are not older than the 8th century B.C. Traces of more primitive currencies which preceded them survived into historic times. Passing over the stage of barter, when a superfluity of one necessity of life was exchanged by its owner for another necessity of which he was in want but could not so easily supply, we find that certain things, notably oxen and instruments of husbandry, early became standards of value and were used as mediums of exchange. Among the Romans for example we find fines exacted in cattle down to the end of the 5th century B.C. and the etymology of *pecunia* from *pecus* shows that coined money took the place of cattle. With the passing of a pastoral civilization and the transition to an agricultural community with its multiplicity of products a demand for some more convenient medium and for small change was felt. We have abundant evidence of the use of agricultural implements and household utensils as currency in the ancient world. In China for example the earliest coins of the 8th century B.C. are models of the spades and bill-hooks which preceded them, with the addition of a proper coin-inscription showing they were issued by authority. In pre-historic Europe we have in Gaul hoards of small bronze celts which seem to have been used for currency. The most certain survival of this coin in the Mediterranean world is the iron or bronze spit (*obeliskos*—whence the name *obol* for a small coin); hoards of these spits have actually been found in circumstances which show that they were currency; the most remarkable of these hoards of spits is that found in the Heraeum in Argos, dedicated by Pheidon himself—whether as specimens of demonetised currency or as standards set up in connection with Pheidon's reforms or simply dedicated specimens of the usual currency is disputed; similar bundles of spits in bronze and iron have been found in Etruria. In Homer we find basins, tripods and axes used as gifts and prizes in a way which shows that they were a recognised standard of wealth. With the invention of the scales these more or less clumsy currencies disappeared and we have the metal itself used; a definite weight takes the place of a particular shape. In all countries from the 10th to the 5th centuries B.C. we find hoards of broken bronze or silver, sometimes shapeless, sometimes cast in the form of bricks or plates; later it is regularly in the form of bars which could be broken and weighed. We have finds of silver of this kind from Assyria of the 8th century B.C. and from Egypt and South Italy of a little later. The Egyptian finds frequently contain Greek silver coins chopped in a way which shows they were considered only as bullion. In Italy in particular rude chunks of copper (*aes rude*) were regular currency from early times to the 3rd century B.C. as we know from literary references and from finds. Caesar tells us that the ancient Britons used iron bars of a definite weight and specimens still survive; excavations have also confirmed the accuracy of Plutarch's reference to the iron money of the Spartans.

The large oblong Roman bronze pieces with a type on either side form a kind of transition from metal bars to coins although they are not earlier than some Roman coins—in any case it is a short step from the use of metal by weight to its use in pieces of definite weights with a stamp of some kind guaranteeing it is what it professes to be, so that it can be paid without weighing; at this stage it becomes a coin; it is in this form that coinage first meets us in Greece and India.

Period I. 750–480 B.C.—Ancient tradition—Xenophanes in the 6th and Herodotus in the 5th century—ascribes the invention of coinage to the Lydians; the latter says they were the first to strike coins of gold and silver. This definite statement probably refers to a period after the beginnings of coinage when Croesus of Lydia struck coins of pure gold and pure silver. We have, however, evidence of an earlier coinage of Lydia and Ionia of electrum, a natural mixture of gold and silver, the "white" gold of the Greeks; these early pieces, as the finds at Ephesus show, belong to the 8th century B.C. (Pl. I.1). They are little globules with a variety of stamps which suggests that they are private issues and not issues of a state authority; this early coinage is irregular in weight and quality and unsystematic in character and it is not till the issues of Croesus that we have in Asia Minor an undoubted coinage by a state authority. The types on his gold and silver coins are the same, the heads of lion and bull facing one another and reverse a double incuse square caused by the anvil in striking (Pl. I.3).

In contrast to this early electrum coinage, irregular, alike in quality, types and shape, is the almost contemporary earliest coinage of Greece proper, even the oldest specimens of which, unlike the electrum, are at once recognisable as coins to the least trained eye. This is of silver and capable of definite attribution. The oldest are those of Aegina and if the not early but persistent ancient tradition which says that coinage was invented by Pheidon king of Argos is correct, these would be his coins. The type of Aegina is a turtle—an animal associated with Aphrodite—on the obverse, an incuse square on the reverse. That the coins of Aegina are the earliest is supported by the fact that the Aeginetic standard is the commonest on the earlier coins of the islands, the Peloponnese and Greece proper; it was later supplanted by the Euboic-Attic standard, the adoption of which by Solon for Athens led to its wide dissemination. By the end of the 6th century the practice of striking coins was well established in many centres. Corinth with its *pegasi* (Pl. I.9)—from their type of a pegasus—struck staters on its own standard, a variant of the Attic and began to strike not long after Aegina; it is not improbable that Periander was the institutor of the Corinthian coinage which became one of the great commercial currencies of the Greek world. The date of origin of the coinage of Athens is still uncertain; the well known types of the head of Athena on the obverse and her attribute the owl on the reverse date from the middle 6th century and are the earliest coins with a type on both sides and the earliest to bear a human head (Pl. I.8). The exact attribution to Athens of its Solonian and pre-Solonian coins is still disputed. By the institution the "owls," a type of coin, obv. deity and reverse an attribute of the deity, was developed which had a far-reaching effect on the development of coin-types; the head of the king on an English penny goes back to the head of Athena through the deified head of Alexander and the Britannia on the reverse similarly can be traced back to the owl. Other important towns like Thebes and trading centres like Corcyra began to issue coins about this time but a number of important towns seem to have still been content to use the currency of their neighbours. In the 6th century also we have the earliest coins of Africa in the issues of the Spartan colony of Cyrene with its badge the silphium plant, the cultivation of which was its great source of revenue. Coinage was also begun by the Greek colonies in South Italy and Sicily; these latter are of a characteristic fabric. Instead of the thick dumpy piece with a type on the obverse only and an incuse square on the reverse which are common to the cities and islands of Greece, we have broad thin pieces with the type struck on both sides, in relief on the obverse, incuse on the reverse (Pl. I.5). We possess many coins of this type of Tarentum, Metapontum, Croton, Rhegium, Zankle (Messana), etc. By the time of the Persian Wars coinage was a familiar feature of everyday life in the cities of the Greek world. Traders and colonists had carried the art to Cyrene in North Africa from Sparta to south Italy from Corinth, and to Sicily from Athens and the Peloponnese. In Asia Minor also coinage spread southwards and had reached Cyprus but not yet Crete. The Phoenicians and Egyptians were already familiar with Greek coins but did not

attempt to copy the invention; in the north however the silver mints of Thrace and Macedon were beginning to be worked vigorously and not only the Greek cities but the barbarian tribes, also, who employed Greek legends on their coins, were actively striking.

The various coinages of this early period (down to 480 B.C.) have a number of features in common. One of the most remarkable to the modern eye is the absence of inscriptions; these are either non-existent or consist only of the initial letter or letters of the town issuing the coin. The device of the town was originally sufficient for local circulation but as coins began to go further afield it became necessary to add some indication of its name. The earliest coin legends are therefore very brief: a *koppa* for the initial of Corinth, a Φ (*phi*) for Phocaea, Σ Γ (*Sig*) for Sybaris, $\text{A}\Theta\text{E}$ for Athens, and so on. The earliest inscriptions of any length are still written from right to left. Long inscriptions like "I am the badge of Phanes" above a stag on an archaic coin of Ephesus or "the stamp of Gortyna" on an early coin of the Cretan mint of Gortyna are remarkable exceptions and important as showing the original nature of inscriptions and of the types themselves. They show that the genitive, which is the usual form of the name when written in full, although nominatives are not very rare, is explanatory of the type.

Types.—The types in the early period are mainly taken from the animal world; they include domestic—particularly the bull—wild animals, birds and insects (the bee at Ephesus); fabulous creatures are also common like the griffin at Abdera, the pegasus at Corinth, the Chimaera, etc.; the vegetable world is also represented, notably by the silphium plant at Cyrene. Representations of the human figure are rarer and later than other types to appear, but once the human head became established as a coin-type, its use spread rapidly and widely and with the disappearance of the incuse square and coming of the double typed coin a head began to be regularly used as one of the types. Complete human figures are rare and are represented either kneeling or standing, both very stiffly like the Poseidon at Poseidonia; the nymph and satyr or centaur common in Thrace (Pl. I.-7) hardly deserves the name of a group; elaborate compositions like the Hercules and Hesperides at Cyrene and the flight of Aeneas at Aeneia are quite unique.

With the coming of legends on coins it was no longer necessary that the main type should be the badge of the town, which is frequently relegated to the reverse or becomes merely a symbol or disappears altogether to give the artist a subject more worthy of his talents. Except in the doubtful case of the earliest electrum, coinage was always a matter for the ruling authority whether civic or regal and the earliest types are chosen to show who these are. That coinage was early recognised as too important a right for private ownership is seen from the traditions which associate all the great law-givers, Pheidon, Solon and Lycurgus, with the institution or improvement of coinage. The sanctity of the republic's right of coinage is seen in the coinage of cities ruled by tyrants, who never put their name or other indication of their existence on the coins, although they occasionally made alterations in the types, as when Peisistratos added the head of Athena to the Athenian coins or when Anaxilos of Rhegium introduced the mule-chariot type in memory of his Olympic victory.

The early types are generally chosen from simple motives. Many of them are a punning allusion to the name of the town like the lion at Leontini, the seal at Phocaea, the goat at Aegae or the quince at Melos, or the sickle-shaped harbour at Zancle. Sometimes it is chosen from the history of a town like the figure of the mythical founder Taras at Tarentum or the Minotaur and Labyrinth at Cnossos (Pl. I.-6). Types like the ear of corn at Metapontum allude to the fertility of the country about. Thrace and Macedon are notable for their huge silver octodrachms with the type of a local hero in a chariot drawn by two bulls. In Italy, Croton takes as its type the tripod of Apollo like its mother city Zacynthus. Poseidonia has a statue of Poseidon brandishing his trident. Naxos in Sicily, whose founders came from Naxos in the Aegean, has a head of Dionysos who was born in the Aegean island. Himera has a cock, a punning allusion to the name of their town for the cock proclaims the dawning of day (*hēmera*). Selinus

has another punning type, the wild parsley leaf (*selinon*). Towards the end of the 6th century B.C., Syracuse introduces the celebrated type of the head of Arethusa, the nymph of a spring in Ortygia, which was in the next century to become the most famous of Greek coin-types. The reverse, a victorious chariot, became a popular one in other towns. The finest specimen of this type of late archaic style is the *Demareteion* (Pl. I.-14) commemorating the victory over Carthage in 480. The head of Arethusa on the obverse wears the laurel wreath of the victorious and beneath the chariot on the reverse is a lion, the emblem of conquered Africa. This type of obverse spread throughout Sicily; the main types of Sicilian towns in the 5th century are local nymphs and river gods. At Catania we have the river god Amenanos; Gela has a manheaded bull swimming, a personification of the river Gelas.

Period II. 480-336 B.C.—The finest period in Greek coinage begins after the Persian Wars and runs to the accession of Alexander the Great in 336 B.C. The first half of this period is transitional and is marked by a great advance in technical skill, an increased delicacy in the treatment of details and greater freedom of movement in the treatment of the human figure. In the last eighty years of this period the art of engraving coins reached the highest standard it has ever attained: the head of a divinity is now established as the obverse type and is usually represented in very high relief—many of the finest are shown facing; the engravers sign their coins which show that they were artists of note and not mere artificers: the names of great artists otherwise unknown have been thus preserved. The types are very varied and almost entirely based on local mythology, although latterly the fine bigae and quadrigae types became popular in allusion to Olympic victories. The type first introduced in Athens—obverse head of a deity and reverse badge of the city—grows increasingly popular and towards the end of the period is almost regular. Inscriptions become general although still frequently contracted. The period is marked by a geographical extension of coining and an increase in its quantity; with the decline of the Persian empire, the cities of Asia Minor, Phoenicia and Syria show an increasing activity; the opening of the mints of Emporiae in Spain and Messalia in Gaul bring the art of coinage to the other end of the known world. Towards the end of the period the rise of Macedon under Philip II. led to the closing of many mints in northern Greece, and his coinage foreshadows the great imperial coinages of Alexander the Great. The second half of the 5th century witnesses a great expansion of the monetary influence of Athens at the expense of her allies.

The coinage of the period is mainly silver; the Aeginetic standard gradually yields to the Attic: electrum disappears except at Lampsacus and Cyzicus and sporadically at Syracuse and Carthage. Gold is continued in the darics of the Persian kings in the east and in the fine series of Lampsacene staters (Pl. I.-10); with the decline of Persian power the Great King's monopoly of gold was usurped by various rulers in Cyprus and Caria. The late 5th and 4th century gold coinages of Syracuse, Tarentum and Cyrene are extensive. Towards the end of the period we have the institution of Philip II.'s gold stater, the first great gold coinage of the world. In the latter part of the 5th century the first copper coins were issued and soon drove out the infinitesimal small silver coins which had hitherto served as small change.

The greatest commercial currency of the 5th century was the silver coinage of Athens, as contemporary references and the huge finds still made all around the Mediterranean show. It was imitated in Central Asia and Arabia which shows the extent of its penetration. The Corinthian stater continued to be an important coinage although its circulation was more limited. The same is true of Cyzicene staters: these great currencies remain more conservative than their contemporaries which are not affected by the same commercial considerations; care is taken to avoid the slightest change, hence the long survival of the now obsolete *koppa* on the coins of Corinth or the archaic use of E for H at Athens.

The feature of the period is the development of the general type—head of a deity on obverse and reverse, the badge of the city—which usually has some reference to the deity also. We find

the latter prevailing in time so that when the old type has no reference to the deity chosen, it is dropped. The gradual abandonment of these old types gave a freer choice to the artist and the simple figures of animals, plants, fabulous animals, etc., give way to mythological groups. Symbols begin to appear on coins and are usually the marks of magistrates or otherwise mark the issues and change constantly. Occasionally we find the old badge of the town relegated to a subordinate position, like the tunny fish at Cyzicus. Names of towns and magistrates are written at greater length and those of artists begin to appear. Types are occasionally labelled like the Zeus at Locri Epizephyrii or the Ajax at Locri Opuntii.

Predominance of Athens.—The causes of the predominance of Athenian currency were firstly the development of rich silver mines in Laurium in the beginning of the 6th century, which provided the money to build the ships which defeated the Persians at Salamis in 480 and secondly the prosecution of her policy of prohibiting silver issues by any city or state that came within her power, whether as tributary or as a member of the alliance in which she was the predominant partner. The members of the Confederacy of Delos while nominally retaining their monetary rights bowed to the practical advantages of a common coinage—which was that of Athens. The fine quality of its silver, the accuracy of its weights and its numerous subdivisions made the Athenian tetradrachm welcome everywhere so that Athens gained the monetary hegemony in addition to the political. In 453 Aegina became tributary to Athens, which at once put a stop to the issue of the "tortoises" and the stater of Aegina practically disappeared from the international market where it had so long competed with the "owls." Eretria on its conquest in 445 lost its right of coinage as did its neighbour Carystus. Tenos, Naxos and other Aegean islands also ceased coining. In Asia Minor, Miletus, Cnidos and other tributaries of the Confederacy issued only small change.

One notable exception is that of Melos, which had refused to enter the League and therefore could still continue its staters. Samos and Lesbos kept up their issues but they were allies of equal status to Athens; Ephesus which entered the Confederacy in 469 continued to coin silver till 460, but there was seemingly some special arrangement in this case. Aeolis, Mysia, and Troas only struck small change. Several towns of the south coast of Thrace, like Abdera, continued their coins but these with their different standards did not compete with those of Athens in the markets of the Aegean. Phocaea, Mytilene and Cyzicus continued their electrum in the 5th century but their silver ceases. The Athenian tetradrachms thus became predominant in the Aegean and beyond, completely ousting local currencies. If we occasionally find autonomous staters, it is a sign of rebellion or shows that the town in question entered the League with special reservations. With the first news of the disasters in Sicily a general defection began and the days of the economic supremacy of Athens were soon over. The Spartans seized the mines of Laurium in 413 and cut off the supply of silver. In 407 Athens was reduced to such financial straits that the gold statues of Victory from the Parthenon were melted down for an emergency coinage; in the next year she had to have recourse to a coinage of bronze which had an unfavourable reception as it could not, like the infinitesimal silver pieces, be carried in the mouth. After being almost extinct, Athenian coinage revived after Conon's successes in 394. On the formation of the second League against Sparta, her allies however struck coins on equality with Athens and used a common type of the infant Hercules with their own reverses and their own standards. Such staters are known of Ephesus, Cnidos, Rhodes, Samos, Cyzicus and other islands and towns of Asia. This diversity of standard in the League shows that there was no monetary convention. Among the rising coinages of this period one of the chief was that of Rhodes (Pl. I-15) founded in 408. Its silver and gold coins have the punning type of the rose and head of Helios. Rhodes had its own standard and its rapidly increasing commerce spread its coinage and standard quickly in the Mediterranean. In 376 Athens regained her hegemony over the islands but for a generation only. Her coinage

again became abundant but never regained a predominance over the numerous local coinages which had sprung up since the end of the 5th century. In addition to Rhodes the important mints of Amphipolis and Larissa begin to issue their beautiful coins and many smaller towns open their numismatic history. The ancient coinages of Samos and Chios disappear before Athenian vengeance in the middle of the 4th century but other towns of Asia and the islands, Cnidos, Ephesus, Tenedos, and notably Cyzicus, testify in their coins to the great prosperity which their autonomy brought them. Corinth and its colonies continued to issue their staters of the old types uninterruptedly up to their conquest by Philip II. and even then did not lose the right of coinage. With this exception however the great revival of autonomous coinage in the early 4th century was short-lived. Philip II. (Pl. I-12) became politically supreme, and economically his gold and silver mines enabled him to drive the gold of Cyzicus and the silver of Athens from the market, but the Attic standard was to survive in the tetradrachm of Alexander. In 404 the people of Aegina after half a century of exile returned to their homes to resume the issue of their celebrated staters but replaced the turtle of the obverse by a tortoise.

The 5th century saw the beginning of one of the finest and most interesting series of silver coins, that of Elis. From about 471 when Elis became a city to its conquest by Macedon in 322 the staters form a continuous series. The whole land was sacred to the Olympian Zeus and his symbols, the thunderbolt or eagle clutching its prey, are usual types along with a Victory in various attitudes—running to crown a victor, standing or seated with outspread wings—the latter type was copied by Pistrucci for the Waterloo medal in 1815. At a later period the head of Zeus appears as does that of Hera and also the fine head of the nymph Olympia. The legend is always FA for (F)aleion and the long obsolete digamma survived to the end of the coinage in the middle of the 1st century B.C. The types and the additional legend *Olympikon* occasionally found show a close connection with the Olympic games which the Eleians claimed to control. There is an interesting numismatic record at Pisa of the successful effort on the occasion of the 104th Olympiad by the Pisatans to regain their ancient right of controlling the games which they had lost when the Eleians destroyed their city in 572 B.C.

Italy and Sicily.—It is in the west in Italy and Sicily that work of the finest period is seen in greatest profusion. In Italy, Tarentum, the capital of Calabria, continued its type of Taras on a dolphin on its silver. In the middle of the 5th century the agonistic type of a horseman appears and Taras is relegated to the reverse; the celebrated Tarentine cavalry are thus commemorated down to the middle of the 4th century. About 340 Tarentum issued a series of very beautiful gold coins with a head of Persephone and, reverse, the infant Taras appealing to Zeus enthroned. These gold coins, like sudden issues of gold elsewhere, were really a money of necessity.

In Lucania, Heraclea, founded in the middle of the 5th century, issues fine staters with a helmeted Athena and Heracles seated, strangling, or wrestling with a lion. Metapontum interrupts the monotony of its ear of corn type with a most striking head of its founder Leucippus. Other mints of the time are Neapolis, with its types the siren Parthenope and her father, the manheaded bull Archelous; Velia, with its head of a nymph and reverse the eastern type of a lion attacking a bull; Thurium, with its unusually fine head of Athena and the powerful bull on the reverse, and Terina, remarkable for its beautiful treatment of the Victory type.

It is in Sicily, particularly in Syracuse, that the engraver's art reaches a perfection never attained elsewhere before or since; from the middle of the 5th to the middle of the 4th century every coin is the work of an artist. In the 5th century Syracuse began to dominate the politics of Sicily as Athens was doing in the Aegean, and her artists spread the influence of her coin-types everywhere. The coins of Syracuse showed many varieties of the heads of Arethusa and Persephone and the chariot of the reverse was found capable of very varied treatment. After the middle of the 5th century her artists began to sign their work and we

Solidus of Theodosius. 21. Solidus of Justinian. 22. Solidus of Justinian II.

can thus prove, what is frequently obvious, that other towns borrowed engravers from Syracuse. The Syracusan coinage is mainly silver. During the siege by the Athenians, beautiful little gold coins were struck with reverse Hercules strangling a lion (Pl. I.-22). With the prosperity following the enemy's defeat, Syracusan art reaches its zenith. As the *Demareteion* commemorates the defeat of the Carthaginians so the great series of decadrachms perpetuates the victory of 412. The agonistic types and word *athla* on some of them show that they were distributed at the games held to celebrate the victory; their types were widely copied and their engravers Kimon and Euainetos—otherwise quite unknown—have gained a place among the world's greatest artists. In the 4th century the coinage becomes somewhat stereotyped and has no longer any originality. We may note the issues of electrum by Dion in 357-353 and of gold by Timoleon who introduced the Pegasus type from Corinth on his coinage.

Among other cities of Sicily we may note the fine series of Agrigentum of the 5th century with its beautiful double eagle type and the Camarina type of the river god Hipparis and the nymph Camarina on a swan; Himera before its destruction in 408 issued some very interesting types such as the nymph Himera sacrificing while Silenus beside her bathes at the thermal spring for which Himera was noted,—or Pelops in his chariot, referring to a victory of a Himeran at the Olympic games which Pelops is said to have founded. Segesta, Eryx and other cities already Carthaginian, use Greek types and artists but have Punic legends. The nymph Segesta and the river god Crimissos are the best types of Segesta while Selinus abandons its parsley leaf and issues a number of very remarkable types, notably that of Apollo and Artemis in their quadriga with reverse the god Silenus sacrificing at an altar, a type which refers to the cessation of the plague as a result of appeals to Apollo as healer. In conclusion we may mention the wonderfully realistic Silenus with his wine-cup at Naxos.

Period III. c. 336-c. 100 B.C.—Alexander's conquest considerably extended the sphere of Greek influence and in this period there is a further extension of coinage. Egypt, hitherto coinless, now produces the richest series of the Hellenistic period. Bactria and Parthia too strike Greek coins. Spain and Mauretania begin to issue coins; in the north the Gauls, Britons and Germans begin early in the 2nd century to imitate Greek coins and soon learn to strike more independent issues. The influence of Alexander's coins (Pl. I.-13, 17) is decisive in the coinages of his successors in their different kingdoms. Only a few free towns strike their own silver and even they tend to use Alexandrian types. The period produced a number of coins of alliances like the Achaean and Thessalian Leagues. In the west the gradual advance of Rome is reflected in the coinages; local silver ceases earlier in Italy and Sicily than in Greece and Asia.

The accession of Alexander the Great in 336 inaugurates a new epoch in coin-types. The main feature of the period from his accession to the conquest of Greece by Rome is the final establishment of the portrait coin as the regular type of a currency and the great preponderance of regal issues.

The portrait of a living monarch took nearly a century to establish itself on a coin. Philip II. and Alexander the Great issued vast coinages throughout the ancient world but were content to put their name alone on the coin—latterly Alexander added the title *Basileus*. After his death his deified portrait appeared on the coins of Lysimachus in Thrace and on the early coins of Ptolemy I. in Egypt. It is not till 306 that we have a portrait of a living king on his coins when Ptolemy I. appears, still as god with the aegis of Zeus. Seleucus I. similarly puts himself on his coins as Dionysos; in time the divine attribute is dropped and the ruler appears as a mortal wearing only the royal diadem. In Macedon Arrhidaeus, Cassander and Antigonos still follow the types of Alexander and the early coins of Demetrius Poliorcetes (306-283) are without a portrait. Soon however his own portrait appears, still with the horns that deify him. His successors only have types of deities. Pyrrhus does not appear on any of his extensive coinages but the last two kings of Macedon, Perseus and Philip V. have left very fine portraits. The

kings of Pontus notably Mithridates VI. have a magnificent series of portraits. The kings of Pergamon use the same portrait throughout, that of the founder of the dynasty, Philetairos I., and the Ptolemies in Egypt throughout their long series use only the head and legend of Ptolemy I. (Pl. I.-20), except on certain special issues (Pl. I.-21). Among the early Seleucids Antiochus I. was reluctant to drop the portrait of Seleucus I., but the portrait of the reigning monarch becomes the rule in this series (Pl. I.-18); farther east we have the long series of portraits of the Arsacids and the unparalleled series of Bactrian and Indian kings (Pl. V.-1). The smaller series of Persis give some portraits, but they rapidly become stereotyped as do the coins of Elymais and Oman. The Jews (Pl. II.-4) with that strict interpretation of the second commandment as is later the case among the Arabs have no portraits, but the Nabathæan kings have.

The reverse types also show the influence of Alexander; seated deities become common and go back to the Zeus on the tetradrachms of Alexander (Pl. I.-17), or standing deities which go back to the Nike on his gold (Pl. I.-13). The Seleucids have commonly a seated Zeus or Apollo. The Parthian series is unusual—the reverse shows the king seated, (perhaps) Arsakes I. the founder of the dynasty, treated with the respect due to a deity. The king's name remains on the reverse in keeping with its development as the successor to a town name and does not yet appear alongside of the portrait. The ancient world did not know the custom of numbering kings of the same name; they are as a rule sufficiently distinguished by their epithets.

After the vast issues of gold by Philip II., Alexander and Lysimachus, gold is but rarely struck, except in Egypt. Silver is the general metal of coinage and the Attic standard, which Alexander had adopted for his tetradrachms, became the monetary standard of the world, except in Egypt; there is a great increase in the bronze coinage, the local issue of which does not seem to have been seriously restricted by sovereigns and suzerains.

As the greater part of the Greek world was now ruled by the Diadochi, their various coinages naturally formed the main currencies of commerce. A number of civic and other coinages still survived however. Third century Athenian coinages are scarce except in bronze; occasionally as in 296 the issue of gold shows the straits to which the once wealthy city was come. In 229 when Macedon lost its supremacy over Athens and friendly relations were established with Rome a new era begins with the abundant issue of tetradrachms of the "new style" (Pl. I.-19) which went on for two centuries. The Athena of these coins is not the old one but a copy of the head of the Parthenos of Phidias and the owl on the reverse is now perched on a Panathenaic amphora. The AOE still remains but a number of new legends and symbols are added to the reverse chronicling a long series of magistrates. Much light is thrown on the organisation of the Greek civic mints from these names and symbols. The other great coin issuing city, Corinth, went on striking its stater till 229 when by its surrender to Doso the long series came to an end.

Rise of Rome.—The Roman conquest of Greece is reflected in the coinages. When the Romans overthrew Philip V. in 197 or Perseus in 168 they professed to be restoring the liberties of the Greeks and it is clear from the resumed activity of the mints that the Greek cities were autonomous in one respect at least. After the defeat of Philip V. the Thessalians formed a confederation with silver coins of the type of Zeus and Athena and the legend *Thessalōn*; a similar coinage was issued by the Boeotians. With the final overthrow of Macedon at Pydra in 168 begins the extensive issue of tetradrachms of Maronea and Thasos which became a great commercial currency for trade with the Barbarians across the Danube who continued to imitate them. Macedon itself as a Roman province issued tetradrachms bearing the names of Roman governors. In Asia after the defeat of Antiochus III. at Magnesia we have an outburst of tetradrachms of Attic weight and local types at towns like Lampsacus, Smyrna (Pl. II.-1). Magnesia and many others. Other cities similarly resumed the issue of Alexander tetradrachms, adding a small symbol to mark the town of issue—Miletus, Samos, Rhodes and many other Asiatic cities. These Alexander types continued down

to the middle of the 2nd century when the Roman province of Asia was set up and the *cistophori* replaced them. The first *cistophori*, so called from the Dionysiac chest which formed the principal type, were first struck at Ephesus at the end of the 3rd century; the reverse is a bow in quiver between two serpents (Pl. II. 3). The Pergamene kings popularised them and the Romans thus found it easy to substitute them for the Alexandrine tetradrachms with their undesirable associations. *Cistophori* were now struck in many Asiatic mints and bear the monogram of the town of issue. The last stage in the Roman conquest of the east was the defeat of Mithridates and those towns that had assisted him had their coins replaced by *cistophori* with the exception of Athens which obtained favoured treatment. The fact that Rhodes resisted Mithridates and assisted Sulla enabled its autonomous silver coinage to survive down to the Civil War:—it was the last autonomous coinage of Greece.

In the west the rise of Rome in the 3rd century introduced a new factor into the history of Greek coinage. The first coinage to disappear was the Etrurian after a life of two centuries. Rome's early intercourse with the Greek cities of Italy is reflected in the Romano-Campanian coinage. In the south the Italian campaign of Pyrrhus left its mark on various coinages, notably at Tarentum which also has some exceptional numismatic records of Hannibal's occupation. The towns of Magna Graecia gradually lost their silver coinage under Roman influence although their bronze lasted till the 1st century.

In Sicily in the 3rd century Syracuse began to dominate the whole island in coinage as well as politically; the types are mainly imitations of those of the 5th and 4th centuries; the coins of the other towns have little claim to originality. The Punic Wars brought the Romans to Sicily where the Carthaginians had been established since the end of the 5th century and had struck coins of Syracusan and other Sicilian types with Punic legends and later with their own types. When Syracuse fell to Rome in 210, Sicily became a Roman province; henceforth only bronze was struck in it; these local coins continued into the first century, when the last trace of Greek coinage in the west disappears.

Period IV. c. 100 B.C.—A.D. 268.—Under the Romans many Greek cities and districts continued to issue their own bronze coins but the geographical area over which this was done became considerably restricted under the empire. In the west—Italy, Gaul, Spain and North Africa—the right of coinage was abolished quite early in the empire, the latest local issue of these regions being a coin of Babba in Mauretania of the reign of Galba. In the east, particularly in Asia, these local bronze coinages went on down to the time of Gallienus in 268, when the complete depreciation of the Imperial silver coinage, now bronze washed with silver, made the issue of bronze for small change pointless. The language of the inscriptions is Latin in the west and Greek in the east—with a few exceptions in the latter case. The Imperial gold (*solidus*) and silver (*denarius*) became the main currencies throughout the Roman empire.

Before dealing in general with the bronze of the Greek cities, we may note one or two local subsidiary silver coinages issued by the Roman emperors in continuation of important pre-conquest coinages. The largest series of these was the Egyptian or Alexandrian series which runs from Augustus to Diocletian. In addition to bronze, this series at first included tetradrachms of billon of gradually decreasing fineness, which continued the tetradrachms of the Ptolemies; later it is of bronze only. The legends are always in Greek; the coins bear the emperor's head on the obverse and the reverse types are at first usual Roman types but after the end of the first century begin to include native Egyptian types in increasing numbers, often of peculiar interest. The reverses are dated in regnal years in Greek numerals. From the reign of Claudius II. there is only one denomination, a small thick bronze piece originally coated with silver, which is probably still the commonest of all ancient coins. The earlier bronze which occasionally, although not generally, rival the work of the Roman mint have in the 2nd century a characteristic bevelled edge.

In Syria silver tetradrachms continued to be struck, mainly at

Antioch but also at Tyre and a few other mints. These gradually became baser in the course of the early third century. Copper was also struck by the Romans at these mints and frequently bears the letters S C showing that this issue, as in Rome, was the prerogative of the Senate. Of several other local silver coinages the large series of drachms struck at Caesarea in Cappadocia from Tiberius to Commodus is the most important. The usual type is a local one of Mount Argæus but common denarii reverses are also found.

A number of vassal states and protectorates continued to issue their own coinages in the precious metals until they became Roman provinces. The only gold coinage of this kind is that of the kings of the Bosphorus who struck coins from the time of Augustus to the beginning of the 4th century with the Roman Emperor's head on one side and the local dynast's on the other. This coinage becomes gradually debased, passing from gold to electrum then to silver and billon and ultimately to copper in the 3rd century A.D. At the other end of the world, the kings of Mauretania continued to strike their own gold and silver until it became a Roman province in A.D. 40.

Bronze Coinage.—We now come to the regular series of Imperial Greek bronze coins which close the thousand years of Greece's numismatic history. They have no claim to artistic merit and are of local workmanship; therein they form a contrast to the regular Roman coins of the time which frequently attain a very high level. If they are devoid of artistic interest they have a very high historical and archaeological value.

The right of coinage is sometimes continuous and sometimes intermittently permitted by the Emperor or governor. Sometimes the right is held alternately by pairs of towns as in Moesia by Marcianopolis and Nicopolis. Coins are struck not only by single towns but jointly by alliances of towns (*homonoia*).

The general type is everywhere the same; obverse a bust and reverse a type of local interest. Under the Republic the Greek cities usually placed on the obverses of their coins an allegorical bust,—that of some local hero or of the "people" the "Senate" or the local city-goddess. The People (*Demos*) in Asia Minor is usually personified as a young male bust; the municipal council (*Boule*) and the Senate (*Sunkletos*) appear as young veiled females. The Tyche of the city appears as a female bust wearing a mural crown. The goddess Roma is found as a helmeted female, e.g., at Smyrna. Pergamon and other towns of Asia Minor have Poseidon. Athena, Apollo and other well-known divinities are also found on the obverses.

Under the empire the usual obverse type is the head of the Emperor as on the regular Roman series. There are some notable exceptions. Macedonia for example had the head of Alexander the Great. Athens was privileged by Hadrian to use the head of Athena in place of the Emperor's. These are exceptions; the usual type is the bust of the Emperor and the obverse legend gives his name and titles in Greek, usually transcriptions or translations of his Latin titles, with occasionally some local allusion. The reverse type is reserved for the town of issue and the date when given is in a local era. The name of the town is in the genitive plural of the ethnic, very frequently with the addition of some proud epithet, of more or less significance. These epithets are of various kinds; many refer to the emperor either to flatter him or in memory of some benefit received. Some recall the origin of the inhabitants; Blaundus in Lydia, for example, calls itself Macedonian because it was originally a colony of Macedonian soldiers. Very favourite adjectives are "autonomous" and "free" but the most highly prized is that of *Neokoros*, which in Imperial times signified that the town had built a temple in honour of the Emperor. Ephesus for example proclaims in the reign of Caracalla that it had built 3 imperial temples. Capitals of provinces call themselves *Metropolis*; the title "first city" of the province is also highly prized and occasionally disputed, as we see from the coin-legends of Nicomedia and Nicaea in Bithynia or of Smyrna and Ephesus in the province of Asia. Towns in Phoenicia and Syria which had a temple with the right of asylum call themselves *ἐκὴ καὶ θεῶδος*: a number of maritime towns bear the title *ναυαρχίς* officially granted them by the emperor in recognition

of their naval importance. Damascus calls itself "illustrious," Syedra "brilliant," Nicaea "greatest and best" and there are many such empty titles.

Besides the ethnic these coins very often bear the names of magistrates and other officials; in the early years of the empire these include a few governors and other officials sent from Rome, some of whom even have their portraits on their coins, like the younger Cicero at Magnesia. But throughout the series the names and titles of local magistrates are vastly more common. These throw a good deal of light on local life and administration.

It is the reverse types of this series of coins that give them their importance. The coins of Athens preserve representations of many statues famous in antiquity which have long since perished such as the Athena Parthenos of Phidias, the great Athena Promachos on the Acropolis visible far out at sea, or the Dionysos of Alcamenes. A coin of Elis preserves for us the Olympian Zeus of Phidias and Lacedaemon the Apollo of Amyclees. Local cults are everywhere illustrated and incidents in the lives of all the divinities of Greek mythology are common types. Not only do we have gods and goddesses but also all kinds of local deities like river gods and nymphs. Local celebrities are also recorded; thus we have Homer at several of the various towns that claimed him as a native notably Smyrna, Anacreon at Teos, Sappho at Eresos in Lesbos, Herodotus at Halicarnassus, Alcaeus at Mytilene which records on its coins a whole series of its famous men, the majority of whom are not otherwise known. Not only are famous Greeks commemorated; the travels of Hadrian in the provinces led to the issue of many specially fine coins, some of which bear the portrait of his favourite Antinous.

Agonistic types are very numerous on account of the great part played by games and festivals in the life of the time. Their celebration is frequently recorded on coins; sometimes we learn that the town was not able to bear the expense and that officials or private individuals were ready to bear the expense in return for the honour of presiding and this is duly chronicled. In addition to the four great Hellenic Games we find many of more recent origin instituted in honour of the Emperor, like the Actian games in honour of the victory of Augustus at Actium, celebrated at Tyre and other towns, the Philadelphian in honour of Caracalla and Geta at Nicaea, etc., or in honour of local deities like the Panathenaic at Athens, or the Heracleian at Perinthus commemorated by a series giving the labours of Hercules. When two or more cities combined to have a joint festival, this is commemorated by a joint issue of coins. In conclusion we may mention a notable example of the preservation of a local tradition on a Greek imperial coin. On a coin of Septimius at Apameia in Phrygia we have as reverse type a man and woman in a chest or ark floating on water with a raven on the top and a dove flying above with a branch in her beak; to remove any doubt as to what scene is represented the ark is labelled ΝΩε and the coin is evidence of the local tradition that the ark rested on the mountain behind Apameia (Pl. II.-2).

ROMAN COINS

It was comparatively late in her history that Rome emerged from obscurity and became a great city. The adoption of a coinage was one of the most significant signs of the change. In very early times Rome had reckoned values in oxen and sheep, hence the word *pecunia* (money), from the same root as *pecus* (head of cattle). Later she began to use bronze as a means of payment,—but as yet only in rough, unstamped lumps (*Aes rude*), not as coins. The later tradition represents her as ridiculously poor in the precious metals, and the little that we know confirms it.

The exact date at which Rome passed on to the use of metallic currency is subject to some doubt. It is certainly not earlier than 338 B.C. (the date proposed by E. J. Haeberlin), and a strong case can be made for a date rather later. The Roman authors, who attributed the innovation to the king Servius Tullius, had no real knowledge of the facts. The first pieces issued were heavy cast coins of bronze (*Aes Grave*) representing the *As*, the unit, a pound of bronze and its subdivisions—*semis*, ($\frac{1}{2}$), *triens* ($\frac{1}{3}$),

quadrans ($\frac{1}{4}$), *sextans* ($\frac{1}{6}$), *uncia* ($\frac{1}{12}$)—a cumbrous coinage that needed wagons to transport it. It seems to be a clumsy attempt to apply the Greek institution of coinage to the bronze system of Italy. But very soon afterwards silver also was issued in the Roman name; its superior convenience was soon felt and, after the First Punic War at latest, it ranked as the chief metal in the Roman market.

The earliest Roman silver coins were *didrachms* struck on a standard familiar in Campania and issued in part at least in that district. They are coins of a normal Greek pattern and with the small token bronze that accompanies them, were clearly meant to circulate in districts accustomed to Greek coins—that is to say in Campania and its neighbourhood, Lucania and Bruttium and to some extent Samnium and Apulia. The coinage, whether we regard it as primarily military or commercial, certainly arose in the course of the great wars, which ended in making Rome supreme in Italy by about 270 B.C. It represents one result of the closer contact of Rome with the Greek south.

The *Aes Grave*, to a large extent, runs in series parallel to the silver, but can hardly have circulated in the same districts. It is simplest to regard it as the counterpart of the silver coinage, issued for Rome and her Italian allies, in North Italy, Latium, the Sabine country and, to some extent, Samnium and Apulia. As Haeberlin has demonstrated, Rome's first system of coinage is a dual one: it is only unified, when the more cumbrous Italic system yields to the Greek. Our knowledge of details is as yet very imperfect. There are variations in the weight of the *As* or pound, which do not answer to any obvious explanation; there is a reduction in the weight of the *didrachm*, which may or may not be due to inflation in the Pyrrhic War. We do not know how the *didrachm* and the *As* were related. Fortunately, the historical meaning of the coinage is clear. Rome began to open her doors to Greek ways and she was soon followed by her colonies in the South—Cales, Suessa, Teanum, which struck *didrachms* like hers—and by other colonies, in districts less Greek, which cast *Aes Grave*—Hatria in Picenum, for example, and Luceria in Apulia, or by independent cities such as Iguvium and Tuder in Umbria.

It was under the strain of the Punic Wars that Roman Republican coinage assumed the form in which we know it best. The *denarius*, traditionally assigned to 269–268 B.C., replaced the *didrachm* as the main Roman silver piece; it was equal in value to 10 asses, while its half, the *quinarius*, equalled 5, its fourth, the *sestertius* 2½. The *As*, originally a pound in weight, was reduced to about 5 oz.; then by slow descent to little more than 3 oz., again to 2 oz. and finally to 1 oz. Gold was issued on two separate occasions, as an emergency coinage—once in 217 B.C., once perhaps earlier. One fact, which has been obscured by modern writers, is the issue of *Aes Grave*, with the reverse type, in great masses during the First Punic War; Rome was short of silver and fell back upon her native Italian bronze and the strain of the war led to inflation, expressed in the reduction of the weight of the bronze unit, the *As*.

By the end of the Second Punic War Roman coinage had assumed its lasting form. The *denarius* was without question the master coin. Second to it in importance came a second silver piece, three-fourths of it in weight, the "Victoriante" or "Victory coin," struck for foreign trade in the Western Mediterranean, South Italy and the Adriatic. It may only have been introduced just before or during the Second Punic War. The *As*, now reduced to one ounce, was a tenth of the *denarius* in value. Pliny has recorded a change of tariff to sixteen to the *denarius* in the Second Punic War, while admitting that the value of ten to one still held in the pay of the soldiers. As the coins themselves only show the new value much later, we are uncertain how far Pliny can be trusted. There was no gold coinage except in case of emergency.

The political supremacy of Rome in Italy afterward found expression in the supersession of all other Italian coinages, except a few of token copper in the South, by the Romans. This change did not take place very early or all at once—and favoured allies, such as Naples or Velia, probably coined in their own name longer than the Latin allies, with their closer bond with Rome: it was

probably hardly complete before the end of the Second Punic War.

In the great period of expansion after 200 B.C., denarius and victoriates went out to conquer the markets of the world. In the West progress was rapid, but the East, with its abundance of coinage, offered a successful resistance. Rome in her Eastern wars learned to use Eastern currencies, gold staters of Macedon and silver tetradrachms of Athens or Asia, and brought them into her own service: it was thus that she could dispense with any gold coinage and be content with a silver piece of less value than a shilling. About 135-130 B.C. the value of the denarius was raised to 16 asses, in place of 10, and, after a period in which the two values conflicted, that of 16 won the day (c. 100 B.C.). The great Social War of 91-89 B.C., when the Italian allies almost overthrew Rome in their eagerness to share her citizenship, led to confusion and inflation. The policy of the Gracchi, with its demands for land settlement and foreign colonies, had necessitated great issues of money, and, as early as 122 B.C. the senate had begun to inflate, by issuing base, plated denarii among the good ones. This policy was now vastly extended: the silver became so mixed and impure, that no one could tell what he really possessed. To add to the confusion the As was reduced from 1 oz. to $\frac{1}{2}$ oz.; and, finally, in 87 B.C., the state declared itself bankrupt by ordering that all debts should be cleared at five shillings in the pound (*quadrans* for As). A praetor, M. Marius Gratidianus, attempted to find a remedy by sorting out the good denarii from the bad: at the same time, a new coinage of pure silver (theoretically pure, at least) was issued. Sulla, however, on his return and triumph, butchered M. Marius and annulled his policy, insisting that the money of the state must be accepted at its issue value: but, in future, the senate used its powers with strict moderation. The bronze coinage was allowed to sink into the background. The only further development of the Republic was the introduction of a permanent gold coinage by Julius Caesar, after previous experiments by Sulla.

The control of the coinage was in the hands of the senate, acting for the sovereign people; major changes had to be sanctioned by the passing of special laws. The responsibility for the striking of coins was normally entrusted to a special commission of three, "tresviri aere argento auro flando feriundo," but also, if less commonly, to other officials, such as quaestors or curule aediles. Roman coins were issued not only at Rome, but also at other mints in Italy and, later, in the provinces. But it is probable that these outside coinages were not at first administered in any way differently from the home and that issues outside Italy occur but rarely until the time of Sulla. In the period after Sulla these provincial issues became more and more important and less and less dependent on the senate. The generals abroad assumed the right to issue money to their troops in their own name and the senate raised no objection. In the end this military coinage of the provinces gave birth to the imperial coinage.

Roman coinage was historical in a sense in which modern coinage is not, but it is only late in the Republic that this element becomes strong. Rome began by placing on the obverse of her denarius the helmeted head of Roma, the protectress of the city and on the reverse, the Heavenly Twins, Castor and Pollux, who "fought so well for Rome" at the battle of Lake Regillus in 494 B.C. These types, with their somewhat general reference to Rome's divine protectors, remained in vogue for more than a hundred years. Variety first began in the reverse types, when figures of deities driving chariots began to replace the Dioscuri—Diana or Victory driving a biga or Jupiter or Apollo driving a quadriga. From about the time of the Gracchi an even greater freedom begins to prevail, and, extends to the obverse as well. In the succeeding period the types vary from issue to issue, with rare and passing revivals of traditional types. The choice is dictated by two considerations (1) the family pride of the moneyer, who selected incidents of interest from his family history (2) a natural interest in current politics, which leads the moneyer to select such types as can be brought into relation with current events.

A few examples will illustrate these tendencies. Sex. Pompeius Fostlus strikes a reverse, showing his ancestor Faustulus, the

shepherd, finding the twins, Romulus and Remus, with the she-wolf; he probably strikes in the days of Tiberius Gracchus, when the thought of Roma Renascens, the "re-birth of Rome" was in men's minds—hence an appropriateness in the reference to her origins.

A group of moneyers of the year 118 B.C. issuing coins for the new colony of Narbo in Gaul, put on their reverses a Gallic warrior, probably Bituitus, king of the Arverni, in his war-chariot: in this case the public interest in Gaul has displaced any personal references. L. Tiburius Sabinus, striking c. 87 B.C., refers to the legendary Sabine king, Talicus, and to the rape of the Sabine women: the parallel between Rome's troubles with her neighbours in the past and in the present was obvious to all. Sulla, in the East, struck gold coins, with obverse types of Venus, whose favourite he claimed to be: later, in Rome itself, he commemorates his own triumph. Pompey the Great, perhaps in 61 B.C., struck a similar coin in honour of his Eastern victories, with a glance too at Africa, where his career of triumph had begun. The twenty years from 70 to 50 B.C. yield a host of references to history. M. Lepidus, probably the man who was afterwards triumvir with Octavian and Antony, has a gallery of family types, celebrating an earlier Lepidus, who at the age of 15 killed an enemy and saved a fellow-countryman in battle; the Marius Lepidus, who was sent to Alexandria to be tutor to King Ptolemy V. of Egypt in 200; the vestal virgin Aemilia, for whom Vesta miraculously rekindled the sacred fire; the Lepidus who restored the Basilica Aemilia and hung it with shields in 78 B.C. A. P. Hypsicrus goes back still further to Neptune and his daughter, Leucrooe, the origin of his line.

With the outbreak of the great Civil War, the personal element burst out into full prominence. The coinage of Julius Caesar from the first bears the stamp of his personality and in the last year of his life the senate authorized him to place his portrait on the coins. Hitherto, the obverse of the coins had been considered the prerogative of a god or goddess: at the most, room might be made there for a hero of early days, such as Scipio Africanus. Caesar's own generation had begun to engrave the portraits of its fathers and now, at last, the portrait of the living man appears. Rome had come back to the monarchy, by whatever name she might call it. From this point to the end of the Republic, we have no true Republican coinage but only the preparations for the Imperial. Even the murderers of the tyrant Caesar in their last struggle for the Republic in the East, placed their own portraits on their coins. Brutus, on one famous reverse, set the daggers that had stabbed Caesar, with the comment EID. MAR. (the fatal Ides of March). Antony strikes in the East associating with himself first his wife in Rome, Octavia, later his Egyptian enchantress, Cleopatra. For his army and navy before the battle of Actium, he strikes denarii with the eagle and standards and prow on the reverse. Sextus Pompey, the pirate son of Pompey the Great, celebrates his chief naval victory over Octavian by a coin showing him as "son of Neptune"—proud title of a successful admiral.

The Roman bronze coinage never outgrew its conventional types. It grew to importance in the First Punic War, when the reverse represented the prow, the sign of sea power, the obverses the great gods of the state. These types it kept throughout: the ordinary Latin word for the "tail" of a coin is "navis" (ship).

Augustus.—The Empire, founded by Augustus, has a dual aspect; on the one side it is a monarchy, based on the support of the troops; on the other it is simply an exalted magistracy of the Roman Republic, created with special powers to deal with special problems. The imperial coinage faithfully mirrors this duality. The Emperor, as paymaster of the soldiers, keeps in his own hands the issue of the precious metals; but he leaves to the senate, now the one representative of the Roman people, the right of issuing the token coinage of brass and copper. The mint of the senate is naturally in Rome itself. The imperial mint is early centralised in the same place, but it is important to note that Augustus began by striking his money for the troops in the provinces, continuing the practice of the generals of the late Republic. His mint was not the successor of the senatorial, but

a new creation of his own. It was probably Caligula who opened the first mint in the capital. Henceforth gold and silver was normally struck in Rome. Provincial issues occur freely in times of civil war, but hardly to any extent otherwise. It was only in the 3rd century that a number of provincial mints came into being, to meet the needs of the chief armies. Antioch in Syria among the first. The example once given soon spread. By the time of Gallienus, imperial coins were struck in Viminacium, Siscia, Lugdunum, Mediolanum—perhaps at other mints too—as well as at Rome and Antioch; and from Aurelian on, the principle of the local issue of imperial coins is dominant. The senate struck mainly in Rome—at first only for Rome and Italy. The mark S.C., “senatus consulto,” attests its authority. Antioch in the East and Lugdunum in Gaul also issue coins with this mark, which we must regard as also issued under senatorial authority. After the first two Emperors this coinage was probably current over the whole Empire; but it never played any large part in the East.

The commission of “tresviri” of the mint continued to exist as late as the 3rd century; but the names of these magistrates cease to appear on the coins before the death of Augustus. They may still have played a part in the senatorial issues; the imperial coinage fell within the range of the chief imperial officer of finance, the “a rationibus,” and, under him, were administered by imperial procurators. The actual striking was entrusted to a staff of imperial freedmen and slaves. From an early date the Emperor began to exercise a controlling influence over the bronze token coinage also. The two mints may after a time even have been housed in the same building; at any rate the authority of the senate came to be more and more an empty form.

The Roman Republic had only known gold as an emergency or as a foreign coinage. Augustus from the first made his standard gold piece, the “aureus,” the head of his system. The denarius however continued to be struck pure and of unimpaired weight; the coinage rested on a bi-metallic basis. The aureus weighed the forty-second part of a pound, the denarius the eighty-fourth; twenty denarii went to the aureus. The token coinage consisted of the sestertius and the dupondius, struck in brass, the fourth and the eighth part of the denarius respectively. The as, the fourth of the sestertius, and the quadrans, the fourth of the as, were struck in copper. Gold and silver were both struck almost pure. Base, plated denarii were not uncommon, but were the work of forgers. Under Caligula and Claudius, however, there is reason to think that the government abandoned its sound principles and condescended to make an unlawful profit by this device itself.

Later Imperial Changes.—Nero reformed the coinage, reducing the weight of the aureus to the forty-fifth part, that of the denarius to the ninety-sixth part of a pound. More important still, he added ten per cent of alloy to the hitherto pure silver. The relations of the coins to one another remained unchanged. Various more or less respectable motives for this reform have been suggested; and, so far as concerns the reduction of weight, there may have been justification for this measure of inflation. It is impossible to judge the debasement of the silver so charitably. It can be nothing but a device of a spendthrift government for meeting its obligations cheaply.

The evil consequences of Nero's debasement were slow to make themselves felt; but they were nevertheless disastrous. Again and again under stress of circumstances the government resorted to the same expedient. The percentage of alloy in the silver rose to as much as forty per cent under Septimius Severus.

Caracalla took the next step. He reduced the weight of the aureus to a fiftieth part of the pound and issued a new silver coin, the “antoninianus” or double denarius at the weight of about a denarius and a half. In the following period the aureus continued to decline in weight and the denarius, after a struggle, succumbed to the less honest double piece.

A final debasement of the silver by Gallienus at the crisis of his reign, when Valerian was a Persian captive and the West cut loose under an Emperor of its own, overtaxed the patience of a long-enduring public. The Antoninianus was no longer taken at its

nominal value; confusion reigned and prices rose to absurd heights.

It was Aurelian, the “restorer of the world,” who stabilized the coinage. The details of his work are obscure; what is certain is that his stabilization was so unpopular that it led to a riot, on the scale of a miniature civil war in Rome. A coin like the antoninianus was struck, but its value was reduced far below par. Gold was not restored on a reliable basis and the process of inflation began again. Diocletian had no choice but to deal summarily with this problem, before he could restore a coinage that deserved confidence.

Non-imperial Coinages.—In the West, local coinage in South Italy, Sicily, Gaul, Spain and Africa is found commonly under Augustus and Tiberius and sporadically, down to Galba. When this local coinage ceased, the duty of supplying the whole of the West fell on the mints of Rome, sometimes assisted by branches at Lugdunum (Lyons). In the East the case was very different. Coinage had been known there for so long, that the Romans found it expedient to leave a large part of the issues to local mints. Provincial silver or billon was struck in Asia, at Caesarea in Cappadocia, at Antioch in Syria, and at Alexandria in Egypt. Small change was issued freely not only in a number of provincial issues, but also at a vast number of city mints. It may fairly be said that the right to issue such small change was freely granted to almost every urban community. Under these circumstances the part assigned to imperial coinage was a restricted one. The aureus, indeed, had hardly a rival, the denarius circulated beside the provincial silver; but the token coinage in use was almost exclusively of local make. Not till late in the 3rd century did this local coinage succumb before the debasement of the imperial silver and the opening of provincial mints for imperial coin. The provincial coinage was, in its degree, a concern of the imperial government; the local coinage, however, was in theory independent. Its types are largely taken up with local interests; and, although reference to the Emperor or senate or people of Rome, is common, it is by no means universal and expresses a compliment rather than a definite acknowledgment of sovereignty.

Portraiture.—We have seen how under Julius Caesar interest in the living individual found expression on the coins in the form of portraiture. This tendency was developed to an immense degree under the Empire; but, as was only natural, interest was now focussed on the Emperor himself and the members of his family. Beside them there was no room for individual distinction. The Emperor, as head of the state, enjoys the right of portraiture on the obverse—a right which extended, at first sparingly, later more freely, to living Emperresses or princes or to deceased members of the line. The reverse types, too, are full of his personality and his prowess. His victories, his triumphs, his distributions to the poor of Rome, his public shows, his measures for the welfare of Italy or the provinces, his arrivals and departures, his marriages, the birth of his heirs, his provision for the succession—these and many more, find constant reference on the coins. It is significant of the growth of imperial influence over the senatorial coinages, that, after a time, such reference is found as freely on the bronze coinage as on the gold and silver.

Religion still plays a large part. But even the great gods of the state are freely brought into connection with the Emperor and his protectors or as types of his qualities; and what is true of them is even more true of the minor deities, or virtues, who were so widely worshipped by the Romans. The virtues of the Emperor provide a symbolism fit to cover the whole of the imperial administration; his valour and victorious power, his care for the corn-supply of Rome, his spirit of constitutionalism, his liberality, his justice and his mercy. The coinage has throughout a strongly propagandist character. It serves to make known the achievements and to advertise the policies of the government.

The imperial system produced its own cult, the worship of those Emperors who, after death, were adjudged worthy of the honour of consecration. The worship of the “divi,” as these deified Emperors were called, bulks large on the coins. They wear the radiate crown of the Sun-god as the symbol of their divinity;

while on the reverses appears the eagle, the symbol of the soul flown heavenwards, the pyre, the temple, or types of "Aeternitas," that world beyond time, conceived of as in the starry heavens, to which the soul of the good depart.

Diocletian.—Diocletian refounded the Roman Empire, but in a form that Augustus would hardly have recognized. The Emperor is now a monarch of the Eastern pattern, even in his lifetime receiving something like divine worship.

The mints formed a section of the department of the chancellor of the exchequer and, under him, were administered by "rationales." The moneyers, like so many other professions of the age of Diocletian, were organized as a rigid caste, from which escape was barely possible. They were subject to severe discipline and terrible penalties for abuses: but, despite this, false coinage was immensely prevalent and flourished in the face of repression.

Diocletian in A.D. 296 completed the task which Aurelian had begun. He finally cleared away the depreciated coinages of the 3rd century and issued a new coinage, based on sound gold and silver coins. His gold piece was struck at sixty to the pound of gold, his silver at ninety-six to the pound of silver. His successors continued his policy in the main lines unchanged. Constantine substituted the *solidus*, a piece of $\frac{1}{2}$ nd of the pound, for Diocletian's sixtieth; this standard found general acceptance and passed on to the famous "besant" of the Byzantine Empire. In the first thirty-five years of the 4th century silver was very sparingly struck. When its free issue was resumed, new denominations, the *milliarese* ($\frac{1}{1,000}$ of the gold pound) and *siliqua* ($\frac{1}{1,792}$ of the gold pound) soon replaced Diocletian's ninety-sixth. The silver came more and more to be struck below standard weight—that is to say, to become a subordinate token coinage. The basis of the system was the steady supply of a standard gold coin.

Whether Diocletian and his successors issued a regular coinage in bronze or copper is very doubtful. They certainly continued to issue the very base billon, which represented the last stage of the debasement of the double denarius.

Diocletian's reform must have brought some improvement on the chaos of the great anarchy of the third century. But one great evil persisted—the cost of living remained high and would not come down. Diocletian's edict of A.D. 301 fixing maximum prices, was undoubtedly only one of a series of blows aimed at a recurrent social evil.

Influence of Christianity.—The spirit of the coinage undergoes a change, similar to that of its form. The divine Emperor dominates the entire coinage: even the gods hardly appear except as patrons of the new dynasty—Jupiter for Diocletian, Hercules for Maximian, Mars for Galerius, Sol for Constantius I. When Christianity, surviving the great persecution, received full tolerance and increasingly marked favours from Constantine, the pagan element in the coinage declined. Little of Christianity, however, took its place. For many years types and legends of a neutral character were preferred, though Christian signs and emblems—cross, monogram of Jesus Christ, *labarum* (Christian standard) begin to appear. There was in fact an unavowed truce between old and new. After Julian—who revived pagan types on his coins—notably the Apis bull of Egypt—the Christian element becomes stronger. The Emperor appears more and more as the defender of the faith, the imperial Victory shades off into the Christian angel. But the full development of the Christian tradition in coinage was reserved for Byzantium.

The Roman coinage of the East passes on without interruption into that of Byzantium. In the West, the Empire, succumbing to the barbarians in the late 5th century, left them its coinage as part of its legacy.

MEDIAEVAL AND LATER EUROPEAN COINS

With the fall of the Western empire, the coinage of the Byzantine empire became the great influence in European currency. The Byzantine period in coinage may be considered to begin in the reign of Anastasius. The coins are in the three metals, but the silver is rare, and was probably struck in small quantities. At first the gold and silver are fine, but, towards the close of the

empire, much alloyed. The gold coin is the *solidus* of Constantine (Pl. II.-19), with its half and its third (*semissis* and *tremissis*). The Byzantine *solidus* (*besant*) (Pl. II.-21) throughout the middle ages was the gold coin of European trade until the introduction of Italian gold in the 13th century. The chief silver coin was the *milliaris*, and a smaller coin, the *siliqua* or *keration*.

In 498 Anastasius introduced a new copper coinage, bearing on the reverse, the following marks of value in place of a type: M, K, I and E, 40 *nummi*, 20, 10 and 5. These coins bear beneath the values the abbreviated name of the place of issue. Justinian I. added the regnal year in A.D. 538, his twelfth year; this is the first appearance of annual dating on European coinage. The money of this class shows extraordinary variations of weight, which reflect the state of the imperial finances. Under Basil I. the bronze money to all appearances was reformed, but the absence of marks of value makes the whole later history of the coinage in this metal very difficult. There was one curious change in the shape of the money. Early in the eleventh century the *solidus* begins to assume a cup-shaped form, and this subsequently became the shape of the whole coinage except the smaller bronze pieces. These coins are called *nummi scyphati*. The types, except when they refer simply to the sovereign, are of a religious and Christian character.

On the reverse of the oldest coins we have such types as a Victory holding a cross (other personifications all but disappear), but on those of later ones a representation of Christ or the Virgin Mary. Christ first appears on a coin of about A.D. 450, where He is represented marrying Pulcheria to Marcian. He does not appear again until the end of the 7th century, when His bust is introduced by Justinian II. From the 9th century Christ appears in various forms on the coins; about 900 we find the Virgin; a few years later saints, St. George, St. Michael, St. Theodore, etc., begin to appear. A remarkable type was introduced by Michael VIII. Palaeologus, who recovered Constantinople from the Latins in 1261, and issued coins with the Virgin standing in the midst of the walls of the city. Another notable type is the adoration of the Magi. The principal inscriptions for a long period almost invariably relate to the sovereign, and give his name and titles. The secondary inscriptions of the earlier coins indicate the town at which the piece was struck, and in the case of the larger bronze pieces, the year of the Emperor's reign is given. From about the 10th century there are generally two principal inscriptions, the one relating to the emperor and the other to the sacred figure of the reverse, in the form of a prayer. The secondary inscriptions at the same time are descriptive, and are merely abbreviations of the names or titles of the sacred personages beside the representations of whom they are placed. From the time of Alexius I. (Comnenus) the principal inscriptions practically disappear, and descriptive ones alone are given. These are nearly always abbreviations, like the secondary ones of the earlier period. The language of the inscriptions was at first Latin with a partial use of Greek; about the time of Heraclius Greek began to take its place on a rude class of coins, probably local; in the 8th century *Basileus* and *despotes* replace *Augustus*; by the 9th century Greek inscriptions occur in the regular coinage; and by the time of Alexius I. Latin has wholly disappeared. The Greek inscriptions are remarkable for their orthography, which indicates the changes of the language. In the 11th century we have a few metrical inscriptions, a practice commoner in Asia than in Europe. From the time of Justinian (6th century) onwards the profile which has been usual for centuries practically disappears from the coinage, and is replaced by a facing bust. The last Byzantine gold coin (a piece of John V., 1341-91) shows a figure of John the Baptist imitated from the Florentine coinage.

Cognate Groups.—Besides the regular series of the Byzantine empire, there are several groups connected with it, either because of their similarity, or because the sovereigns were of the imperial houses. These are the coinages of various barbarians, and the money of the emperors of Niceaea, of Thessalonica, and of Trebizond (Pl. III.-2, 3). The last groups consist of small silver pieces, which were prized for their purity; they were called *Comnenian white-money* (*δραμα κομνηνα*), the princes of Trebizond hav-

ing sprung from the illustrious family of the Comneni.

The coinage of the other states of the West falls into well-defined periods which have been distinguished as (1) transitional period, from Roman to true mediaeval coinage, *i.e.*, from the fall of Rome (476) to the accession of Charlemagne (768); (2) true mediaeval period, during which Carolingian money was the currency of Western Europe; this covers the period from Charlemagne to the end of the Swabian house in 1286; (3) early Renaissance from the first issue of the florin at Florence in 1252 to the beginning of the classical Renaissance in the middle of the 15th century; (4) the Renaissance and (5) modern period.

Mediaeval.—The main feature of the mediaeval period is the disappearance of gold and rise of silver and the return of gold from the 15th century onwards. The inconvenience of gold money when it represents a very large value in the necessities of life must have caused its abandonment and the substitution of silver by the Carolingians. The denier (denarius) or penny of about 24 grains was at first practically the sole coin. The solidus in gold was struck but very rarely, perhaps as a kind of proof of the right of coining. The Byzantine solidus or bezant was used and probably the equivalent Arab gold. The new coinage spread from France, where it was first royal and then royal and feudal, to Germany, Italy, where the Byzantine types did not wholly disappear, England, Scandinavia, Castile and Aragon. In Germany and France feudal money was soon issued, and in Italy towns and ecclesiastical foundations largely acquired from the empire the right of coinage, which was elsewhere rare. The consequence of the extended right of coinage was a depreciation in weight, and in the middle of the 12th century the one-sided deniers called *bracteates* appeared in Germany, which were so thin that they could only be stamped on one side. The types of this whole second coinage are new, except when the bust of the emperor is engraved. The most usual are the cross; and the church as a temple also appears, ultimately taking the form of a Gothic building. There are also sacred figures, and more rarely busts in the later age.

The great precursor of the Renaissance was the emperor Frederick II. (1215–50). In his restoration of the gold coinage he had already been preceded by the Norman Duke of Apulia, who for the convenience of these Arab subjects and for commercial reasons also had continued the gold coinage of the Fatimids, the great currency at that time of all the western Muslims. Roger II. (1130–54) also struck Latin coins of his own as DVX APVLIAE, the first ducats. Frederick II., continuing the gold standard, also struck his own Roman gold money, solidi and half solidi, with his bust as emperor of the Romans, Caesar Augustus, and on the reverse the imperial eagle, in keeping with the obverse title. In workmanship these were the finest coins produced in the middle ages. It is not till the great Swabian that we get the final establishment of a worthy coinage, a necessity of their large commercial schemes. The famous gold florin was first issued in 1252 and at once became popular. The obverse type is the standing figure of St. John the Baptist, the reverse bears the lily of Florence. The weight was about 54 grains, but the breadth of the coin and the beauty of the work gave it dignity. The commercial greatness of Florence and the purity of the florin caused the issue of smaller coins in almost all parts of Europe. Venice was not long in striking (in 1248) a gold coin of the same weight as the florin, but with the types of a standing figure of Christ, and the doge receiving the gonfalon at the hands of St. Mark, a type suggested by Byzantium. It was first called the ducat, the name it always bears in its inscription; later it is known as the *zecchino* or *sequin*. Though not so largely imitated in type as the florin, the extreme purity of the sequin made it a world currency down to the 19th century. Genoa likewise had a great gold currency, and the other Italian states struck in this metal. Many varieties of gold money appear in course of time in France, England and to a less extent in other countries. The need for heavier silver coinage caused the issue of the large denier (*grossus denarius*, *gros* or *groat*). This coin appears early in the 14th century. The types from the 14th century onwards are many and distinctly worthy of the art of the time, which as yet is purely decorative and conventional, so that portraits are not possible. The religious inten-

tion also is gradually giving way to the desire to produce a beautiful result, and the symbol of the cross is varied to suit the decorative needs of the coin. Heraldic subjects also appear, and in the shield, which is frequently a reverse type, we see the origin of the usual modern reverse of the most important coins.

With the classical Renaissance we find ourselves in the presence of modern ideas. It is a period of innumerable small states and kingdoms with no uniformity of coinage yet most modern series can be traced back to it. Its most remarkable characteristic is the revival of portraiture and from the 16th century with the opening of the new world the enormous increase in output of coins in gold and silver. With the institution of the German thaler in 1518, it speedily became the chief European piece in its metal, and to its popularity is no doubt due the large silver pieces of other countries—crowns, ecus and scudos.

In the west a number of coins carry on the Roman tradition. They cover the period from the 5th to the 8th centuries, and are of considerable historical significance. The types throughout are monotonous: the bust of a Roman emperor or local ruler, a cross of some kind, a Victory, etc. The style is quite barbarous. The classification of the earliest servile imitations of Roman and Byzantine money rests only on origin and is uncertain. The following general series are distinguished: (A) The Vandals (Pl. III.-1) (Africa, 428–534) issued gold (?), silver and bronze from Huneric (477–84) to Gelamir (530–34); the gold is anonymous. (B) The Suevians (Spain, 409–585) had little but imitations of Byzantine gold; but Richiar (448–456) issued a denarius in his own name. (C) The Ostrogoths (Italy, 489–553) were preceded by the Herulian Odoacer (476–94), who coined silver and bronze; their kings (including Theodoric, 493–526, and Totila or Badulla, 541–52) issued gold, silver and bronze in their own names, from Rome, Ravenna, Milan, etc. (D) The Lombards (Italy, 568–774) had no coins in their own names before Grimoald, duke of Beneventum (662–71); later there are gold solidi and thirds and silver from many mints. Gold was issued for the duchy of Beneventum in the 8th century. (E) The Burgundians (Gaul, to 534) first issued recognizable coins under Gondebald (473–516). (F) The Visigoths (South Gaul and Spain) had imitative gold thirds in the 5th and 6th centuries; the kings' names appear from Leovigild (573–586) to Roderic (710–11). Sixty-one mints were in operation. (G) The Meroving Franks first issued under Clovis I. (481–511) coins recognizably Frankish (solidi and thirds). Royal names first appear on silver and copper under Theoderic of Austrasia (511–34) and Childebert I. of Paris (511–58). The chief Frankish inscribed coinage is, however, of gold solidi and thirds, from Theodebert I. (534–48), who broke down the Roman imperial prerogative and issued gold with his own name in full, to the beginning of the 8th century. The last Merovingians issued no coins in their own names, being mere puppets. From the middle of the 6th century the coins with kings' names are far less numerous than those bearing the names only of mints and moneyers; some 800 places (not only in what is now France, but in Germany, the Low Countries and Switzerland) are thus named. This coinage seems to have been intimately connected with the fiscal organization, though the generally accepted theory that the taxes collected in each place were there and then converted into money is by no means proved. Certain religious establishments also possessed the right of coining in their own name. The close of the Merovingian dynasty saw a revival of silver in the *saiga*, which heralded the introduction of the denier. (H) In England the Anglo-Saxons began with an imitative coinage similar to the Merovingian, *viz.*, gold, *solidi* and *thirds*, and silver *sceattas* of about 20 grains troy, and *stycas*, first of silver, then of copper. The gold is rare and confined to the south; only two *solidi* are known, imitations of Honorius, with Runic legends on the reverse.

Portugal.—The coinages of the various countries of Europe from the end of Roman coinage and its imitations can be briefly mentioned in geographical order from west to east. The money of Portugal begins, after the expulsion of the Moors, with Alphonso I. (1112); it is exclusively regal, and not of great interest except as affording indications of the wealth and commercial activity of the state in the early part of the 12th century.

The early golds are of interest as by the arrangement of their type and inscription they try to look as like Moorish coins as possible.

Spain.—The coinage of Spain, after the reconquest from the Moors, is almost without exception regal. The Kingdom of Navarre had a coinage from the time of Sancho III. (1000-35). The series of Castile and Leon begins with Alphonso VI. (1053) with deniers and obols. Aragon first has coins under Sancho Ramirez I. (1063). Gold (as in Portugal imitated from Moorish money) is introduced in the middle of the 12th century. A plentiful coinage was issued after the union of the crowns in 1479. The Spanish dollar of the 17th and 18th centuries was one of the most widely circulating currencies in the West.

France.—In France in 755 Pepin the Short abolished the gold coinage of his Merovingian predecessors and introduced the silver denier (denarius = penny); the coinage became a royal prerogative once more and confined to a few mints. The denier (Pl. III.-6), which at first weighed c. 1.28 gramme (19½ grains), was for centuries the chief of European silver coins. Under Charlemagne the weight was slightly raised; the Caroline monogram appears and there are other modifications in the types. Charlemagne also issued money from various Italian, German and Spanish mints. He also introduced the obol, and struck gold (chiefly at Italian mints). Among his types must be noted the temple with the inscription *XPISTIANA RELIGIO*. Louis le Debonnaire (814-840) was the last Carolingian to strike gold. In the 9th century are perceptible the first traces of the movement which led to the extensive feudal coinage. The advent of the house of Capet made no great change in the system, but the feudal issues now become important. The most widespread denier was that of the abbey of St. Martin at Tours (*denier tournois*); the royal coinage was known as the *monnaie parisienne*. Louis IX. (1226-70) effected a great reform late in his reign, making the sou (hitherto a money of account) into a real coin as the *gros* and introducing a gold coinage. Henceforward the coinage increases in complexity; in the 14th century it has great artistic merit, especially the gold; from the end of the 16th century it becomes conventional.

Belgium.—Passing on to Belgium, its coinage, which, except for the few mints operating under the Merovingians and Carolingians, does not begin until the 11th century, comprises many pieces struck by foreign rulers, and has little of an independent character in either the regal or the seigniorial class. The most important coinages are those of the house of Burgundy and Charles V. and his son, and of the bishops of Liège. The coinage of Belgium approaches the French on the one side, the German on the other.

Switzerland.—The multitudinous coinage of Switzerland illustrates the varying fortunes of this central state, and its gradual growth and consolidation. First we have the gold money of the Frankish kings, among whose mints Basel, Lausanne, St. Maurice-Valais and Sitten (Sion) already appear. The silver deniers, which Charlemagne made the coinage of the empire, are issued by fewer mints; the dukes of Swabia began to strike at Zürich in the 10th century, and the empire granted during the 10th and down to the 13th century the right of coinage to various ecclesiastical foundations, bishoprics and abbeys. Bern was allowed a mint by the emperor Frederick II. in 1218, and other towns and seigneurs subsequently gained the same right. The demi-bracteate appears about the middle of the 11th century, and about 1125 is superseded by the true bracteate, which lasts until about 1300. The 14th century witnessed the rise of the Swiss confederation, and by degrees the cantons struck their own money. These, together with the coins of some few sees and abbeys, form the bulk of Swiss money of the mediæval and modern periods. The separate cantonal coinage, interrupted by the French occupation, was finally suppressed in 1848, when a uniform currency was adopted.

Italy.—Italy, with Sicily, has special features. Here the barbaric coinages were mixed with the Byzantine issues which marked the recovery of the Eastern empire, and left a lasting influence in the north at Venice, and in the south at Beneventum. Later the Arab occupation of Sicily and the predominance of Arab coins left their mark in the curious Oriental coinages with Arabic inscriptions of the Normans of Sicily and of the Emperor Frederick II., mixed after his fashion with Latin coinage. The earliest

money is that of the barbarian Ostrogoths and Lombards, and local Byzantine issues in Sicily. This is followed by the deniers of Charlemagne and his successors, succeeded by the gold currencies of the Normans and Frederick II. The age of the free cities is marked by the great coinages of Florence, Venice and Genoa, while the Angevin and Aragonese princes coined in the south, and the popes began to issue a regular currency of their own at Rome. The Italian princes of the next period coined in Savoy, and at Florence, Modena, Mantua and other cities, while Rome and the foreign rulers of the south continued their mintages. Venice and Genoa of the republics alone surviving.

The money of Florence, as may be observed, is disappointing in its art, for the great commercial currencies have to be conservative. The silver florin was first struck in 1189. It is heavier than the denier, weighing about 27 grains, and bears the lily of Florence and the bust of St. John the Baptist. These are thenceforward the leading types, the flower never changing, but the representation of the saint being varied. On the gold florin, first issued in 1252, the Baptist is represented standing, while in the contemporary silver florins he is seated. The latter have a rhyming legend, "*Det tibi florere Christus, Florentia vere.*"

Venice as a mint rivals Florence in conservatism, and the early style is distinctly Byzantine; commercial reasons had to prevail in keeping coin types unchanged even in a great artistic city. The famous Venetian *zechino* or *sequin*, the rival of the florin of Florence, appears to have been first issued under Giovanni Dandolo (1284). On the obverse St. Mark gives the gonfalon to the kneeling doge, and on the reverse is a standing figure of the Saviour within an oval nimbus and a rhyming legend, "*Sit tibi, Christe, datus Quem tu regis, iste ductus.*"

The series of the coins of Rome is rather of historical than of artistic merit. The popes begin to strike money under Adrian I. (A.D. 772-795), whose deniers are in a Byzantino-Lombard style. The coins of his successors, excepting few, down to Leo IX. (1049) associate the names of pope and emperor (Pl. III.-5). From Leo IX. to Urban V. (1362) there is no papal coinage. The Roman senate strikes from 1188 onwards. We then see on the silver the style of the senate and Roman people, and *ROMA CAPUT MUNDI*. Some coins have the figures of St. Paul and St. Peter, others Rome seated and a lion. Charles of Anjou, King of Sicily (1263-85), strikes as a senator, and Cola di Rienzo (1347-48) as tribune. The gold ducat of about 1300 imitates the types of the Venetian sequin. St. Peter here gives the gonfalon to a kneeling senator. The arms of the moneying senator next appear in the field. The papal coinage is resumed at Avignon; and Urban V., on his return to Rome, takes the sole right of the mint. From Martin V. (1417) to Pius IX. there is a continuous papal coinage. The later coins, though they have an interest from their bearing on the history of art, are disappointing in style (Pl. III.-10). We have beautiful gold coins of Giovanni Bentivoglio, lord of Bologna, who employed Francia at his mint, and we know that the artist remained at his post after Julius II. had taken the city. There are also pieces of Clement VII. by Cellini, vigorous in design but careless in execution. There were papal mints at Ancona, Bologna, Piacenza, Parma, Ferrara and other Italian towns; and coins were also struck at Avignon from 1342 to 1700. When the City of the Vatican state was created in 1929 it was accorded the right of issuing its own coinage.

The coinage of Sicily, afterwards that of the Two Sicilies, or Naples and Sicily, begins with the Normans. Theirs is a curiously mixed series. It begins with Robert Guiscard as duke of Apulia (1075) and Roger I. of Sicily (1072). The gold money is almost wholly Arabic though Roger II. struck the Latin ducat, the earliest of its class; the silver is Arabic, except the great Latin scyphati of Roger II. with Roger III.; the copper is Latin (Pl. III.-4) and Arabic. The gold series (*Augustales*) of the emperor Frederick II. (1198-1250) shows the first sentiment of reviving classical art, its work far in advance of the age. These are Latin coins; he also struck small Arabic pieces in gold. Under Conrad and Manfred there is little coinage, copper only, but with Charles I. (Pl. III.-9) of Anjou (1266-85) the gold money in purely mediæval style is beautiful, quite equal to that of his brother, St. Louis of France.

After this time there is a great issue of *gigliati*, silver coins with, for reverse, a cross fleurdelysée cantoned with fleur-de-lis (Pl. III.-7).

Germany.—The money of Germany, with which we include Austria and Hungary is, like that of Italy, far too varied for it to be possible here to do more than sketch some of its main features. In the Frankish period mints were in operation at cities in the west, such as Mainz, Strassburg, Speyer, Treves, Worms, Cologne. Pepin issued denarii from Strassburg and Mainz; under his successors denarii and obols were also coined at other mints, as Bonn, Cologne, Spire, Treves. After the reign of Louis the Child (910–11) the Carolingian system was continued until the advent of the Swabians with Conrad III. (1138–52). In the succeeding period which ends with the introduction of the *grossus* and the gold coinage under Louis of Bavaria (1314–47), the uniformity of the currency disappears. In the west (in Lotharingia, including the southern Low Countries, the Moselle and Rhine-lands, in Frisia, Bavaria, parts of Franconia and Swabia) the *denier* continues; but elsewhere we find the *bracteate*. The right of coinage is acquired in an increasing measure by the feudatories of the empire. With the introduction of the regular gold coinage (consisting for the most part of florins) and the *grossus* in the 14th century, Germany enters on the modern period. From the 16th century the *thaler* (so called from Joachimsthal in Bohemia, where the counts of Schlick first struck the coin in 1518) dominates the silver currency. The *thalers* and other large coins of the 16th and 17th centuries are often good and always vigorous in workmanship. By the convention of 1857 the *thaler* was recognized as the unit for Berlin and the north, the florin of 100 *kreuzers* for Austria, the florin of 60 *kr.* for the south. A uniform system, based on the gold *reichsmark* of 100 *pfennigs*, was established all over the German empire in 1876. Of particular currencies in Germany we must be content with the mention of some of the more important. Among the great rulers we note the dukes of Bavaria, who coined from Henry I. (948–55), and issued fine *thalers* in the 16th century. The Counts Palatine of the Rhine coined from 1294, their mints being at Heidelberg, Frankfurt, etc. The Saxon coinage begins with Duke Bernard (973) and includes a large series of *bracteates* and *thalers*, the latter being especially famous. The Brunswick coinage begins in the 11th century; besides its *bracteates* we note the large mining-*thalers* of the 16th and 17th centuries (up to ten *thaler*-pieces). There are good *bracteates* and *thalers* of the margraves of Brandenburg; from 1701 they coin as kings of Prussia. In Austria there is a ducal coinage from the 12th century; the gold florin of Florentine character appears under Albert II. (1330–1358). The marriage-coin of Maximilian and Maria of Burgundy (a 16th-century reproduction of a medal made by the Italian, Candida in 1479) is a striking piece, and in the 16th century there is a large series of fine *thalers*. The *thalers* of Maria Theresa became popular on either side of the Red Sea, and those of the date 1780 are still recoined for trade there. In Bohemia there is a ducal coinage from the early 10th century to 1192; then came the regal *bracteates*. Wenceslas II. (1278–1305) struck the first German *grossus* at Prague. The gold florin made its appearance under John of Luxemburg (1310–47). In Hungary the regal coinage begins with St. Stephen (1000). Charles I. of Anjou (1310–42) introduced the florin and *grossus*. Of historical interest is the money of John Hunyadi as regent (1441–52). The abundance of gold about this time and later shows the metallic wealth of the land. The same is true of the rich gold coinage of the Transylvanian princes in the 16th and 17th centuries. Of ecclesiastical coinages the most important are at Münster, Cologne, Mainz, Treves, Augsburg, Magdeburg, Spire, Würzburg, Salaburg. The Cologne series of coins is almost continuous from the Frankish period; the archbishops first received the right from Otto I., Brune (953–65) being the first to coin; from Pilgrim (1021–36) the series, issued at various mints in the Rhineland, is very complete down to 1802. The series of Treves ranges from Theodoric I. (965–75) to Clement Wenceslas (1794). The archiepiscopal coinage of Mainz begins with Willigis (975) and lasts until 1802; its mints included Erfurt, Bingen and many other places. The Salzburg series (beginning 996) is re-

markable for its fine *thalers* (especially of Mathias Lang, 1519–1540). The patriarchs of Aquileia, who may be mentioned here, acquired the right of coinage from Louis II. in the 9th century, but the first who can be identified on the coins is Godfrey (1184); thence onwards there is an interesting series of denarii and smaller coins down to the early 15th century. Of cities with large coinages it is sufficient to mention Aix-la-Chapelle (from the time of Frederick I. to 1795), Frankfurt-on-the-Main, Hamburg (with great gold pieces of the 16th and 17th centuries, up to 10 ducats) and Nuremberg.

Scandinavian Countries.—The origin of the coinage of the Scandinavian states: Norway, Denmark and Sweden, is clearly English and due to the Danish conquest of England. The Runic alphabet is employed, though not by any means exclusively, on many of the early coins of Denmark and Norway. The Norwegian series begins with Hakon Jarl (989–96), who copies the pennies of Aethelred II. In the second half of the 11th century begins a coinage of small, thin pennies, which develop into *bracteates*. Magnus IV. (1263–80) restores the coinage, more or less imitating the English *sterlings* of the time. Norway and Denmark were united under Eric of Pomerania in 1396. The money of Denmark begins with pennies of Sweyn (985–1014) which are copied from the coinage of Aethelred II.; the coins of Canute the Great (1014–1035) and Hardicanute (1036–42) are mainly English in character. With Magnus (1042–47) other influences, especially Byzantine, appear, and the latter is very strong under Sweyn Aestriðson (1047–76). *Bracteates* come in in the second half of the 12th century. The coinage is very difficult of classification until the time of Eric of Pomerania (1396). There are important episcopal coinages at Roskilde and Lund in the 12th and 13th centuries. Sweden has very few early coins, beginning with imitations of Olaf Skötkonug (995) of English pennies and showing the usual *bracteate* coinage. The money was restored by Albert of Mecklenburg (1363–87). The *thaler* is introduced by Sten Sture the younger (1512–20). The money of Gustavus Adolphus is historically interesting. Under Charles XII. there is highly curious money of necessity. The daler is struck as a small copper coin, sometimes plated. The types include the Roman divinities. At the same time and later there was a large issue of enormous plates of copper, stamped with their full value in silver money as a countermark.

Russia.—The earliest Russian coinage begins with the princes of Kiev as early as the end of the 10th century; it shows strong Byzantine influence. The grand princes from the early 15th century struck curious little silver pieces. The coinage was modernized by Peter the Great, who introduced a regular gold coinage. The large silver and copper coins of his successors are very plentiful. Nicholas I. (1825–55) introduced a platinum coinage of about two-fifths the value of gold.

Other Countries.—The Christian coinages of the northern Balkan States are of great morphological interest. They are chiefly silver *grossi*, showing a mixture of Byzantine and Venetian influences. The Bulgarians had a regular silver coinage from Asien I. (1186–96) to John Sismania (1371–95). The Serbian coinage lasts from Vladislav I. (1234–40) to the middle of the 15th century. There is also a coinage of the Bans of Bosnia (late 13th to 15th century). The modern coinages of the Balkan States are of the 19th century only. The independent city of Ragusa is remarkable for the bold style of its early copper (13th century, inspired by Roman models of the 4th century) and the richness and variety of its later issues.

BRITISH COINS

The earliest coins struck in Britain were rude uninscribed imitations of the stater of Philip II. of Macedon (359–336 B.C.), one of the great currencies of the ancient world; they reached Britain through Gaul where they had been imitated by the various tribes there (Pl. IV.-1). The exact distribution of the earliest coins of this type found in Britain between British and Gaulish mints is still uncertain. These coins are of gold of gradually diminishing purity and are at first uninscribed. Under Roman influence we have the introduction of silver and copper coins towards the end

of the last century B.C.; inscriptions also now appear on the coins so that we can identify the coinage of Tincommius and Cunobelinus (Cymbeline) (Pl. IV.-2) and others known and unknown to history. With the Roman conquest native coinage disappears and if we except the Roman coins from the mint of London in the 3rd and 4th centuries A.D., we have no British coinage again till the departure of the Romans. Gradually degenerating copies of Roman types formed the currency of Britain from the 5th to the 7th century, when we are once more able to attribute the coins to definite rulers. In the 7th century we have the extensive coinage of little silver pieces known as "sceats" with a considerable variety of types and legends in Runic letters, which enable some to be attributed, for example to Peada, king of Mercia, (655-57 A.D.). About the same time in the kingdom of Northumbria we have the small copper coins known as "stycas" (Pl. IV.-3), which record a long series of kings from Egfrith (670-85) onwards. But it is from the reign of Offa (757-96) who introduced the silver "penny" that English coinage may be said to date. In its broad flat fabric, contrasted with the thick fabric of its predecessors, it shows the influence of its Carolingian prototype but the designs are thoroughly Anglo-Saxon and the portrait of Offa (Pl. IV.-4), a remarkable piece of work, reaches a level not equalled again in English coinage till the reign of Henry VII. The inscriptions, obverse name of the king and reverse that of the moneyer, were to remain unchanged in form till the reign of Edward I.; for the same period also the silver penny was the only English coin. A remarkable coin struck by Offa is his imitation of an Arab dinar of the Caliph al-Mansûr with the additional legend OFFA REX, one of the few and exceptional gold coins of the Anglo-Saxon period. About the same time we find the Archbishops of Canterbury beginning to issue coins, the earliest being those of Jaenberht (766-90) bearing the names of the suzerain Offa also. The kings of Kent and the kings of East Anglia also began to strike pennies: the rise of Wessex after the battle of Ellandune in 825 can be traced in the coinage; the earliest coins of Wessex were those struck at Canterbury by Egberht and his conquest of Kent, and the mints of Alfred's reign (Pl. IV.-5) reveal how West Saxon power had expanded. The Danish invaders have also left extensive numismatic records, some of exceptional historical interest like the London coinage of Halfdan. The troubled state of the country is reflected in the many barbarous and hurriedly struck coins of this period. The peace and prosperity which returned after the peace of Wedmore (873) is seen in the improved workmanship of the coinage, with a more careful treatment of the portrait and a great variety of original work in the reverse types, a feature which was not long maintained. In the 10th century it became the regular practice to add the name of the mint as well as that of the moneyer on the reverse. In the edicts of the Council of Greatley (928) we have the earliest surviving mint ordinances. Coins were only to be struck at certain towns and each town was to have only one moneyer with certain specified exceptions (e.g., 8 for London). The number of mints increased till in the reign of Aethelred II. we have over seventy; from about his time also the king's portrait, which had only been occasionally used, became the regular obverse type on the coinage, while the reverse type also became stereotyped to some form of cross (Pl. IV.-6).

The Norman conquest made no change in the coinage or mint system and we even find that pre-conquest moneyers stayed in office and struck coins for William I. (Pl. IV.-7). But the coin-types were now regularly changed partly as a source of revenue, for the moneyers had to make a payment when new dies were issued, partly as a check on forgery. The dies were made in London and sent to the country mints. The pennies of William II. have nothing in their legend to distinguish them from his father's issues but students have been able to allot eight types to William I. and five to his son. Forgers gave Henry I. much trouble and one step he took to prevent it was to issue his later coins with a snick in the edge to show that the silver was good. The civil wars of Stephen's reign produced many interesting coins such as those struck in Matilda's name and the pennies of Eustace Fitzjohn and other barons.

Henry II. ceased the practice of regularly changing the types which had been the custom since William I.'s reign and struck one type till 1180. In this type the work of the English mints reached its lowest level; the coins frequently have only a letter or two of the legends and fragments of the type. His second type the "short-cross," so called from its reverse design, first issued in 1180, remained unchanged—including the name *Henricus*—not only by Henry II. but also by Richard and John and Henry III. till 1247. In 1247 Henry III. coined the "long-cross" penny with the arms of the cross extended to the edge of the coin with a view to preventing clipping. He also reduced considerably the number of mints. In 1279 Edward I. introduced a new type of penny obv.: bust of the king and reverse: long cross with three pellets in each angle, a type which was much imitated abroad and persisted in the silver coinage till the reign of Henry VII. The moneyer's name disappeared from the reverse legend and its place was taken by the name of the mint CIVITAS LONDON, etc. He also struck halfpennies and farthings to replace the cut pennies which had hitherto done duty for small change. He also introduced a groat or fourpenny piece (Pl. IV.-9) (groat = *gros* = *grossus*, large *denarius*-penny) but the time was not yet ripe for this larger coin and it did not establish itself till Edward III.'s reign. The coins of Edward I., II., III. cannot be distinguished by their legends; a minute study of them has, however, enabled them to be attributed satisfactorily.

Henry III. had attempted to issue a gold coinage by striking the gold penny (Pl. IV.-8) of the value of 20 pence silver, later raised to 24, but the difficulty of rating gold to silver proved insuperable and the coinage was withdrawn. In 1344 Edward III. with the issue of his fine series, the florin, leopard, and helm ($\frac{1}{2}$ and $\frac{1}{4}$ florin) again attempted without success to introduce a gold currency: the attempt was renewed with the noble and after various experiments with its weights a gold coinage was finally established in currency in 1351 with a noble of 120 grains of gold and its subdivision the half and quarter noble. The silver penny was reduced to 18 grains and the groat first issued in the same year. The noble (Pl. VII.-4) was valued at 6s. 8d. The obverse type of the noble, the king in a ship, is supposed to allude to the naval victory of Sluys. The reverse type is a floreate cross with considerable ornamentation. Edward IV. distinguished his noble by a rose on the ship (rose-noble or ryal) and raised its value to 10s., while a new gold coin, the "angel," was introduced to replace the old value of the noble at 6s. 8d.; the penny was reduced to 12 gr.

The angel (Pl. VII.-8) is so called from its type of St. Michael and Lucifer. The reverse is a ship with a cross in front of the mast. The angel in the 16th century became the piece given to those touched for king's evil; it was struck for this purpose down to the reign of Charles I.; it was not again issued as legal tender but small copies of it were struck by the later Stuarts and pretenders for presentation at the ceremony of touching for king's evil. The next important change in the coinage was not till the reign of Henry VII. This was the introduction of the sovereign (Pl. VII.-11), a large gold coin of 240 grains current for 20s.; the obverse type was the king seated in an elaborate throne and the reverse a Tudor rose with a shield of arms in the centre. The same ruler also issued the first English shilling or testoon, a handsome coin with a fine portrait, in 1583, but this did not attain much currency. Henry VIII. altered the types of the smaller silver coins by replacing the three centuries old cross and pellets by a long cross and shield while the inscription POSUI DEUM ADJUTOREM MEUM took the place of the mint legend; the stereotyped bust was replaced by an excellent profile portrait on the groat and the seated king on the penny: Henry VIII. debased the gold and reduced the weight of the sovereign, the reverse type of which was now the royal arms supported by a lion and dragon. He introduced the gold crown of 5s. and half-crown and raised the angel to 7s. 6d., introducing the George noble to take its old value of 6s. 8d.—so called from its type of St. George and Dragon (Pl. IV.-10). In 1544 he issued the base shilling or testoon of 12 pence and debased the silver coinage. It was in his reign that the archiepiscopal mints of Canterbury, York and Dur-

ANCIENT AND MODERN ORIENTAL COINS

1-13. INDIAN. 1. Tetradrachm of Menander. Graeco-Indian, c. 2nd-1st century B.C. 2. Stater of Kanishka. 3. Punch-marked, c. 3rd century B.C. 4. Western satrap. Silver, 1st century B.C.-4th century A.D. 5. Samudragupta, 4th century. 6. Samantadeva. 7. Govindechandra. 8. Chera, mediaeval. 9. Massa of Ceylon, c. 1200. 10, 11. Mahmud of Ghazna, 11th and 12th century. 12. Sher Shah rupee. 13. Mohur (gold) of Akbar. 14. ANNAM. 15-17. CHINESE. 15. Five-chu piece (copper), c. A.D. 500-550. 16. Kai Yuan, A.D. 618-627. 17. Hsien Feng, struck for Chinese Turkistan. 20. Republic. 18-19. 21. JAPANESE. 18. 2 bu piece (gold). 19. Sen. 21. Modern gold 10-yen piece

ham were abolished, the former having exercised its privilege for nearly eight centuries. When Edward VI. again restored a coinage of fine silver he introduced the silver crown of five shillings, which took the name of the gold piece of the same value introduced a few years earlier. The reign of Mary is notable for the appearance of her husband Philip II. of Spain on the shilling.

Elizabeth continued her father's denominations and restored the purity of the silver coinage. By introducing the sixpence and threepence of silver she gave the groat its deathblow, although it and the twopence continued to be struck. She also introduced coinage by machinery (mill and screw) although it was not really established until after the Restoration. James I. introduced a number of new gold coins, the most important being the "unite" or sovereign (20s.), so called from its legend (*Paciam eos in gentem unam*) alluding to the union of the crowns. In his reign the number of denominations in use reached its maximum. Charles I. (Pl. IV.-2) made no changes in the coinage of the last years of his father, but the Civil War and the king's financial difficulties added many new coins to the English series. These were 20s. and 10s. pieces in silver and the large gold pieces, e.g., £3 pieces of Oxford and Shrewsbury, the fine Oxford silver crown by Rawlins with a view of Oxford behind the usual type of the king on horseback; the siege pieces rudely struck on pieces of silver plate at various Royalist strongholds show to what straits the king's party was reduced (Pl. IV.-13). Under James I. and Charles I. we have the first English copper coins, the "Harrington" farthings; they were not struck by the king but by contract. The coinage of the Commonwealth is remarkable for the simplicity of its types and this is the only period of English coinage when the legends have been in English (Pl. IV.-12). A series of coins were struck with Cromwell's bust and superscription but, although not uncommon, they never seem to have been put into currency (Pl. IV.-14).

The modern coinage dates from the reign of Charles II. After issuing the old denomination of hammered money in the first two years of his reign, he replaced the unite or broad in 1662 by the guinea (Pl. IV.-15), so called from the provenance of its gold, still a 20s. piece. It was not till 1717 after various oscillations that its value was fixed at 21s. His silver coins were the crown, half crown, shilling, etc., all regularly and beautifully struck by Jan Roettier with the new mill which was then established at the mint. In 1672 he introduced the bronze halfpenny and farthing with the Britannia type. The finest coin of his reign is not a regular issue. It was the "Petition" crown (Pl. VII.-14) made by Thomas Simon, engraver at the mint under the Commonwealth, and bears on the edge a petition to the king that he might be given the same office under the new régime. The coinage of the 18th century calls for no remark; one may just mention the practice of recording the provenance of the metal of particular issues as in the VIGO issues of Anne struck from captured Spanish bullion in 1702, the Welsh Copper Company shillings of George I. and LIMA coinage of George II. made of bullion brought by Anson from his voyage round the world. Towards the end of the century the scarcity of government silver was largely made good by Spanish dollars, with or without a bust of George III. countermarked upon them, and by tokens issued by the Bank of England while the deficiency in copper was made up by the private issue of vast numbers of tokens. In 1816 the great recoinage took place with the introduction of the sovereign and silver coins each with Pistrucci's design, St. George and the Dragon. In 1848 in the reign of Queen Victoria the 2s. piece (florin) was issued and proved a most popular coin; the double florin which was first issued in 1887 did not take the public fancy and the practical disappearance of the crown piece also from circulation reflects the public prejudice against large coins. The gold sovereign was last struck in 1917 but it had disappeared from currency in 1914 soon after the outbreak of war, after a career of three hundred years as sovereign, unite, guinea, and again sovereign.

Wales has never had a regular coinage but there exist two unique coins of Welsh kings, a penny of Howel Dda (c. 910-40) and another of Llewellyn (1075-79).

Scotland.—The coinage of Scotland followed similar lines

to that of England as regards types and weights: the earliest coins are silver pennies (Pl. IV.-16) resembling the contemporary coins of England. The silver coins are baser and of inferior work but the rarer gold coins present several remarkably fine pieces of workmanship (Pl. IV.-17); the Scots coinage decreased in quantity after the union of the crowns in 1603 and ceased in 1709 after the union of the parliaments. The only extensive and varied coinage is that of Mary Queen of Scots.

Ireland.—Ireland had an extensive silver coinage in the 10th century, mainly copies by Danish kings, Sihtric III. and his successors, of the Anglo-Saxon coinage. The Anglo-Irish coinage began in 1177 with pennies and halfpennies of John, the only coins to bear his name which does not occur on the English coins. The quality of the coinage became more and more debased, reaching its final degradation under the Tudors. Gold was never struck by the government but copper was introduced quite early. The Civil War as in England produced a number of siege-pieces, notably the Inchiquin and Ormonde money. James II. in his campaign in Ireland issued vast numbers of gun-metal coins ranging from the 2/6 downwards. These were to be cashed for silver when he regained the throne. They are unusual as bearing the date in months. Irish coinage under the British régime did not actually come to an end until the reign of George IV., the last issue being in 1822. In 1928 coinage by the Irish Free State was introduced.

We may note that the Isle of Man had its own coinage from 1709 under the Earls of Derby to 1864 under Victoria and that the Channel Islands of Jersey and Guernsey have had their own bronze coinage for over a century.

ASIATIC COINS

Achaemenids.—The ancient kingdoms of the nearer East, Sumerian, Assyrian, Babylonian and Hittite, had no coined money, nor had the earlier Achaemenids of Persia. Not till after Cyrus conquered Lydia in 546 B.C. did the Persians learn the art of coinage. It is not certain which Achaemenid ruler first struck coins but it was likely Darius Hystaspes (521-486) as Herodotus suggests. The coins of the dynasty were the daric (Pl. I.-4) (i.e., the coin of Darius) of gold of very pure quality and the siglos in silver. Thus early we have the relationship of sovereign and shilling anticipated, for 20 sigloi (shekels) made a daric which weighed a little more than an English sovereign. The types of both coins were the same: obverse the Persian king in a kneeling position holding a bow in his left hand and a spear in his right; the reverse bears no type but only a rough irregular incuse caused in the striking. In shape they are roughly oval being struck from round or rather egg shaped globules of metal. These pieces were uninscribed and remained in issue unaltered in type till the fall of the empire. The issue of gold was the royal prerogative, but the conquered Greek and other cities and states were allowed to issue silver and copper while a number of Persian satraps struck silver in their own names; to this latter class we owe a number of the earliest and finest portraits on coins. On the fall of the empire, various satraps, like Mazaeus who ruled Babylon for his new master Alexander the Great, struck silver coins of their own.

Parthians.—In the middle of the 3rd century the Parthians rebelled and cast off the Greek (Seleucid) yoke and soon became a great power in Persia. They had an extensive but monotonous coinage in silver (tetradrachms and drachms) and copper. The tetradrachms and drachms bear the bust of the king and Arsakes, the founder of the dynasty, seated holding the Parthian bow on the reverse of the drachms. The usual reverse on the tetradrachms is the king seated receiving a wreath from a Victory or a city goddess. The coins do not bear the name of the issuer but that of Arsakes, the founder of the dynasty, and the inscriptions range in length from the simple (coin of) "king Arsakes" to legends like (coin of) "the great king of kings, Arsakes, the just, the illustrious, the divine, the friend of the Greeks." After Phraates IV. the coins are dated in the Seleucid era; on the later coins the Greek becomes corrupt and broken and is joined by an inscription in Pehlevi, a language now more intelligible to those who used the coins.

The kings of Persis, who became independent about the same

time as Parthia, began their series with very fine portrait tetradrachms but the coins rapidly degenerated; their reverse type a fire-altar with or without attendant priests was revived by the Sassanians so that it had a life of nearly a thousand years; numerous debased silver, almost copper, tetradrachms of the rulers of Characene and of the Omani on the lower Tigris down to the sea still exist to record the names of forgotten rulers.

Sassanians.—In the beginning of the 3rd century A.D. Ardashir, a native Persian prince, overthrew the last remnants of Parthian power and founded the great Sassanian empire which ruled all western Asia. The Sassanian coinage was very extensive in silver and the early emperors regularly coined gold although the latter was rare. The copper coinage also seems to have been small. The coin-types throughout the dynasty are the same for all metals; on the obverse is a bust of the king with a long legend of the form (Ardashir, etc.) "worshipper of Ahura Mazda, divine king of kings of Iran," and on the reverse a fire-altar usually with two attendant priests and the legend "the fire of (Ardashir or other emperor)"; from the time of Kobad the reverse legend gives the mint and the regnal year of issue. The standard of the gold coins is derived from that of the Roman solidi; the silver coins are drachms following the Parthian standard and are remarkable for their broad thin fabric which was copied by the Arabs from their silver coins (Pl. III.-11). The execution of the portraits especially in the 3rd and 4th centuries is remarkably fine.

Caliphates.—The early Arabs were unacquainted with the art of coinage which had died out in Arabia with the extinction of the Himyarite kingdom in the south; it was not till the conquering armies of Islam had wrested Syria from the Byzantines in the east and overthrown the Sassanian empire of Persia in the west that they became acquainted with regular currencies and with the sudden accession of wealth found the need of one. At first they issued gold and bronze pieces imitated from contemporary Byzantine coins, modifying the cross on the reverse of the latter somewhat to suit Muslim susceptibilities; the earliest silver coins were copies of late Sassanian coins with the addition of *bismillah* (in the name of God) on the margin (Pl. III.-12). The need for a purely Arab coinage worthy of the now vast Arab empire was soon felt and towards the end of the 7th century the fifth Omayyad Caliph 'Abd al-Malik (A.D. 685-705) instituted a coinage more in keeping with the principles of Islam. This coinage was of gold, silver and copper and the names *dīnār* (denarius aureus), *dirhem* (drachm) and *folis* (folles) were borrowed from the Byzantines, as also the weights of the gold and bronze. It is interesting that the gold and bronze (Pl. III.-13) kept the thick fabric of the Byzantine originals while the silver retained the thin fabric of the Sassanian drachms; it was some centuries before this distinction of fabric disappeared. The strict interpretation of some sayings of Mohammed on image-making had removed a vast field of activity from the Muslim mint-engraver by limiting him to legends instead of types. This however gave Arab coins a historical value which the coinage of no other race possesses. From the earliest times they bear the mint and date and in time the ruler's name and title often with valuable genealogical data and titles of historical interest. Every Muslim claimant to sovereign power took the earliest opportunity of striking coins and we possess coins of rulers and pretenders known to have had the briefest reigns and in some cases their coins still testify to the existence of rulers unrecorded by history.

The dirhem of 'Abd al-Malik bears on the obverse the Muslim profession of faith. "There is no god but God: he has no associate" and around is the marginal legend. "In the name of God this dinar was struck at — in the year —." The reverse area has a quotation from Koran CXII. "God is alone; God is eternal: He begets not and is not begotten nor is there any one like unto Him." Around is Koran IX. 33. "Mohammed is the Prophet of God sent with guidance and the religion of truth to make it prevail over all other religions averse though the idolators may be." This type of coin (Pl. III.-14, 15), issued from Spain and Morocco to the borders of China, gave Muslim coinage the character which it held for centuries. In mid 8th century the 'Abbāsids overthrew the Omayyad Caliphate but at first made

little change in the coinage. The long reverse formula was replaced by the simple statement "Mohammed is the Prophet of God" and in time the caliph's name was added and at the provincial mints that of the local governor and in the 9th century a second marginal inscription was added: "To God belongs the order before and after and in that day believers shall rejoice in the help of God" (Koran XXXI. 3-4). Among the more remarkable coins of this series are those of Hārūn al-Rashid (786-809) which bear the name of his vizier and boon companion the ill-fated Barmecide Ja 'afar (Pl. III.-15), whose fame, like that of his master, has been spread by the *Arabian Nights*. The extensive gold coinage of the 'Abbāsids became one of the great currencies of the mediaeval world and Offa in his efforts to found an English coinage imitates a dinar of al-Manṣūr (A.D. 754-775).

The 'Abbāsīd caliphate broke up in the 9th and 10th centuries and the succeeding independent governors regularly put their own names on the coins although they retained that of the caliph of Baghdad whose spiritual authority was still recognised. Among such dynasties were the Omayyads of Spain, who issued an extensive coinage mainly in silver from the middle of the 8th till the end of the 11th century, the Idrisids, Tūlūnids, 'Aghlabids and Ibhshidids, all short-lived dynasties in North Africa and Egypt, coining mainly in gold. In Central Asia we have the extensive coinage of the Sāmānids of the days when Samarkand and Bukhārā were great centres of culture and poured their wealth into northern Europe to buy costly furs as the great finds of Arab coins around the Baltic show. The 'Abbāsīd coinage continued down to the 13th century but Baghdad was almost its only mint in its latter days; its last coins are very handsome large gold pieces. Minor dynasties mainly of Persian origin were the Tāhirids, Saffarids and Būyids whose silver coins are still valuable historical documents. In the 10th century the Fātimid caliphate, of Shī'a origin, arose in western Africa and in time conquered Egypt. Its extensive currency of gold introduced a new type of dinar with legends of the usual type but arranged in three concentric circles (Pl. III.-16); they held Sicily for a time and the coins struck were imitated by their Norman successors. A little later the Turks arose in the West, swept before them the smaller dynasties and ultimately ruled all western Asia. As the Ghaznawids, they ruled in Afghanistan and part of India; Mahmūd of Ghazna struck coins with inscriptions in Arabic and Sanskrit, the latter for his Indian dominions (Pl. V.-11). His regular gold coinage and those of the great Seljuk Tughril Bey are among the last issues of the old type and in the 13th century we have a series of remarkable innovations. The descendants of the original Seljuk conquerors divided their conquests in western Asia into numerous small states. Their scarce gold coinage follows orthodox lines, while giving a wealth of historical information, but the most remarkable of their issues was an extensive series of large copper coins bearing a remarkable number of different types borrowed from all sources, ancient Greek and Roman and Byzantine. They seem to have taken a childish delight in reproducing any coin-type or even picture that took their fancy. Such are the coins of Karā Arslān (1168-1174) with reverse the familiar Byzantine type of Christ seated or of Alpi (1152-1176) with the virgin crowning a Byzantine emperor (Pl. III.-17). Their silver coins were directly influenced by the aspers of the Byzantine emperors and more particularly by those of the empire of Trebizond. From the latter comes the type of a horseman with a mace over his shoulder (Pl. III.-3), popular with the Seljuks of Asia Minor. Notable among the silver coins of this period are those of Kai Khusru II. (1236-1245) with the Lion and Sun type (Pl. III.-18), the horoscope of his beautiful Georgian wife whose portrait he even wished to put on his coins. It is these Turks, Seljuk, Ortukid and Ayyubid who were the "Saracen" opponents of the Crusaders, the best known of them being Saladin, the Ayyubid sultan of Egypt and Syria; his silver coins and those of his family give their titles at great length to the exclusion of religious legends. During this period and a little later some of the most beautiful coins the Muslim world has produced were being struck by the Almohads and Almoravids in western Africa. These large thin pieces of fine gold (Pl. III.-19) bear very long genealogical and

religious legends written in a beautiful and often elaborate script. Ibn Battūta, the famous Moorish traveller, remarks that nowhere were the dinars so large and beautiful as in his native land.

In the 13th century we note that the Mongols swept through all Asia except India until checked on the Egyptian frontiers. Of the Mongol lines, the Khans of the Golden Horde in the north issued an extensive series of small silver coins; the greater and wealthier line of the Ilkhans of Persia struck large and handsome coins in all three metals, with the Khan's titles in Mongol on the reverse and the Mohammedan creed in the Shi'a form on the obverse. In Egypt the Bahri and later the Burji Mamluks struck a series of large gold coins down to the 16th century; their silver coins are rarer. In the 14th century the great Tamerlane (A.D. 1369-1404), a distant descendant of Jenghiz Khan, revived the power of the Mongols; the majority of his coins (silver and copper) bear the name of his nominal sovereigns Suyurghatmish and Mahmud on the reverse and the kalima on the obverse. His son and ultimate successor Shāh Rukh introduced a new type of dirhem, obverse kalima with the names of the first four caliphs on the margin and his titles on the reverse, which remained popular throughout the 15th, 16th and early 18th centuries; gold was not struck in Asia during this period. In the meanwhile the eastern half of the Muslim world was passing to the Ottoman Turks. Their coinage of gold and silver, which became gradually baser and baser, and bronze, is monotonous in its legends of stereotyped titles and mints only. Their wealth of mints gives their coins a certain historical interest as they trace the expansion and decline of Ottoman power in Europe, Asia and North Africa. A notable feature of the Turkish coinage is the tughra, an elaborate monogram formed of the sultan's name and titles which occupies one side of the coin from the 16th century onwards. Latterly Constantinople and Egypt were the only Turkish mints of importance. The coinage of Morocco rapidly degenerated in every way from the 16th century onwards, though its most recent issues struck in Paris, Berlin and Birmingham show an improvement.

Persia.—The earlier coins of the shahs of Persia are descended through the Shaihanids from those of Shāh Rukh; at first they are large thin silver pieces of Central Asian style but in the 18th century the fabric changes and the coins become smaller and thicker as in India. The coins, especially the larger pieces, are remarkable for their fine calligraphy; the legends are usually in the form of rhyming couplets; gold is not common till the 18th century. Copper was not a regal but a local issue and each city issued its own which are remarkable from the fact that each has some type, usually an animal. Some of the products of the Persian mint are of huge size; these are pieces struck for presentation to distinguished officials, for example a gold piece of 80 tumans weighing over a pound. In the latter part of the 19th century Nasir al-Din (1868-1896) abolished the provincial mints and instituted a coinage from a central mint in Tehran with European machinery. Henceforth the coins of Persia bear the portrait of the shah on the obverse and the "lion and sun" on the reverse.

Afghanistan.—The emirs of Afghanistan who became independent of Persia in the 18th century and carved out a kingdom at the expense of their neighbours in Persia, Central Asia and India, struck coins in gold and silver on the standards of the Moghul emperors whose poetical legends they also copied. At the end of the last century a mint on European lines was established in Kabul and the high flown distichs were replaced by a representation of a durbar hall. The Afghan coinage of the 19th century has been mainly silver although in its early days gold also was common.

Of the various smaller modern dynasties who ruled Central Asia till the Russian conquest, the emirs of Bukhara and of Khokand are notable for their extensive issues of gold pieces, to the practical exclusion of other metals.

India.—There is no reason to doubt the independent origin of coinage in India although it was soon so much modified by Greek influence that the question was long disputed. The earliest coins are pieces of silver (Pl. V.-3), very commonly square, and of copper punched with various symbols on both sides; of about the same date are the square and round cast copper pieces with sim-

ilar but less varied symbols. These pieces circulated all over India and belong to at least the 4th century B.C. although they circulated after this date and may be somewhat earlier. Contemporaneously from the 3rd century onwards are the copper coinages of numerous states and dynasties which show increasing Greek influence and whose few silver coins are directly influenced by the hemidrachms of the Greek rulers of N.W. India of the 2nd century B.C. The types of these are of considerable mythological and religious interest. Technically they are interesting as showing the evolution of a type from a series of separate punches to the grouping of the punches on a die.

Early in the 2nd century B.C. the Greeks of Bactria began to invade India and their coinage is remarkable for its fine series of portraits and for the number of names it records of rulers otherwise unknown (Pl. V.-1). Prakrit legends begin to appear alongside of corrupt Greek; the Greek in time becomes more and more corrupt as the Greek rulers were replaced by Scythian and Kushan invaders who copied their types. The Greek deities gradually give place to Indian ones on the coins. In the middle of the 1st century A.D. the Kushans founded a great empire in N.W. India; they have left a wealth of gold and copper coins with legends in an Iranian language in a corrupt Greek character;—at this period Roman gold in enormous sums went to India every year and was recoined there. The Kushan coins (Pl. V.-2) bear on the obverse the king sacrificing and on the reverse deities of all the religions of the time, Greek, Roman, Zoroastrian, Hindu and Buddhist. This type of king on obverse and deity on reverse became the general type of North Indian coinage for the next thousand years; the Kushan coinage continued, rapidly degenerating till the fourth or fifth century, over a much more limited area; the type was continued by the kings of Kashmir down to the 10th century and adopted and modified by the great Gupta emperors in the 4th century. The latter struck an extensive gold coinage with long legends in poetical Sanskrit and many interesting types, often medallion (Pl. V.-5) in nature, but, on their coins for general currency at least, always betraying the Kushan prototype. Among the more notable Gupta coins are those that commemorate Sandragupta's horse-sacrifice, or those that record his skill as a lyrist, to which he also testifies in his inscriptions. The art and correct Sanskrit legends of these coins are in keeping with the great Hindu revival of the period. In Western India a dynasty of Western Satraps of Persian origin had been ruling since the 1st century B.C. Their extensive coinage of silver only is dated and therefore of a historical value unusual in Indian or any early coinage (Pl. V.-4). They look modern in that they bear on the obverse a bust of the ruler; they resemble Roman denarii and may have been influenced by them but their prototype is rather to be sought in the hemidrachms of the later Greek kings of India. This kingdom was overthrown by the Guptas at the end of the 4th century and they at once began to imitate this silver coinage not only locally but also in their own territory which seems to have had hitherto no silver coins. The barbarian Huns who destroyed the Gupta and other civilisations in the 6th century have left numerous coins, imitated from Sassanian, Gupta or Kushan prototypes. Degenerate copies of these seem to have been the coinages of Northern India till the revival of various Hindu dynasties from the 10th century onwards. A notable innovation was the neat silver coinage of the Shahis of Gandhara of the "bull and horseman" type in the 9th and 10th centuries (Pl. V.-6), extensively imitated by the Mohammedan conquerors of India and the contemporary minor Hindu dynasties. The other type favoured by the mediaeval Hindu dynasties for their gold coinage was that of a seated goddess—going back to a Gupta reverse—and an inscription with the king's name on the other side (Pl. V.-7).

The coinages of Southern India form a class by themselves. In the later centuries B.C. and early A.D. the Andras ruled a great kingdom in central South India; their coinage is mainly of lead and has types of the usual indigenous character. The later mediaeval dynasties of South India struck coinages mainly of gold, the type of which is usually the badge of the dynasty; the Cheras (Pl. V.-8) of Malabar for example had an elephant and the Chalukyas of the Deccan a boar (Pl. V.-10), the Pandyas a fish and the

cup-shaped pieces of the Kadambas bear a lotus. The Chola dynasty introduced under northern influence the type of a king standing on obverse and on the reverse the king seated, which spread through South India and was taken to Ceylon by the Chola conquest and adopted by the local rajas there (Pl. V.-11). The great Hindu kingdom of Vijayanagar (Mysore) has left a large series of small gold and copper coins with the types of various deities which had considerable influence on the modern coinages of Southern India including those of the various foreign companies.

The earliest Arab invaders had reached India in the 8th century and founded a dynasty in Sind which has left numerous very small silver coins of the Omayyad type. Not till the 11th century was India seriously affected by Muslim invasions when Mahmud of Ghazna (Pl. V.-11) conquered the Punjab. His empire was short-lived. In 1193 the Ghorid Mohammed bin Sam defeated the allied Hindu forces and became lord of India. His descendants ruled Northern India from Delhi till the Mogul conquest. Their coinage is varied and extensive, mainly gold and silver tankas (or rupees) of 178 grains. They are large thick pieces with the profession of faith on one side and the name of the king, mint and date on the other. A feature of this coinage is the unsuccessful attempt made by Mohammed III. b. Tughlak (A.D. 1324-1357) to replace gold and silver coinage by brass tokens. Gold was hardly issued at all in the 15th and 16th centuries and for a time the coinage was mainly billon. Sher Shah (1539-45) (Pl. V.-12), one of the ablest of the line, issued a large silver currency of a type, kalima and names of the four caliphs, which was imitated by the Mogul successor of the Suris. During the latter half of the period of the sultans of Delhi, various dynasties made themselves independent; such were the rulers of Bengal, Gujarat, Jaunpur, Malwa, etc., whose coins all follow the standards of the central power. Those of Bengal are mainly silver rupees with rare gold; the currency of Jaunpur, gold and billon; Malwa and Kashmir gold and silver coins were square.

The coinage of Bāber and Humāyūn, the first two of the Mogul conquerors of India, are not extensive and are of Central Asian types. With the next two, the Great Moguls Akbar (Pl. V.-13) and Jahāngir, we have a series unrivalled for variety and within their limitations beauty:—the gold coins of Jahāngir are noble examples of Muslim calligraphy, an art evidently cultivated as much as painting at his court (Pl. VII.-13). The mints of the Mogul coins reflect dynastic fortune—even Shāh Jahān's brief occupation of Balkh is at once recorded on a gold mohur. The close association in the Muslim mind between sovereignty and the right of the coinage is exemplified in the existence of the coins of many pretenders to the imperial throne, some of whom we know from history to have had the briefest spell of power. The general type throughout is the same. In the 16th century the type that goes back to Sher Shah prevails, the Kalima with the names of the first four caliphs and the emperor's titles on the other side; Aurangzib replaced the confession of faith by the mint and date and this remained the usual type till the end of the dynasty. The emperor's name is usually enshrined in a Persian couplet to the effect that the metal of the coins acquires added lustre from bearing the emperor's name. Nearly fifty such verses are found on Jahāngir's coins. The latter's reign is also remarkable for the series of coins bearing the sign of the zodiac and the set of portrait mohurs, one of which represents him holding a wine-cup. He also allowed his wife Nūr Jahān to strike coins in her own name, and she is also said to have inspired the issue of the zodiacal series. From the beginning of the 18th century the coins become stereotyped and the epigraphy loses its beauty; numerous native states began to arise and throw off the Mogul yoke, but right down to the middle of the 19th century they continued to coin on Mogul lines. The English and French East India Companies for years copied the native types from the coinages and did not strike on European lines till the 19th century. The right of native states to mint their own coinage has been gradually curtailed by the British government and there are now very few independent coinages. The most important native state mint at present is Hyderabad, which a few years ago instituted a

mint with European machinery. Before leaving India we may just mention the extensive coinage in gold and silver with Sanskrit legends of Nepal, which is still being issued, the long series of octagonal gold and silver of Assam struck down to the British conquest, and the brief coinage of Burma in the 19th century.

Chinese.—In spite of the very early references to money in Chinese literature, there is no reason to believe that the earliest coins are much older than the seventh century B.C.; that is to say that coinage originated in the Far East about the same time as it did in the west and independently. The earliest Chinese coins are small bronze spades and knives, copies of the spades and bill-hooks and other small articles of husbandry that had been used for barter. The knives are about six inches long and bear the value and name of authority issuing it; *pu* money, a modified form of the spades circulated widely in the 5th and 4th centuries B.C. Small change was supplied by cowrie shells in this period, as it had been long before the invention of a coinage. There was an issue of bronze cowries in the 7th century B.C. Round money with a hole in the centre was issued as early as the 4th century but it was not till 221 B.C. that the reforming Shah Huang Ti (221-210 B.C.) superseded all other currencies by the issue of round coins of half an ounce (*pan-liang*), which were continued by the Han dynasty. This coin became gradually reduced and debased and was replaced in 118 B.C. by the Emperor Wu Ti's five-chu piece which remained the coin of China for the next eight centuries; a break in the monotony of the regular coinage is formed by the archaistic innovations of the usurper Wang Mang (A.D. 9-22) who issued a modified form of the *pu* and knife currency and a new round coin (*ho tsien*). The history of Chinese coins is the history of a series of gradual debasement of the government currency until it is overwhelmed by the increasing activity of forgers and a new coin is instituted. On one occasion at least the most skilful of the forgers were given work at the government mints. The five-chu piece lasted till the rise of the T'ang dynasty when the emperor Kau Tsu in 618 issued the *Kai-yuan* coin (Pl. V.-16) which gave the coinage of all the Far East its form till the end of the 19th century—a round coin with a square hole and a four character legend of the form "current money of (regnal period)." The Southern Sung dynasty (A.D. 1137-1278) dated their coins on the reverse in regnal years and the Ming dynasty (A.D. 1368-1628) put the mint name on the reverse as did the Ching dynasty (A.D. 1628-1911), the latter giving it in Manchu characters. Paper money has been in use in China since the 9th century and was current almost to the exclusion of regular coins under certain of the Mongol emperors, for example Kublai Khan, whose paper money is described by Marco Polo. For over 2,000 years the copper cash with occasional multiples of it was the only coinage of China; gold and silver were current by weight only, the latter in the form of boat shaped ingots. The monotony of the series is only rarely broken as for example by the nail-mark of the emperor Wen-Teh on the Kai-yuan pieces, an issue of lead coins in the 12th century and the issue of large token pieces (Pl. V.-17) going up to 1,000 cash in value during the Tai Ping rebellion when the rebels held the copper mines. With the increasing popularity of Spanish Colonial and Mexican dollars as a silver currency in China, several attempts were made to institute a silver coinage in the 19th century; not till the very end of the 19th century were mints established to strike silver and copper coins of European style in all the provinces. One of the last of these, a rupee of Sze-Chuan, was the only coin of the Chinese empire to bear the head of an emperor. This was because it was intended to compete for Tibetan trade with the Indian rupee. Under the Republic, coins were at once struck with the portraits of Sun Yat Sen and Yuan Shih Kai and the various generals who have since been fighting for China have issued their own coins with their portraits. A feature of the issues of the latter has been the number of gold coins they have issued, for the first time in Chinese history. The very extensive series of talismans, coin-like in shape but usually larger should be noted. Many are Taoist and Buddhist in their legends and types; others are simply lucky pieces.

Japan.—The art of coinage was borrowed from China by Japan whose first bronze coins were issued in A.D. 708. Twelve

Henry VII. of England. 13. The Great Mogul Jahangir (1610) India. 14. Charles II. "Petition" crown made by Thomas Simon

different issues were made down to the middle of the 10th century, each of a different reign. For the next six hundred years, however, no government coins were issued and the currency was supplied by imitations of contemporary Chinese coins made by the great nobles. In the 17th century the copper *kwan-ai* (Pl. V.-20) was first issued in 1624 and remained in vast variety the usual issue for over two centuries. The *ei-raku* and *bun-kyu* sen of the 19th century were the only other regular copper coins. Unlike China, Japan has had a gold and silver currency since the 16th century. The gold coins are large flat pieces in the shape of rectangles with circular corners the largest size being *obans* and the smaller *kobans*; these bear various small official stamps and a large signature in ink of a mint official. They range in length from 6 inches to $\frac{1}{2}$ inch. Other gold pieces are the small rectangular pieces of 1 and 2 *bu* (Pl. V.-18) issued from time to time; round gold is rare and usually of provincial mints. There have not been many issues of silver, usually in small rectangular pieces; the so-called bean money with the figure of Daikoku is not a currency but was made to add to the large, long silver presentation pieces to bring them up to a certain weight. A notable Japanese coin is the oblong silver piece struck in 1765 out of confiscated silver ornaments by an official named Taruna.

In 1869 a mint on European lines was established in Tokio and gold, silver (yen or dollar) and copper have since been regularly issued from it. The *e* sen of Japan are not coins but amulets and bear figures of Daikoku, the god of wealth, Itsibu fishing, etc.

Korea.—Korea has had a bronze coinage of the Chinese style since the 12th century, but it is only with the institution of *Shang Ping* cash at numerous mints, with an elaborate system of dating or rather numbering the issues between 1790 and 1881, that its coinage becomes common. Attempts were made to establish a silver currency during the last years of its independence. Annam began by imitating Chinese coins and had a regular bronze coinage of its own on the Chinese model from the 10th to the 19th century. Silver became common in the 19th century in the form of narrow oblong bars (Pl. V.-14). Annam also has its amulets or rather presentation pieces. These are in gold, silver, and copper with a variety of designs bearing auspicious inscriptions, quotations from the Chinese classics, etc., in addition to the king's name. The native coinage ceased when it became a French possession.

Siam.—Siam down to the middle of the 19th century struck gold and silver in the form of balls formed by doubling in the ends of a short thick bar of silver, and bearing the stamp of the reigning monarch. Since 1850 it has had a coinage on European lines with portraits and issues in gold, silver and copper and more recently in nickel.

The native kingdoms of the Malay Straits used lead for their coinage, these are usually round with Malay or rarely with Chinese inscriptions; an exception is found in the "hat money" of Pahang in the form of a hollow square with truncated pyramids and a Malay inscription along the bottom. The spear money of the Nagas, the canoe-shaped and willow leaf money of the Shan States and the "snail shells" in silver of the more primitive parts of Burma can only be mentioned here.

TECHNIQUE AND ART

The technique of production of coins and medals has remained in principle the same from the earliest period of coinage to the present day; the gradual introduction of more complicated machinery, while lessening the part played by human hand and eye in the later stages of the process, has never, unless the so-called photosculpture be acknowledged as an art, eliminated the part of the artist in producing in one form or other the actual relief of the coin or medal type.

Casting and Striking are the two sharply distinguished methods of production. The former, although it was little employed in antiquity save for large coins, may be described first, since it was the method that metal-workers used on a larger scale for the solid casting of statues, statuettes and decorative work, etc. A model was first built up in wax or clay. The process of carving the model out of a mass of wax was occasionally employed, sometimes partly combined with the building up process, but there is no evidence of this before the days of the Renaissance. Another method of producing the model, that of carving it in boxwood or pearwood or in fine stone, such as Solnhofen stone or slate, was brought to a high degree of perfection by the Germans of the Renaissance; it was almost unknown in Italy. The model once made was impressed in a mould of fine sand or other material, and a cast was made. Some of the German medallists of the Renaissance seem to have carved the design in reverse in clay (just as if they were carving a matrix in hard material) which was then baked and used as mould. In the case of small coins a number of moulds were often combined, with channels leading from one to the other. Tree-like sets of coins produced in the Far East by such casting *en chapelet* are still extant.

The coins produced by this process are seldom of precious metals and almost entirely negligible as works of art, being of the roughest kind. But the method was employed by all the greatest medallists, from the founder Pisanello, in the 15th century, onwards, in preference to the more mechanical process of striking. Casting was carried to a high degree of excellence (especially by the Germans), the ideal being to reproduce the wax model without subsequent chasing. The Italian medallists were sometimes content with the roughest representation of their work. Others depended on chasing with the burin or graver to remove the irregularities of the cast; and often the chasing was by an alien hand. Any coin or medal could be used as a model, for impressing

in moulding material, so that a new cast could be made. The vast majority of the extant medals supposed to be of the 15th or 16th century are after-casts to the nth degree. Detail has disappeared and the actual diameter has decreased since metal contracts in cooling.

The Repousse Process (*q.v.*) can of course also be used in making medals, in shells, of which the two halves are worked separately. This process was especially favoured in Holland in the 17th century. The process of pressure-casting has also, it is said, been used in recent times. Plaquettes (which are small metallic reliefs, differing from medals in being primarily decorative, not commemorative, usually one-sided and more frequently rectangular than circular) are produced like medals.

Striking of coins or medals is done by means of dies, engraved in intaglio, and impressed on the metal by blows or pressure. It is the method of impressing a signet on wax applied to a hard material, the type of a coin being, indeed, in origin and principle the signet of the issuing authority. The die had first to be engraved in a hard material. Not until Roman times was iron and occasionally steel used for this purpose. The Greeks used bronze, and analysis of two of the extremely few Greek dies that have survived shows a proportion of from 18 to 22% of tin, the rest being copper with negligible impurities. Such proportions mean a very hard quality of bronze. Modern dies are all of steel.

Hubbing and Cutting.—The die can be cut direct in reverse as an intaglio gem is cut. Or a positive punch or hub can be carved in relief in hard metal, and hammered into a piece of softer metal, which can then be hardened for use as a die. Details which cannot be produced by hubbing in this way can be finished by direct cutting. Both methods were known to the ancients; though no ancient hubs, and very few ancient dies are preserved, examination of the struck coins reveals certain details which can only be due to hubbing. The amount of time and labour saved by hubbing is immense; with one hub many dies can be made, whereas if the design is represented by a die alone, when that breaks or wears out all the work has to be done again. The instruments used in antiquity by die-engravers were the graver or scauper and the dotting-punch. There is no evidence that they used the drill, although that instrument was in the hands of every gem-engraver. The fineness of the work, the almost microscopic detail, must have necessitated the use of magnifying glasses, and there is evidence, literary and material, that these were known to the ancients. (*See ENGRAVING.*)

The Reducing Machine.—The second way of obtaining a die was invented in the 19th century and, greatly to the detriment of the art, ousted the method of cutting by hand. It involves the use of the reducing machine, which dates in origin from about 1839 (*see MINT*). The artist first makes a model in wax or plaster at least four times the size of the piece to be produced. This, reproduced in a nickel-faced copper electrotype, is placed in the machine, which works on the familiar principle of the pantograph. A tracer at one end of the proportional arm moves over the whole surface of the model. At the other end a cutting point, revolving rapidly, cuts an exact, mathematically reduced reproduction of the model. Thus is produced a punch which, when driven into another piece of soft steel, afterwards hardened, gives the die which can be used to strike the coin or medal. It is obvious that the die so produced is at least three stages removed from the artist's original model which may not be suitable for a small scale relief, however exact.

The result of the introduction of this machine has been that artists have ceased to trouble themselves about the final metallic product. Not having to cut the metal themselves, they have lost the sense of material. They model in wax or plaster, and the coins or medals which are struck from the dies produced without their intervention appear as if they were made of wax or plaster coloured to look like metal.

Preparing the Blanks.—In ancient times dies were cast, sometimes actually in globular form, more usually in a form approximating to that of the final product, with sufficient convexity to allow the metal to penetrate to the deepest recesses of the die. They could also be cut from bars. The thin blanks of the middle

ages were clipped out of a sheet of metal; in modern times they are punched out of a rolled bar. In antiquity, the lower die, which produced the obverse, was let into an anvil. The upper (for the reverse) was on the end of a cylindrical bar. The blank being placed on the anvil die, the reverse die was placed above it, and a sledge-hammer brought down on the upper end of the bar. How far the blank was heated before being struck we do not know. Such a primitive method of striking, without a collar to keep the blank in shape, produced great irregularities, splitting of the edge, double-striking and the like. The Greeks were indifferent to such things. The methodical Roman was more careful, and his coins are less irregular in shape. The sledge-hammer blows of course placed great strain on the dies. The first invention to obviate that disadvantage consisted in placing the dies in a frame and hammering wedges in between frame and dies, thus forcing the latter on to the blank between them. In the reign of Julius II. (1503-17) Bramante began experimenting with a press for papal leaden seals; and Leonardo da Vinci also made experiments with a coining press, and more particularly in the process of drawing strips of metal to the right thickness and punching out blanks. Out of such experiments grew the screw-press, the essential advantage of which was that the upper die was brought down on the blank not with a blow, but with a gradual pressure.

Relief and Lettering.—Those qualities which make a coin most serviceable as currency are not necessarily favourable to its beauty as a work in relief. The Greeks, for instance, being pre-eminently sculptors, made their coins in high relief. They thus suffered in circulation. It was only in the 4th century of our era that the relief of coins began to become flat, making way for the flat pattern-like treatment which is characteristic of the middle ages. That was not due to a recognition of the suitability of such treatment so much as to the decay of technique. In the use of lettering the Byzantines made an effort at decoration (Pl. VII.-1), but the finest development of lettering as an art on coins was left to the Muslims (Pl. VII.-13). In the 16th century printing wrought disaster on medal lettering.

The 13th Century.—Frederick II. attempted to revive the older Roman style; his gold augustale (Pl. VI.-16) has a head in medium relief, inspired by the Roman gold of the Constantinian period. But this was a false start. The beautiful Gothic coinages of the 14th century in France, England, the Low Countries, Italy, etc. (Pl. VII.-2-7), show the high-water mark of the flat pattern style, which is by far the most suitable for a coinage which has to be packed in rouleaux and circulates widely. The facing head ousted the profile under the Lower empire (Pl. VI.-9). In obedience to a Roman principle, the frontal pose was alone proper to the imperial majesty.

Towards the end of the 15th century the influence of the medal, for which the profile was alone suitable, made itself felt on the coinage and the facing head thus practically disappeared. The early testoons of the Sforzas (Pl. VII.-9) at Milan are the supreme example of profile treatment in very low relief, the finest combination of portraiture with decorative treatment that coinage can show. So far as mere engraving was concerned the highest excellence was probably reached in the 17th century by artists like Briot and Thomas Simon (Pl. VII.-14); and, so far as mere finish is concerned, a Pistrucci, a Wyon or an Andrieu leaves nothing to be desired.

The problem of composing within a circular field was solved by the ancients. The posing of a head, the combining of two or more heads in a group, whether they are jugate or addorsed or opposed, were the main problems of the obverse. The jugate or accollate position was not attempted until the 3rd century B.C. (Pl. VI.-4), and does not become common until Roman times. The confronted pose offers no difficulty, and pleased the Roman taste for symmetry (Pl. VI.-6); but the Greeks disliked it and it is not found on their coins before Roman times. The Greeks liked symmetry, but it had to be dynamic and full of movement; while they knew all that need be known about what is called heraldic opposition (Pl. VI.-1, 2), and occasionally used it, it never played much part in their designs.

The remarkable outburst of artistic effort in England in the

middle of the 8th century, when a real profile portrait head of Offa appears on his coins (Pl. VI.-11) at a time when the designs of all other parts of Europe were entirely without merit, had no duration or repercussion. Not even the excellent ornamental designs on the Anglo-Saxon coinage of this time (Pl. VI.-12), due perhaps to Irish influence, inspired Continental contemporaries to efforts for better coins. Equally without effect was such an innovation as the type of the sovereign seated in majesty on Edward the Confessor's penny (Pl. VI.-14), as on the Great Seal. France had to wait two centuries until Philip III. (1270-85) ventured to introduce the majesty-type (Pl. VI.-22). The Norman Conquest caused a definite set-back in English art.

Germany.—In the next period we must turn to German lands to find the first signs of relief from the degradation of the engraver's art. About 1125 the curious pieces known as bracteates (Pl. VI.-15), extremely thin and bearing on one side only a type which shows through on the reverse, began to be produced in Thuringia and Lower Saxony. The designs—the figure of the king seated facing, the half-figures of king and queen side by side, the emperor on horseback, the figures of saints, often in an architectural setting, and the like—are a not unworthy reflection of the greater art of the Romanesque period. The style reaches its zenith in the second half of the 12th century under Frederick Barbarossa and Henry VI., when the coins sometimes attain a diameter of 50 millimetres. It was, however, in the middle of the 13th century that the real revival began.

A similar effort was made by the little republic of Ragusa in the same century. But other States, though they wisely did not attempt to attain high relief, did begin to play with the idea of making their coins interesting or significant. Florence placed on the gold coins, which were to become world-famous as florins, its graceful lily and the figure of St. John the Baptist (in 1252). Venice started its equally famous gold sequins or ducats in 1280 with the interesting types of the figure of Christ blessing in a border of stars, and of the doge receiving the gonfalon from St. Mark (Pl. VI.-18). These types were not entirely new; they had been already used in a less elaborate form on silver.

It must have been the florin that suggested to Henry III., that enlightened patron of art, the introduction of his beautiful gold "penny" in 1257 (Pl. VI.-19). His example was followed by St. Louis in his *denier d'or* in 1266—an admirably executed coin of heraldic design (Pl. VI.-20). St. Louis must also be credited with a far-reaching innovation in the shape of the large silver piece or gros (Pl. VI.-21) of 12 deniers, the forerunner of the English groat or fourpence, though that coin did not come into regular use until 1351. The enlarged size eventually made possible the introduction of more interesting designs, though France continued to cling to conventional patterns, and England to the conventional facing head and cross. In the grossi of Wenceslas II. of Bohemia (1278-1305) the opportunity afforded by the larger flan was seized for a fine heraldic design.

The 14th Century.—But the time of Edward III. and his contemporaries is the golden age of European coinage. There is no distinction in style between the Anglo-French coins and those of the French kings, and foreign workmen were employed at the English mint. At this period there is no evidence of an independent English art. The fine period of the Anglo-French coinage closes about 1368; the gold coin of the Black Prince issued at that time is a distinct attempt at portraiture on a small scale (Pl. VII.-5). In England we have the beautiful, but abortive first issue by Edward III. in 1343 of the gold florin (Pl. VII.-3) and smaller denominations: the most beautiful coins in the whole English series, but demonstrably the work of two Florentines, Giorgio Chierichino and Lotto Nicolini. These coins are followed by the gold noble, the obverse bearing the king in his ship as type (Pl. VII.-4). In 1465 Edward IV. introduced a type of rude strength, the angel (Pl. VII.-8), in which there is something peculiarly English, especially in contrast with the St. Michael on the French coins of a century and a quarter earlier (Philip VI., Pl. VII.-2) and the angelot of Louis XI.

Towards the end of the 15th century the Tudor coinage makes its appearance with a flourish; the sumptuous "sovereign" of

Henry VII., first struck in 1489, is still Gothic, but effete: it mistakes restlessness and over-decoration for strength (Pl. VII.-11). As in England, the art of coinage in the Low Countries in the 14th and 15th centuries presents no essential difference from what is to be seen in France; Germany during the same period lags far behind the West, its coinage being monotonous and crude.

Italian Influence.—It was from Italy that the new revival was to come; and the splendour of its coinage in the last quarter of the 15th century was directly due to the sister art of the medal. The portrait-medal founded by Pisanello, with his incomparable series of portraits made between 1438 and 1449, showed the possibilities of the profile relief. After a few artists, likeENZOLA of Parma, had in the '60s and '70s made groping experiments in die-cut portraits on small medals, others, notably in Milan—though the attribution of the Sforza series to the Milanese Caradosso may be baseless—succeeded towards the end of the century in producing pieces which, as we have said, reached the high-water mark of portraiture in coinage. Early in the 16th century the influence made itself felt outside Italy. It was a German, Alexander of Bruchsal in Baden, who was employed by Henry VII. from 1494 to 1509, but the beautiful profile portraits by which, from 1503 onwards, he left his mark on the English coinage are obviously inspired by the Italian fashion (Pl. VII.-12). His work sealed the doom of the facing-head on English coins although examples lingered on to the reign of Edward VI.

The Thaler.—Meanwhile Germany had taken an important step in the invention of the thaler, again the size giving greater scope to the designer (Pl. VII.-10). The Tyrolese guldengroschen of 1484—the earliest of the class afterwards generally known as thalers—is evidently inspired, clumsy though it be, by an Italian model. It is the ancestor of all the large silver coins, thalers, dalers, dollars, scudi, crowns, of the 16th and 17th centuries. It did not add greatly to the art of coinage, which attains its highest perfection on a field of not more than an inch and a quarter. For a larger field, the medallic art, unrestricted in relief by its nonuse as currency, is proper.

Portraiture.—The development of portraiture on coins, as seen in the second half of the 15th century, must be traced to the Italian medal (Pl. VIII.-1, 2). Pisanello's first medal, representing the Emperor John VIII. Palaeologus, was made in 1438 (Pl. VIII.-1). It revealed the possibilities of profile portraiture on a small scale, suitable for coinage. What the medallists showed was that modern portraits, and not mere imitations of the antique, could find a place on modern coinage. In the '60s and '70s engravers in Milan, Parma and Venice were producing both small medals and portrait-coins from dies. By the beginning of the 16th century the technical difficulties had been overcome (Pl. VIII.-3); and soon the facility afforded by striking for the mass production of medals began to have a reaction on the medallic art. The art of coinage had reached its culmination; all future developments added nothing to its artistic content, and were due merely to increased technical dexterity.

But the medal had still a course to run. The best medallists continued throughout the 16th century to use the casting process for their most important work, even when they were also die-engravers by profession. But official patronage favoured the struck medal, satisfied with number rather than quality. The technical dexterity of the modeller continued nevertheless to increase. In Germany especially, where the art of the medal culminated in the period from 1520 to 1540, a series of portraits was produced unsurpassed in the realism of their presentation and technique of casting (Pl. VIII.-2). In Italy after about 1530 the cast medal continued to develop as an art that had lost its inspiration; facile, graceful but superficial, the elegant portraits of Pastorino of Siena (Pl. VIII.-5) are typical of the school. The modeller begins to lose the sense of material; the original wax-model is all that he cares about and the final product in metal is merely a means of perpetuating it. By the end of the 16th century the Italian vein was worked out. Italian influence, however, had passed across the Alps. German lands, especially Austria, France and Flanders, had all felt it, though none of them in the 16th century produced medallists who marked an epoch. It

remained for France in the first half of the 17th century to do for the art of the medal what Italy through Bernini did for sculpture. As masters of the baroque portrait Guillaume Dupré (Pl. VIII.-6), Jean and Claude Warin should be mentioned beside Bernini, though they too had his excessive virtuosity, as well as his brilliance. In England Thomas and Abraham Simon (Pl. VIII.-7) are almost on the same level. In Holland a native school is distinguished by hardy vigour. These developments are the last flowering of the medallistic art before the dead period of the 18th century.

The 19th Century.—In the last quarter of the 19th century the monotonous academic tradition which had reigned for nearly two centuries began to break down. The French revival took its rise in Ponscarne (1827-1903). By the study of character in portraiture, the search for a dignified realism, and for a harmonious relation of type to background, and by such external reforms as the abolition of the raised border which had so long been the fashion, he inaugurated a return to the true principles of the art (Pl. IX.-1). The French school reached its zenith under Chaplain (1839-1909), but unfortunately, thanks to modern machinery, exploited with immense skill by Oscar Roty and his school (Pl. IX.-4), the medal in French hands became a merely pretty art, lacking virility and sincerity. In Germany native vigour interposed, and the portraiture by such artists as the Viennese Anton Scharff (1845-1903) is of a fine seriousness. In England Alphonse Legros (1837-1911), with a true instinct rejecting the machine-made medal, produced a remarkable series of cast portraits (Pl. IX.-2); but he found no successor.

Later developments are not sufficiently important to require detailed mention. We are still in the age of experiment. The immense output of medals, especially in Germany, during the World War should have revealed original artists if there were any, but the only one to rise above a journalistic level was Ludwig Gies (Pl. IX.-3) and he often trespassed beyond the limits of his art. There is at the present moment no lack of fine and accomplished portraiture, and although for the purposes of mass production the use of machinery is unavoidable, the better medallists, such as Theodore Spicer-Simpson, are content to produce their works by the nobler method of casting in limited editions of two or three specimens. (See METAL WORKS; SEALS; GREEK ART; ROMAN ART.)

BIBLIOGRAPHY.—On the technique of making coins and medals see G. F. Hill, "Ancient Methods of Coining," *Numismatic Chronicle* (1922) and *Medals of the Renaissance* (1920). On the place of coins in art, the literature is confined to ancient coins: B. V. Head, *Guide to the Coins of the Ancients* (4th ed., 1895); P. Gardner, *Types of Greek Coins* (1882); K. Regling, *Die Antike Münze als Kunstwerk* (1924); G. F. Hill, *Select Greek Coins* (1927). (G. F. H.)

TOKENS FOR WAR SERVICE

From the earliest times service of all kinds has been rewarded by honours and distinctions. We learn from Josephus ("Antiquities of the Jews") that in the 3rd century B.C. Jonathan, the high priest, successfully led the Jews in battle thereby aiding Alexander, who "sent to Jonathan, and gave testimony of his worth, and gave him *honorary rewards*, as a *golden button*, which it is the custom to give King's kinsmen." Later Jonathan received another golden button for similar service. These honorary rewards of golden buttons are the earliest form of medal to commemorate war service.

BRITISH MEDALS

War Medals.—The earliest medal in existence struck for an Englishman for war service is that awarded to John Kendal in 1480. Kendal was prior of the English Knights of St. John of Jerusalem and in 1480, relieved Rhodes. His medal is now in the British Museum.

Although decorative medals were common before her reign, Queen Elizabeth appears to have been the first sovereign to bestow a medal for particular military service to the Crown, this being the "ark in flood" medal (so called from its design) to commemorate the victory over the Armada in 1588. James I. (1603-1625) issued a medal "in reward for naval achievements" on

which the design was repeated.

Under a royal warrant, dated May 18, 1643, Charles I. authorized the issue of "Badges of silver, containing our Royal image and that of our dearest son, to be achieved to wear on the breast of *every man* who shall be certified under the hands of their Commander-in-Chief to have done us faithful service in the Forlorn-Hope" (i.e., the tactical advanced guard of those days and not a hopeless adventure).

During the Commonwealth, statutory provision was made for the bestowal of medals as naval awards under a minute of the council of State, Nov. 15, 1649. There was also a "Medal of the Parliament" for land service, one being awarded to Col. Mackworth, governor of Shrewsbury, as a mark of the parliament's favour. This medal was given with "a chain of gold to the value of one hundred pounds." The first English campaign medal is that issued by the Commonwealth to commemorate Dunbar, Sept. 3, 1650. A week after the battle the House of Commons authorized the medal "both for officers and men." Cromwell protested against his effigy appearing on the medal, but this was overruled, and his effigy placed thereon. The finest medals of this period are those granted to Blake, Monk, Penn and Lawson for their victory over Van Tromp, July 31, 1653. The medals are in gold, with gold chains.

One interesting medal granted by James II. was to Bishop Mew, for his services as commander of the king's artillery at Sedgemoor, 1685. Before entering the church Mew had been an able soldier, and his ecclesiastical duties had not interfered with his continued study of the military art. Almost all writers on the subject classify the "Cumberland" medal (sometimes called the "Culloden" medal) as a commemorative war medal. This is incorrect. The battle was fought on April 16, 1746, the English being commanded by the young duke of Cumberland. To commemorate his success a number of admirers formed the Cumberland Society, a rule of which was that each member on joining was to be presented with a medal. No evidence has been found to show that the victory was *officially* commemorated by the grant of a medal.

Only one medal was issued for the American War of Independence, this being awarded to a Captain Ewing who distinguished himself at Bunker Hill.

Credit is due to the Honourable East India Company for instituting the regular practice of making the grant of medals a "general distribution" and not solely to officers. Some of their early grants include the "Deccan" medal for service during 1778-84, the "Mysore" medal (1791-92) and the "Seringapatam" medal (1799), and they continued this practice until the Crown assumed the Government of India after the Indian Mutiny. The lack of medallistic recognition to the rank and file prompted Davison, Nelson's prize agent, to present a medal to every man who took part in the battle of the Nile (1798). His example was followed in 1805 by Boulton, of the Soho Mint, Birmingham, who presented medals to all ranks who had taken part in the battle of Trafalgar (1805). But, it is stated, that as the medals for the men were only made of pewter they deemed them of no value and the majority threw them away. These are the only instances of medals being awarded to service men by private individuals.

British war medals enter upon a new era with those awarded to admirals and captains for Lord Howe's victory over the French on "the Glorious 1st of June" (1794), generally known as the *Navy Gold Medals*, in that the first official reference is made to *medal ribbon* in connection with them.

The Peninsula Campaign was two years old before any medals were authorized to commemorate the successful major operations therein. The battles of *Roliça* (Roliça), *Vimiera*, *Corunna* and *Talavera* had all been fought before the *Army Gold Medals* were instituted under general order, Sept. 9, 1810. In addition to the foregoing the *Army Gold Medal* was authorized for officers, not below the rank of battalion commander, for the following operations: *Sahagun*, *Benevente*, *Busaco*, *Barossa*, *Fuentes d'Onor*, *Albuhera*, *Ciudad Rodrigo*, *Badajoz*, *Salamanca*, *Vittoria*, *Pyrenees*, *St. Sebastian*, *Nivelle*, *Nive*, *Orthes* and *Toulouse*. Originally a separate medal was awarded for each separate operation and many officers became entitled to several medals. This,

however, caused inconvenience to the recipients and a new system was instituted in 1813 under which only one medal was to be borne by each officer entitled thereto. For the second and third occasions gold clasps, the first ever sanctioned, were added to the medal ribbon, and on becoming entitled to a fourth mark of distinction the medal was surrendered and a *Gold Cross* issued in its place, on the four arms of which were inscribed the four battles for which marks of distinction had been awarded. On becoming entitled to a fifth or further marks of distinction, gold bars inscribed with the name of each battle were added to the *Gold Cross* ribbon. The substitution of a cross for a medal was never repeated.

Of the 20 operations in the Peninsula Campaign for which medals, crosses and clasps were awarded, the Duke of Wellington had distinctions for 14, viz. (a) inscribed on the *Gold Cross*:—*Roleia* and *Vimiera*, *Talavera*, *Busaco*, *Fuentes d'Onor*, (b) clasps to the *Gold Cross*: *Ciudad Rodrigo*, *Badajoz*, *Salamanca*, *Vittoria*, *Pyrenees*, *Nivelle*, *Nive*, *Orthes* and *Toulouse*.

The first war medal to be issued to all ranks, alike in all respects, was the *Waterloo Medal*—this, at the suggestion of the Duke of Wellington.

The fact that the *Waterloo Medal*, the *China Medal* (1840–42) and the *Jellalabad Medal* (1842) were given to all ranks alike without discrimination, appears to have started an agitation amongst those who had taken part in operations for which the *Army Gold Medal* and *Gold Cross* had been awarded but for which they were not eligible, owing to their rank. In this case, the Duke of Wellington opposed granting such a medal but it was adopted as the *Army General Service Medal*. The *Military Ribbon* was worn with the medal. It was usually referred to as the *Peninsula Medal*, colour being lent to the idea by Wellington's figure appearing thereon, but it included campaigns in which Wellington had no military concern. Clasps were added.

The grant of the *Army G.S.M.* naturally led to a similar medal being authorized for the Navy, the *Navy General Service Medal* which covered operations from 1793 to those off the coast of Syria in 1840. Clasps included: *Howe's Victory* (June 1, 1794), *Campredon* (Oct. 11, 1797), *Nile* (Aug. 1, 1798), *Copenhagen* (April 2, 1801), *Trafalgar* (Oct. 21, 1805), *Navarino* (Oct. 20, 1827).

Later medals commemorate service in the Crimea, the Indian Mutiny, New Zealand campaigns and those in Egypt.

The Honourable East India Company followed the example of the home Government and instituted the "India 1851" medal. Four further India general service medals have been granted to cover operations from 1849–95, 1895–98, 1901–02, and from 1908 to 1928. For the late Lord Roberts' march from Kabul to Kandahar in 1880 there is a bronze, known as *Roberts' Star*. For minor campaigns, the *General Service Medal* is granted.

Gallantry Medals, Crosses or Orders.—The most famous of this class is the *Victoria Cross* instituted in 1856. All ranks and civilians are eligible for the award, to qualify for which the recipient must have performed some conspicuous act of bravery in the presence of the enemy. The ribbon now is red (claret) for all recipients, but was previously blue for the Royal Navy. Recipients who are granted a second distinction are awarded a bar. The award carries a pension. The V.C. takes precedence of all other orders and medals (i.e., it is worn nearest the buttons of the tunic).

Other awards of lesser degree in this class are: *Distinguished Service Order*, instituted in 1886 and the *Military Cross* (1915); only officers are eligible for the award. *Distinguished Conduct Medal* instituted in 1854, also the *Military Medal* (1916); only "other ranks" are eligible for the award. *Meritorious Service Medal*, instituted in 1845, awarded to sergeants as a reward for distinguished or meritorious service; it carries a gratuity. *Conspicuous Gallantry Medal*, originally sanctioned for Crimean War only, reinstituted 1874 and now available for any war; only "other ranks" of Royal Navy and Royal Marines are eligible for the award. *Indian Distinguished Service Medal*, instituted 1907, only Indian officers and "other ranks" are eligible. The Royal Air Force has medals, etc., comparable to the foregoing.

Good Conduct Medals.—There are a number of medals

granted for good conduct combined with a prescribed number of years' service, the conditions of eligibility varying according to the service, and whether Regular, Auxiliary, Colonial, etc. The first of these medals was the *Long Service and Good Conduct Medal* instituted in 1830.

UNITED STATES MEDALS

The premier decoration of the United States is the *Medal of Honour* which is comparable to the *Victoria Cross*. It was instituted in 1862 as a reward for conspicuous acts of bravery during the Civil War. In the course of time the details of the design have changed; the present description of the Army medal is a five-pointed star superimposed on a wreath, in the centre of the star the head of *Minerva*, surrounding which is a circle inscribed "UNITED STATES OF AMERICA." The star is suspended from a bar attached to the two top points, and on the bar is inscribed "VALOUR," above which is the American Eagle. Attached to the eagle's head is a ring through which passes the ribbon. The ribbon is light blue with stars embroidered thereon, and the medal is worn round the neck. The Navy medal differs in a few details from the Army pattern. This medal takes precedence of all other United States decorations. "Medal of Honour" lapel buttons are optional for wear in civilian clothes; they are hexagonal rosettes made of light blue silk with 13 white stars. There was a *Merit Medal*, awarded with the "Certificate of Merit" for which only enlisted men were eligible, but this was abolished in 1918.

War commemorative medals follow the British practice. An interesting example is the *Civil War Medal*, on the obverse of which is a portrait of Lincoln, surrounded by an inscription taken from his famous Second Inaugural: "WITH MALICE TOWARDS NONE, WITH CHARITY FOR ALL." On the reverse is inscribed "THE CIVIL WAR, 1861–1865." The "Indian Wars" Medal is also interesting from the fact that the reverse was copied for reverses of many other campaign medals.

MEDALS OF OTHER COUNTRIES

France.—Before 1802 gallantry in the field was awarded by grants of swords of honour, muskets of honour and other weapons but in that year Napoleon instituted the *Légion d'Honneur*. The original cross of the Legion of Honour was a white enamel gold badge, with five rays of double points, each point tipped with a silver ball, the whole on a wreath of oak and laurel: in the centre of the obverse, Napoleon's effigy with "NAPOLEON" inscribed around it. The present badge is much the same in appearance but instead of Napoleon's effigy on the obverse there is a female head, and inscribed round it, "REPUBLIQUE FRANÇAISE, 1870." The order is divided into five grades: Grands Croix, Grands Officiers, Commandeurs, Officiers and Chevaliers. The Legion of Honour is the premier order of France and is only conferred for gallantry in action or for 20 years' distinguished military or civil service in peace. The *Médaille Militaire*, instituted in 1852, is comparable with the British D.C.M. It is only conferred upon general officers in command of armies and to N.C.O.s and men of the Navy and Army for distinguished service in action. It was awarded to the late Field-Marshal Lord French. As regards commemorative war medals the first is interesting, viz., *St. Helena Medal*, instituted in 1857 for operations between 1792 and 1815. The medal is bronze and bears on one side the effigy of Napoleon, and on the other, in French, "Campaigns of 1792 to 1815. To his comrades in glory, his last thought. St. Helena, May 5, 1821." Another interesting war medal is the *Pontifical Cross*, instituted in 1867, by Pope Pius IX., and granted to all members of the French forces who took part in the defence of Rome in 1867.

Germany.—A renowned German decoration was the *Iron Cross*, instituted in 1813, as a reward for distinguished service in the War of Liberation. It was revived for the Franco-Prussian War of 1870 and was again issued for service in the World War. The cross is a Maltese Cross of cast iron edged with silver. On the upper link is a crown, on the lower link the date of the campaign, that for the World War being "1914," in the centre the initial or initials of the sovereign at the date of issue. There are three classes of the Order of the *Iron Cross*, viz., the Grand Cross, dou-

FIFTEENTH, SIXTEENTH AND SEVENTEENTH CENTURY MEDALS

1. John V^{II}., by Pisanello, 1438
2. Christoph Tetzl, by M. Gebel, 1528

3. Vittorio Gambello, by himself, 1508
4. Giovanni Toscani, by Lysippus
5. Edward Courtney, by Pastorino, 1556

6. Marie de Médicis, by G. Dupré
7. George Monck, by Thomas Simon, 1660

MEDALS OF THE 19TH AND 20TH CENTURIES

- | | |
|--|--|
| 1. Joseph Naudet by Ponscarne (1827-1903) | 3. German Auxillary Service medal by Ludwig Gies, 1917 |
| 2. Thomas Carlyle by Alphonse Legros (1837-1911) | 4. Maurice Roty by Oscar Roty; 1886 |

ble the size of the ordinary cross, is worn round the neck, and is awarded solely for the winning of an important battle, or equivalent exploit. With the rank and file the cross carries with it a gratuity. *The Order of Military Merit (Prussia)*, founded in 1665, was bestowed for conspicuous war service.

Belgium.—*The Order of Leopold II.* was instituted in 1900. There are six classes. It is awarded to N.C.Os. and men and "ranker" officers for exemplary service after a number of years (20–30). *The Ordre de la Couronne*, instituted in 1897, was originally the premier order of the Independent Congo State but was transferred to the Ministry of Foreign Affairs in 1910. It is awarded to officers after a number of years' exemplary service (20–32) and to N.C.Os. after 38 years' exemplary service. *The Military Medal*, instituted in 1902, is comparable with the British Military Medal.

Japan.—*The Order of the Rising Sun*, instituted in 1875, is awarded to all ranks of Army and Navy for gallant service in war or distinguished service in peace. *The Order of the Sacred Treasure*, instituted in 1888, is awarded to both military and naval officers for meritorious service. *The Order of the Golden Kite* was instituted in 1891. There are several classes, the higher for officers and the lower for N.C.Os. and men. It therefore corresponds approximately to the British D.S.O., D.S.C., M.C. and D.C.M. The medal to commemorate the Russo-Japanese War of 1904–05 is made of light bronze.

Italy.—*The Order of Saint Maurice and Saint Lazarus* was founded in 1434, and revised in 1831, 1837 and 1855. *The Military Order of Savoy*, founded in 1815, is awarded for special distinguished war service. Medals for military valour are awarded for acts of bravery in much the same manner as British gallantry medals. *The Messina Medal* was awarded by the King of Italy to officers and men of the British men-of-war and to certain others who assisted in succouring the injured after the terrible earthquake at Messina and Reggio in Dec. 1908. The ribbon is green with white edges.

Serbia.—*The Order of the White Eagle*, instituted in 1883, consists of five classes. The badge consists of a double-headed eagle in gold, ensigned with a crown. *The Star of Kara George*, instituted in 1904, consists of four classes.

WORLD WAR MEDALS AND DECORATIONS

By resolutions passed by a committee of the Peace Conference in Paris in March 1919, it was decided that the victorious Allies and associated Powers (i.e., Great Britain and her dominions, France, Belgium, Italy, Spain, United States of America, Japan, etc.) should have a medal common to the Powers in general design. The medal was to be called the *Victory Medal* and was to be round, made in bronze (36mm. wide), the colour, surface, thickness and attachment to be similar to the French Medal of the 1870 war, on the obverse a winged figure of Victory full length in the middle, on reverse the inscription, "The Great War for Civilization," in the language of the country granting the medal, the rim plain. The ribbon to be identical for all countries and to consist of two rainbows joined by the red in the centre.

One of the objects of issuing a medal similar in design in all countries was to obviate the interchange of Allied commemorative war medals. No clasps have been issued with the medal except in the U.S. The exact conditions under which the medal was awarded varied in each country, but generally it was issued to all who went into a theatre of war in any capacity between the first declaration of war in 1914 and the date of the Armistice, Nov. 11, 1918. In the British service it was also granted for post-Armistice operations in North Russia and Siberia, ending on Oct. 12, 1919, and in Trans-Caspia, concluding on April 17, 1919. Also in the British service an emblem in the form of an oak leaf in bronze was placed on the Victory Medal to indicate that the recipient had been mentioned in despatches during the World War.

OTHER MEDALS AND DECORATIONS

Great Britain.—(a) *1914 Star* (commonly known as the Mons Star), instituted in 1917, and awarded to all ranks, including nursing staffs, who actually served in France or Bel-

gium on the establishment of a unit between Aug. 5, 1914, and Nov. 22–23, 1914. (b) *1914–15 Star*, instituted in 1918, similar in design to the *1914 Star* except that the date in the centre is 1914–15. (c) *British War Medal*, instituted in 1919. In general terms it was granted to all personnel of the Army who served overseas in a theatre of operations in any capacity during the war, and to the Navy for one month's service during the war. (d) *Mercantile Marine War Medal*, granted to members of the Mercantile Marine for service during the World War; (e) *Territorial Force War Medal*, instituted in 1920, granted to members of the T.F. and T.F. nursing service for service outside the United Kingdom during the war subject to certain conditions (those awarded the *1914 Star* or *1914–15 Star* were ineligible for the T.F.W.M.); (f) *Military Cross*, instituted in 1914, an army decoration for which only captains, junior officers and warrant officers are eligible; (g) *Distinguished Service Medal*, instituted in Oct. 1914 for other ranks of Royal Navy and Royal Marines; (h) *Order of the British Empire*, instituted in June 1917, as a reward for war service in any capacity; (i) *Military Medal*, instituted in 1916; all other ranks are eligible for the award; (j) *Silver War Badge*, instituted in 1916, issued to all ranks who served at home or abroad during the World War and who on account of age, or physical infirmity arising from wounds or sickness caused by military service, had been compelled to leave the forces; (k) *Royal Air Force*. The following decorations were instituted under a royal warrant dated June 3, 1919, and have been awarded for post-Armistice operations and peace service: *Distinguished Flying Cross*, *Air Force Cross*, *Distinguished Flying Medal* and *Air Force Medal*.

No "battle clasps" have yet (1928) been issued for the World War, although "battle honours" have been granted.

United States of America.—(a) *Distinguished Service Cross*, Army, instituted Jan. 12, 1918, awarded to those who since April 6, 1917, have distinguished themselves in connection with military operations in circumstances which do not justify the award of the Medal of Honour. (b) *Distinguished Service Medal*, Army and Navy, instituted Jan. 12, 1918, awarded for exceptionally meritorious service. (c) *Navy Cross*, terms of award similar to *Distinguished Service Cross*, Army. The United States *Victory Medal* has battle clasps.

France.—*Médaille de la Reconnaissance Française*, instituted in 1917, is awarded to persons who performed acts of devotion in the public service. The following war medals were also issued: *Médaille Commémorative d'Orient* and *Médaille Commémorative Française de la Grande Guerre*.

Turkey.—For the Gallipoli campaign Turkey issued a white metal five-pointed star, in the centre of which is the Sultan's cypher, and the characters representing "El Ghazi" (The Victorious), below the date "333" (i.e., 1915). The ribbon is scarlet moire with a white stripe towards the edges.

Japan.—This medal is similar to that granted for the Russo-Japanese War. The ribbon is dark blue with a broad white stripe.

Egypt.—*The Military Star of the Sultan Fouad* was instituted in 1919 for officers of the Egyptian Army who are mentioned in despatches for post-Armistice operations.

Belgium.—*Croix de Guerre*, instituted in 1915, awarded for exceptional acts of bravery. *Medal De la Reine Elisabeth*, instituted in 1916, and awarded to ladies, without distinction of rank, who assisted Belgians during the war. Other medals are *Médaille du Roi Albert*; *Croix Militaire*; *Décoration Militaire*; *Médaille de l'Yser*. Three medals for the general campaigns on the Continent and in Africa were also struck: *Médaille Commémorative de la Campagne 1914–1918*, *Médaille Commémorative de la Campagne d'Afrique 1914–18*, and *Étoile de Service du Congo*.

Rumania.—*Order of St. Michael The Brave*, instituted in 1916, solely for service in the field.

Portugal.—*Victory Medal* and *Medalha commemorativa das campanhas do Exército Portugues* (to which were added clasps) were issued for the general campaign.

Germany.—Several medals were issued in Germany of which the following are the most important: (a) a silver medal was struck for the *March on Paris*. On the obverse is the bust of Gen. von Kluck and "1914–1915"; reverse, a naked fury on horse-

back carrying two blazing torches and "Nach Paris, 1914"; (b) a bronze medal was struck for the anticipated German entry into Paris. Obverse the Arc de Triomphe; among rays spreading from the top "1871-1914"; in the background the Eiffel Tower, and inscribed round the whole, "Entry of the German Troops into Paris." Reverse, the 1914 Iron Cross and "Nach aussen entschlossen. Nach innen geschlossen" (Resolute in the face of the enemy, united on the home front). An attempt was made to suppress it when the German hopes were not realized, but a few specimens are in existence, one being in the British Museum; (c) the Failure Before Paris is commemorated by a cast-iron medal. Von Kluck's bust with "1914-1915" on the obverse, with an eagle perched on a gun-emplacement, gazing at distant "Paris" on the reverse; (d) the new Triple Alliance is commemorated by a bronze medal, bearing on the obverse the busts of Kaiser Wilhelm II., Kaiser Franz Josef and the sultan of Turkey, and the inscription "Glory to God alone." Reverse, eagle perched on an oak branch, with the inscription "Brotherhood in arms, 1915, Germany, Austria-Hungary, Turkey"; (e) Russian defeat at Tannenberg: medal cast in iron and bronze. Obverse, bust of Hindenburg; reverse, "Tannenberg-Ortelsburg 1914" and "Queller of the Russians, liberator of East Prussia"; (f) the battle of the Falkland isles, Dec. 8, 1914, is commemorated by a bronze medal; (g) the Submarine War medal is cast in bronze. Obverse, bust of Admiral von Tirpitz. Reverse, Neptune with trident, seated on conning-tower of a submarine, shaking his fist at the distance where are two British sailing ships, one sinking; in middle distance, another submarine, inscription, "Gott strafe England, 18 Februar, 1915"; (h) the sinking of the "Lusitania." Obverse, ticket office of the Cunard company in New York, with Death issuing tickets to a crowd of passengers, motto "Business First." Reverse, the Lusitania (showing guns, aeroplanes, etc., on board) sinking. Inscription, "No contraband" and "The liner Lusitania sunk by a German Submarine, May 5, 1915." The liner was sunk on May 7 not May 5. "The authenticity of this medal has sometimes been denied, but the fact that it was issued has been frequently admitted by responsible German authorities as well as by the artist (K. Goetz) himself" (vide *Historical Medals in the British Museum*); (i) the Zeppelin attack on London on the night Aug. 17-18, 1915, was commemorated by a medal cast in iron; (j) the failure of the Allies Dardanelles Expedition was commemorated by a satirical medal in bronze. (T. J. E.)

NUMMULITE: see PROTOZOA.

NUN, a member of a community of women, living under vows a life of religious observance (see MONASTICISM; MONK).

NUNATAK, a name applied in Greenland to a hill or mountain peak appearing above the surface of a glacier. Greenland is for the most part covered by an ice-cap of a certain thickness which moves slowly downwards to the sea. It will rise upwards and pass over a barrier if there is no outlet, but it will flow between and around mountain peaks leaving them standing as hills (nunataks) above the general surface of the ice-cap.

NUNCIO, a representative of the pope sent on diplomatic mission, sometimes called *Nuntius apostolicus*. The nuncios are of lower rank than the *legati a latere*, but have practically superseded them as ambassadors of the papacy. Nuncios were permanently established during the 16th century.

NUNCOMAR or **NANDA KUMAR** (d. 1775), Indian official, best known for his connection with Warren Hastings (q.v.), was governor of Hugli in 1756, and in 1764 he was appointed collector of Burdwan in place of Hastings, which resulted in a long-standing enmity. In 1775, when Hastings was governor-general, Nuncomar brought accusations of peculation against him, which were entertained by Francis and the other members of council inimical to Hastings. While the matter was still pending Nuncomar was indicted for forgery, condemned and executed. Warren Hastings and Sir Elijah Impey, the chief justice, were both

impeached, and were accused by Burke and afterwards by Macaulay of committing a judicial murder; but Sir James Stephen, after investigation, reached an opposite conclusion.

See Sir James Stephen, *The Story of Nuncomar* (2 vols., 1885); and H. Beveridge, *The Trial of Nanda Kumar* (Calcutta, 1886).

NUNEATON, a town in Warwickshire, England, on the river Anker, and on the Coventry canal. It is an important junction of the L.M.S.R. and is 97 m. N.W. from London. Pop. (1901) 24,996; (1921) 41,875. The prefix of the name of the town is derived from a priory of nuns founded here in 1150. In the reign of Henry III. a weekly market was granted to the prioress. Nuneaton was incorporated in 1907. The church of St. Nicholas consists of nave, chancel and aisles, with a square embattled tower having pinnacles at the angles. A free grammar school was founded in the reign of Edward VI., and an English free school by Richard Smith in 1712. The ribbon industry is of less importance than formerly, but there are ironworks, cotton, hat, elastic hosiery, silk goods, and worsted factories; drain-pipes, tiles and bricks are manufactured and coal is mined.

NUNEZ, PEDRO (PETRUS NONIUS) (1492-1577), Portuguese mathematician and geographer, was born at Alcacér do Sal, and died at Coimbra, where he was professor of mathematics. He published a translation of portions of Ptolemy (1537), and a treatise in two books, *De arte atque ratione navigandi* (1546). His clear statement of the scientific equipment of the early Portuguese explorers has become famous. A complete edition of all his writings appeared at Basel in 1592.

See F. de B. Garcão-Stockler, *Ensaio historico sobre a origem e progressos das mathematicas em Portugal* (Paris, 1819); R. H. Major, *Prince Henry the Navigator* (London, 1868, p. 55).

NUÑEZ CABEZA DE VACA, ALVARO (c. 1490-*c.* 1564), Spanish explorer, was the lieutenant of Pamfilo de Narvaez in the expedition which sailed from Spain in 1527; when Narvaez was lost in the Gulf of Mexico, Cabeza de Vaca succeeded in reaching the mainland to the west of the Mississippi, and, striking inland with three companions, reached the city of Mexico in 1536. Returning to Spain in 1537, he was appointed "adelantado" or administrator of the province of Rio de la Plata in 1540. Sailing from Cadiz in the end of that year, after touching at Cananea (Brazil), he landed at the island of St. Catharine in March 1541. Leaving his ships to proceed to Buenos Aires, he set out in November with about 150 men to find his way overland and reached Ascension (Asunción) for the relief of his countrymen there the next year. Though successful, he was sent home under arrest in 1544, and in 1551 was banished to Africa by the council of the Indies for eight years. He was recalled and appointed judge in Seville, where he died not later than 1564.

The *Naufragios* ("Shipwrecks") of Cabeza de Vaca, which relate to the Florida expedition and his journey to the city of Mexico, appeared at Zamora in 1542; the work has frequently been reprinted, and an annotated English translation was published by T. Buckingham-Smith in 1851. His *Comentarios* (1555) chronicle the events of the South American expedition. See Fanny Bandelier, *Journey of A. Nuñez Cabeza de Vaca* (ed. A. F. Bandelier, New York, 1905).

NUÑEZ DE ARCE, GASPAS (1832-1903), Spanish poet, dramatist and statesman. Deputy for Valladolid in 1865, he was imprisoned at Cáceres for his violent attacks on the reactionary ministry of Narvaez, acted as secretary to the revolutionary Junta of Catalonia, and wrote the "Manifiesto to the Nation" (Oct. 26, 1868). He served under Sagasta as minister for the colonies, the interior, the exchequer and education; but ill-health compelled him to resign in 1890.

Nuñez de Arce first came into notice as a dramatist with such plays as *La Cuenta del Zapatero* (1859), and *El haz de leña* (1872). But his talent was more lyrical than dramatic, and his celebrity dates from the appearance of *Gritos del combate* (1875), a collection of poems exhorting Spaniards to save the country from anarchy and lay aside domestic controversies. He was maintained in popular esteem as the only possible rival of Campoamor by a series of philosophic, elegiac and symbolic poems: *Raimundo Lulio*, *Ultima lamentación de Lord Byron* (1879), *Un Idilio y una Elegía* (1879), *La Selva oscura* (1879) and *La Visión de Fray Martín* (1880). The old brilliance sets off the naturalistic observa-

SCENES OF HISTORIC INTEREST IN THE OLD CITY OF NÜRNBERG

1. Entrance to the Fleischbrücke (meat bridge) one of the oldest stone bridges in the city, built 1596-98
2. Aerial view of Nürnberg looking down on Castle Hill (centre left) and its mediaeval fortifications around which the town developed. At the left is the imperial castle, and in the centre the Vestner-Turm (round tower), built 1561. Behind it in a diagonal line is the Five-Cornered Tower, in which was the torture device known as the "Iron Maiden"
3. Looking across the roofs of Nürnberg to Castle Hill. St. Sebald's church (1230-73), with twin towers, is on the left
4. House (centre) of Albrecht Dürer. It has been owned by the city since 1826, and has been restored
5. Hauptmarkt, the principal market on the Sebald side. In the centre of the square is a modern replica of the Neptune fountain, made in 1661-69 and sold by the city to the tsar of Russia. Behind it stands the church of Our Lady (1355-61) with a curious clock on which figures of the electors move around that of the emperor Charles IV.
6. The children's playground on the Pegnitz river, with the turrets and dome of the Jewish synagogue seen in the background

tion of *La Pesca* (1884) and *La Maruja* (1886). The list of his works is completed by *Poemas cortos* (1895) and *¡Sursum corda!* (1900); *Hernán el lobo*, published in *El Liberal* (Jan. 23, 1881), and *Luzbel* remain unfinished. Gracious in his vision, sincere and patriotic, his weakness was sentiment and rhetorical sympathies. (J. F.-K.)

NÜRNBERG [NUREMBERG], the second town in Bavaria in size, and the first in commercial importance. It lies in the district of Middle Franconia in a sandy, well-cultivated plain, 124 m. by rail N.N.W. from Munich. The city stands on the Pegnitz, which is here crossed by 14 bridges.

History.—The first authentic mention of Nürnberg, which seems to have been called into existence by the foundation of the castle, occurs in a document of 1050; and about the same period it received from the emperor Henry III. permission to establish a mint and a market. It is said to have been destroyed by the emperor Henry V. in 1105, but in 1127 the emperor Lothair took it from the duke of Swabia and assigned it to the duke of Bavaria. An imperial officer, styled the burgrave of Nürnberg, became prominent in the 12th century. This office came into the hands of the counts of Hohenzollern at the beginning of the 13th century. The town was ruled by patrician families. German monarchs frequently resided and held diets here, and in 1219 Frederick II. conferred upon it the rights of a free imperial town.

Like Augsburg, Nürnberg attained great wealth as an intermediary between Italy and the East on the one hand, and northern Europe on the other. Its manufactures were well known. The town gradually extended its sway over a territory nearly 500 sq.m. in extent, and was able to furnish the emperor Maximilian with a contingent of 6,000 troops. But perhaps the great glory of Nürnberg lies in its claim to be the principal fount of German art. Adam Kräftt, Veit Stoss and Peter Vischer are famed as sculptors. In painting Nürnberg claims Wohlgemuth and Dürer. A large proportion of the old German furniture, silver-plate, stoves and the like was made in Nürnberg workshops. Its place in literary history it owes to Hans Sachs and the other meistersänger. The inventions of its inhabitants include watches, the air-gun, gun-locks, the terrestrial and celestial globes and the art of wire-drawing.

Nürnberg was the first imperial town to embrace Protestantism (about 1525). The first blow to its prosperity was the discovery of the sea-route to India in 1497; and the second was inflicted by the Thirty Years' War, during which Gustavus Adolphus was besieged here for ten weeks by Wallenstein. The downfall of the town was accelerated by the illiberal policy of its patrician rulers. In 1803 Nürnberg was allowed to maintain its nominal position as a free city, but in 1806 it was annexed to Bavaria.

Population and Industries.—The population of Nürnberg was, in 1925, 392,494, more than two-thirds of whom are Protestant. The city is a garrison town. The manufactures are toys and fancy articles in metal, carved wood and ivory, which are collectively known as Nürnberg wares. It is also famous for pencils, needles, electric apparatus, chromo-lithography and motors. Nürnberg is the chief market in Europe for hops. It is an important junction for railways and is served by the Ludwig canal, connecting the Danube and the Main.

Buildings.—Considerable sections of the ancient walls and moat still remain; of the 365 bastions which formerly strengthened the walls, nearly 100 are still *in situ*, and a few of the old gateways have also been preserved. Most of the streets are narrow and crooked, and the majority of the houses have their gables turned towards the street. The general type of architecture is Gothic, but the rich details, which are lavished with especial freedom in the interior courts, are usually borrowed from the Renaissance. Most of the private dwellings date from the 16th century, and there are practically none of earlier date than the 15th century. The roofs are of red tile.

The old castle (Kaiserschloss), is placed on a rock on the north side of the town. This dates most probably from the early part of the 11th century, but it received its present form mainly during the reign of the emperor Frederick I. about 150 years later. It was restored in 1854-56. In the Heidenturm are two late Roman-

esque chapels, one above the other. Other parts of the castle are the pentagonal tower, the oldest building in the town, wherein are preserved the famous "iron virgin of Nürnberg," and other instruments of torture; the granary (Kornhaus), also called the Kaiserstallung; and the Vestnertor or Vestnerturm. The castle of Nürnberg was a favourite residence of the German sovereigns, in the later middle ages, and the imperial regalia were kept here from 1424 to 1796. Near it are the remains of the burg of the Hohenzollerns, the principal existing part of which is the chapel of St. Walpurgis, which was destroyed with the rest of the building in 1420, but was restored in 1892. Not far from these ruins stands the Luginsland, a stronghold with four corner turrets, said to have been built by the burghers in 1367 as a watch-tower against the burg of the Hohenzollerns.

Nürnberg contains several churches, the finest of which are those of St. Lorenz, of St. Sebald and of Our Lady. All three are Gothic edifices and are notable for their elaborately carved doorways, in which free play has been given to the exuberant fancy of the Gothic style. The church of St. Lorenz, the largest of the three, was built in the 13th and 14th centuries and has recently been restored. In it is the masterpiece of the sculptor, Adam Kräftt, consisting of a ciborium, or receptacle for the host, in the form of a florid Gothic spire 65 ft. high; the carving of this work is exquisitely minute and delicate. The shrine of St. Sebald, consisting of a bronze sarcophagus and canopy, in the richest Gothic style, adorned with numerous statues and reliefs, is looked upon as one of the greatest achievements of German art. It was executed by Peter Vischer, the celebrated artist, in bronze, who was occupied on the work for 13 years (1506-19). The church of Our Lady possesses some fine old stained-glass windows and some paintings by Michael Wohlgemuth. The Tuchsche altar, with its winged picture, is one of the finest works of the Nürnberg school about the middle of the 15th century. Other noteworthy churches are those of St. Jacob, founded about 1200 and restored in 1824; and of St. Aegidius.

The town hall (Rathaus), erected in the Italian style in 1616-19, contains frescoes by Dürer, and a curious stucco relief of a tournament held at Nürnberg in 1446. The building incorporated an older one of the 14th century, of which the great hall, with its timber roof, is part. The most interesting secular buildings are the houses of the old patrician families. A special interest attaches to the dwellings of Albert Dürer and Hans Sachs, the cobbler-poet. The streets are embellished with several fountains, the most noteworthy of which are the Schöne Brunnen, 1385-96, in the form of a large Gothic pyramid, adorned with statues, and the Gänsemännchen or goose-mannikin.

The Germanic national museum, established in an old Carthusian monastery includes masterpieces by Holbein, Dürer, Wohlgemuth and others. The municipal library contains many thousands of manuscripts and books, some of which are of great rarity.

NURSERIES, NURSERY TREES: see ARBORICULTURE.

NURSERY EQUIPMENT. A baby should room alone, if possible, and must always sleep alone. Nursery equipment should be simple and all furniture and fittings of a type that may be readily washed. Painted walls are preferable but fresh clean wall paper is permissible. The best floors are well oiled or waxed hard wood or linoleum with a few small, washable, cotton rugs. Muslin curtains and dark window shades permit of good ventilation and subdued lighting. The necessary furniture consists of: A table of plain wood about two by three feet in size and low enough so that the mother may reach anything on it from her chair. Two low chairs without arms; one may be a rocker. A screen with removable washable panels to be used for protection from draughts and as a rack for airing the clothing. Two accessible shelves on the wall for the toilet articles. A closet with shelves or a bureau to hold the clothing. A wall thermometer and a covered pail to hold soiled diapers.

The Bed.—A crib or bassinot may be used. The latter is advised for the first two months; the best kind is the ordinary clothes basket with handles at either end. This affords free ventilation, is easily cleaned, may be placed upon two chairs or a bench and is moved about readily. For a mattress an ordinary hair pillow

is best; a feather pillow must not be used but one of felt or kapoc is a good substitute. Large pillow cases are preferable to sheets; one to hold the mattress and so serve as a lower sheet; the other to hold the blankets and serve as an upper sheet and bed spread. A small blanket rolled tightly may be placed at the foot of the bed before the upper sheet and blankets are tucked in; this will hold the upper bedding away from the baby's feet and permit free movement of the legs. A pillow for the head is not needed.

Care of the Nursery.—The bed should be placed in a corner of the room well protected from a direct draught and too strong a light. The wall thermometer should be placed on the wall above the head of the bed. The temperature of the nursery should not be above 68° F nor below 66° during the daytime. For the first three months the proper night temperature is from 62 to 64° and later this may be reduced to from 50 to 54 degrees. In winter the proper ventilation may be secured by the use of a window board and in summer the windows, thoroughly screened, may be left open during the cooler part of the day and at night. The room should be well cleaned and aired every day and the baby in his basket taken out of the room while this is done. Soap and hot water with sunshine are the best cleaners and disinfectants to use.

The Bath.—Tub baths may be given as soon as the umbilical cord drops off, usually about the tenth day after birth. Until that time sponge baths only are permitted. The equipment needed for the bath consists of: A portable bathtub of rubber or enamel ware. Rubber apron for the mother. Small soft blanket. Supply of soft and absorbent towels. Two wash cloths; one for the face and head and the other for the body. A tray holding a cake of castile or other pure white soap, a tube or jar of baby cream, plain unscented talcum powder, a few covered glass jars to hold small squares of sterile gauze, cotton pledgets and liquids needed, safety pins of assorted sizes, a bottle of boric acid solution and a bath thermometer. These articles should be replaced on the tray after use and covered with a clean towel until needed again. When all the equipment is in place, undress the baby and lay him on the bed wrapped in the soft blanket. Put on the rubber apron and pour the water into the tub. The temperature of the water must be tested with the bath thermometer at the last moment before the bath is given. For the first few weeks this should be 100° F. From the second to the sixth month the right temperature is 98 degrees. For the remainder of the first year, 95° is proper. During the second year the temperature of the bath water may be lowered to from 85 to 90° F. When the water is at the right temperature, take the baby in your lap and place the towel about him in place of the blanket. Before placing the baby in the tub use one of the wash cloths to bathe his face with plain water. Then soap the cloth well and gently wash the head, neck and back of the ears. Be careful not to get any of the soap in the baby's eyes. Rinse the wash cloth and wash off the soap from the head and neck. Now lift the baby by placing your right hand and arm under his buttocks and your left arm under his back with the forearm supporting his head. Set him gently in the tub keeping his back and head well supported, leaving your right arm and hand free for giving the bath. Soap the second wash cloth and rub the body, arms and legs all over, gently but thoroughly. Then rinse the cloth and wash off the soapy lather. The bath should not take more than a few moments during the first few weeks, later it may be given more leisurely. Now lift the baby from the tub and wrap him in the bath towel on your lap. The drying process consists of a series of gentle pattings; do not irritate the baby's delicate skin by rubbing. The head and face should be dried first and then the arms, legs and body. Do not wash out the baby's mouth, ears or nostrils unless so advised by your doctor. If the eyes need special care they may be wiped gently with a pledget of sterile cotton wet with sterile water or boric acid solution. When this is done, the baby should be turned on his right side while the right eye is washed and on the left side for the left eye; this turning is necessary to prevent the solution used for one eye from running into the other eye. After the baby is well dried it is a good plan to smear all of the folds of the skin in the groin, under the arms and about the neck with a little of the baby cream or with olive oil. Then comes a light dusting of the body with

talcum powder and the baby is ready for his clothing, his feeding and his nap. Diapers must be changed as soon as soiled, placed in a pailful of cold water and once each day thoroughly scrubbed with soap and hot water, rinsed in hot water and then boiled for five minutes. If possible, dry the diapers in the sunlight.

Clothing.—Three points to remember about the baby's clothing are that it must be loose, light in weight and of materials that will not irritate the skin. The same weight clothing should be worn indoors both summer and winter. On very hot days the shirt, diaper and dress are sufficient. In cold weather, a light weight knitted shawl or blanket may be used for added warmth. For out of doors in cold weather, a warm cloak, hood and bootees are necessary. Socks or stockings may be worn if needed for warmth but their use is rarely desirable except in very cold weather. The list of articles needed for a layette is as follows: 6 dresses, 6 petticoats without sleeves, 4 shirts, 3 flannel abdominal bands for the first month, 4 nightgowns, 4 dozen diapers, 1 wrapper, 1 cloak, 1 hood, 4 pairs of socks or stockings, 1 light weight woollen shawl. The best materials for the dresses are; fine muslin, nainsook or lawn cloth. Do not use lace or embroidery around the neck or cuffs as it is apt to irritate the delicate skin. For the petticoats use a light weight flannel or cotton flannel. Knitted cotton goods is best for the undershirts; wool is needed only in the coldest climates. The dresses and petticoats should be made twenty inches long from neck to bottom of hem and should be opened all the length of either the back or the front. Both methods of opening have advantages. The full opening down the back permits the petticoat and dress to be drawn aside when the baby is put into his bed and so prevents soiling of the clothing. When the dress and petticoat open all the way down the front, the entire clothing may be put on as a unit. In this method, the dress is laid out flat on the bed or table with the wrong side up. The petticoat is laid over the dress with its armholes over the armholes of the dress. The sleeves of the undershirt are then drawn through the armholes of both petticoat and dress. The diaper is laid in place on top of the clothing and the abdominal band laid across the top of the diaper and the lower end of the shirt. The baby is then laid on the clothing, the band and diaper fastened in front, the arms drawn through the combined armholes of the shirt, petticoat and dress and the latter fastened in front. With this method of dressing, the baby is not turned at all and is handled only when the arms are being put through the armholes. It has many advantages as a method of dressing as the baby is disturbed so little that digestion is not interfered with, sleep comes more readily and consequently health is markedly improved. (See CHILDREN: CARE OF; INFANCY.)

NURSERY SCHOOLS. The nursery school is a comparatively modern section of education arising from the necessity of providing a suitable environment for the mental and physical development of children of pre-school age.

Great Britain.—The age of compulsory school attendance is five years, but education authorities have the option of admitting children at three years. In the 19th century the general opinion was that the children of the elementary school class were better in school than out of it, and there were large classes of "younger infants" (three to five years old), in most elementary schools in urban districts in England. In Scotland there was no general demand for the admission of children under five.

By the beginning of this century the conditions essential to the right physical and mental development of the young child were more fully understood, and the school education of the "under fives" was attacked both by doctors and educationists. The doctors asserted that epidemics were spread in crowded class rooms, and physical development retarded and impaired by lack of activity and fresh air; the educationists, that the formal instruc-

tion given in the three R's retarded intelligence.

In 1904 five women inspectors, appointed by the Board of Education to enquire into the education of children under five years of age in public elementary schools, reported in terms so adverse that in 1908 the board appointed a consultative committee to report on the school attendance of children below the age of five. The conclusions of the committee, based on a survey of the field in Great Britain and in France, Belgium, Switzerland and Germany, were that, where home conditions were satisfactory, the natural place for the child under five was the home; that "many homes now exist in which the mental and physical development of young children cannot be properly secured"; that the elementary schools were not providing the right sort of education for these children; that the children from "imperfect homes" should be sent to places specially intended for their training, the best place for this purpose being a nursery school as described in the report. The conditions there described were abundance of air and sunshine; open space; hygienic structures; opportunity for physical activity and sleep; education on kindergarten lines; training in right habits, and enlightened teachers. The board took no action, however, to establish such schools, and the local authorities increasingly excluded the "under fives."

Voluntary effort had already opened day nurseries for "under threes," and one or two free kindergartens on Froebelian lines for children from two to five. Nursery schools on these lines though in small numbers, became centres of light and healing in slum areas. The majority were held in adapted houses, seldom with more than a small garden attached, but all sought to provide conditions for healthy development of body and mind; formal lessons were replaced by training of the senses and of speech and movement; independence and self-control were encouraged; happy activity and comradeship in a friendly community fostered social virtues. The influence of Mme. Montessori was added to that of Froebel. Co-operation was established with infant welfare clinics and the public medical services. In 1914 a notable advance was made by Rachel and Margaret Macmillan, who in a riverside slum area in Deptford, London, established a large nursery school under completely open air conditions with remarkable results.

In 1918 the president of the Board of Education supported enlightened opinion by including in the Fisher Act regulations giving local authorities power to supply, or aid the supply, of nursery schools (or nursery classes) for children from two to five years of age. Again economy nipped the new growth. Few new schools were established, but grants helped to maintain those in existence. There are now 24 nursery schools in England and 12 in Scotland. Meanwhile the "under fives" have returned in large numbers to the elementary schools, the best of which are in sympathy with the new ideals.

Other European Countries.—Institutions analogous to nursery schools are, as already indicated, to be found on the continent of Europe. In Belgium they are called *écoles gardiennes* or *jardins d'enfants*, in Austria *Kindergarten* and in Germany and Switzerland *Kindergarten*, *Krippen* and *Kleinkinderbewahranstalten*. (For nursery schools in France see EDUCATION: France; INFANT SCHOOLS; KINDERGARTEN; MONTESSORI SYSTEM; and OPEN AIR SCHOOLS.)

UNITED STATES

It is evident that development of science in the fields of biology, psychology and sociology had emphasized the importance of the years from two to five, and it was recognized that during the pre-school years the child gains control of his body; develops the beginnings of response to tone, rhythm, colour and form; and forms his speech habits and acquires a vocabulary. It was shown also that the physical habits of sleeping, feeding, elimination and exercise, the mental habits of concentration, self-control and self-reliance, or their opposites, and the social attitudes

toward authority, reality and affection, whether good or bad, are developed in this period and are likely to be little changed in future years. These scientific developments led many parents to seek help in training children during the years when the child is ordinarily dependent upon the home for all his contacts. Study groups of mothers, magazine articles, and books assisted.

In 1919 the Bureau of Educational Experiments in New York city organized a nursery school to serve as a basis for studying the educational factors in the environment of pre-school children and for research. The State of Iowa in 1917 authorized the establishment of a child welfare research station at the State university which, in Oct. 1921, opened a play school to provide a laboratory in child psychology for experimental work with pre-school children. In 1916 a fund was left in Detroit, Mich., to finance a centre for teaching child care, and in Jan. 1922, the Merrill-Palmer Nursery school was established for the purpose of training pre-school children and their parents, as well as a group of prospective parents and teachers. Since that time a considerable number of institutions of college and university grade have established similar centres for training and research which have stamped the American nursery school as an agency for parental education as well as a centre for child development. Research schools also provide a laboratory for the scientific study of the pre-school child: the experimental type, organized to study and experiment with the educational factors in the environment of the pre-school child; the co-operative type, organized by the parents themselves and conducted with their active co-operation; the high-school or training school type, organized to give high-school girls training in child care; and the collegiate type, by far the largest group, organized in connection with colleges and universities for the purpose of providing a laboratory for the teaching of child care to pre-parental and parental groups. A number of nursery schools represent a combination of one or more of these types. The only outstanding American experiment comparable to the social type represented by the English nursery school is the Nursery Training school of Boston, formerly the Ruggles Street Nursery school, established in 1922.

In an educational programme for pre-school children, participation in living activities and play form the basis for physical and mental development. The essentials of the nursery school, therefore, include spacious rooms equipped for small children, with plenty of suitable play equipment, adequate bath and toilet facilities, sleeping space, a garden and outdoor equipment, and the supervision of skilled teachers. In order that the programme may be suitable for the individual child, and the parents furnished with accurate information, the services of specialists of various types must be available. On the physical side, a physician, nutritionist, physiotherapist, and dentist are essential if a complete picture is to be secured. Daily inspection of the children by a nurse is an essential service, since at these early ages they are especially susceptible to infections. A psychologist specially trained to determine the mental level and character traits of the pre-school child and a liaison officer between the school and the home are also essential. Experience has shown that the pre-school period of the child is also the most desirable time for training the parent whose ideas are then less crystallised.

NURSING. The evolution of the sick-nurse is mainly due to three very diverse influences—religion, war and science—to name them in chronological order. It was religion which first induced ladies, in the earlier centuries of Christianity, to take up the care of the sick as a charitable duty. The names of the oldest foundations which still survive, such as the Hôtel Dieu in Paris, St. Thomas's and St. Bartholomew's in London, the order of St. Augustine, the order of St. Vincent de Paul, and (in the form of a modern revival) that of St. John of Jerusalem, sufficiently indicate the original religious connection.

The training of nurses, which was inaugurated in Germany in

1836 on a semi-religious basis, received great impetus from the Crimean War, which was further emphasized by the Civil War in America and the subsequent great conflicts in Europe. The despatch of Florence Nightingale with a staff of trained nurses, to superintend the administration of the military hospitals was the direct result of the publicity given to the details of the Crimean War by *The Times* newspaper. The work undertaken and accomplished by this lady was far more important than the mere nursing of sick and wounded soldiers. She had grasped the principles of hygiene, which were then beginning to be understood, and she applied them to the reform of the hospital administration. In civil life it had a marked effect in stimulating the training movement and raising the status of the nurse. It remained for the third influence to develop systematic nursing to its present dimensions. Since 1880 advances in medical knowledge, particularly in respect of bacteriology, antiseptics and asepsis, have revolutionized nursing in the home, the hospital and the Poor Law infirmary. The nurse is now looked upon as following a great vocation for which she has to be qualified by years of training.

GREAT BRITAIN

Training of Nurses.—In Great Britain the training of the nurse is regulated by the state through the Nurses' Registration Act of 1919. This act was only carried into law after years of controversy, ending with the War. There is a general nursing council for England and Wales and another for Scotland, and 16 of the 25 members of the English council must be registered nurses elected by persons registered under the act.

In addition to the ordinary registration of nurses with a general training (which occupies three or four years) there are five supplementary registers for male, mental, fever, mental defectives' and sick children's nurses. Nurses usually begin their general training in recognized training schools at an age not less than 21, though for certain kinds of training (such as those for nurses of fever or sick children) probationers are taken earlier. The nurses usually live in the hospital or in hostels near it; and as a rule, those who remain in hospital retire about the age of 50 or 55, when a pension is frequently provided with or without contribution. Post-graduate teaching is developed in the best schools, as is the system of providing tutor-nurses. There is not as yet much connection with the universities though the University of Leeds grants a diploma in nursing. The matron of a great hospital holds a very important position as regards her staff, which is divided into sisters, staff nurses and probationers. There are specialists in electric and other technical work, but these have usually first completed their general training. Strenuous efforts have been made to reduce the hours of service and to increase the salaries, which for many years have been extremely low.

In 1916 a college of nursing was established and in 1925 it had a membership of 24,000 with 42 branches and sub-branches throughout the United Kingdom. Connected with it are a student nurses' association for nurses in training, a section for sister tutors and a section for public health workers. It is recognized by the Ministry of Health as an approved centre for the training of health visitors.

Although a large number of nurses serve in hospitals, these are regarded mainly as training schools, where the young nurse is carrying on her studies as well as gaining practical experience. The difficulty with the present hours of duty is to provide the necessary time for her studies and for preparing for frequent examinations, state and hospital. In early days, the importance of the training was not fully recognized, and the nurse was regarded as one who simply performed certain useful functions. Now, the doctor or surgeon looks to the nurse for assistance in his work; he can only see the patient at intervals but she has him always under observation, and the accuracy of her report is of vital importance.

District Nurses. On completing her general training, usually of four years, a nurse may take her district training and be placed on the roll of the Queen's nurses, which are supervised from headquarters but supported locally. There are still "cottage nurses," with a short training, but those with a higher standard are rapidly increasing, more especially as they are eligible to do county health

work under the medical officer of health. Those holding the certificate of the Central Midwives Board are often employed in infant and child-welfare work.

Public Health Work. In addition to child welfare work many nurses are employed under county, burgh or city schemes. The education authorities require a large staff for following up the cases of children inspected by their medical officers. Nurses are also required for fever and isolation hospitals. Poor Law infirmaries give excellent training and have certain advantages over hospitals, which are also schools for the medical profession.

Private Nursing. This form of nursing has expanded enormously and though some visiting nurses come in for the day they are mainly residential. Nurses who undertake this work are to be had either from a hospital which sends out its nurses after they gain their certificates, or from an institution, possibly a co-operative institution or home. Nurses are employed in many private nursing-homes for the well-to-do.

Mental Nurses. The training for mental nurses is usually conducted in a recognized institution for the treatment of mental disorders where the candidate serves for three years, and enters for the state examination for mental nurses. The nurses and attendants are of both sexes, but women are being increasingly employed even for male patients.

Midwives and Maternity Nurses. Midwifery is controlled by a Central Midwives Board, established in London, with jurisdiction in England and Wales, and there are separate boards for Scotland and Ireland. The number of midwives on the roll in England and Wales is approximately 78,000. These boards regulate the issue of certificates and the conditions of admission, and have also the power to remove names from the roll. In 1910 it was forbidden to any person to attend women in childbirth for gain (otherwise than under direction of a qualified medical practitioner) unless certified under the act. An incorporated Midwives Institute has done splendid work in promoting the interests of midwives. Many trained nurses take the midwives' certificate, for which a six months' special course is required while a twelve months' course of midwifery is necessary for those who are not trained nurses.

Masseurs and Masseuses. The Chartered Society of Massage and Medical Gymnastics grants a certificate to those who have taken a prescribed training at a recognized school and have passed an examination. After June 1927, examination on massage ceased as a single subject.

Various Services. A voluntary advisory nursing board was established in 1921 under the Prison Commission of the Home Office, and trained nurses are now appointed for the care of sick prisoners. A nursing service deals with hospitals under the Ministry of Pensions, and a matron-in-chief is at its head.

The Overseas Nursing Association sends trained nurses to the Crown Colonies and small British communities abroad. There is also an Indian nursing service for Europeans in India.

Queen Alexandra's Imperial Military Nursing Service originated in 1902. A nursing board advises the secretary of state on matters connected with the service. A matron-in-chief is at its head and principal matrons, matrons, sisters and staff nurses are subordinate to her.

In the first year of the World War there were 2,323 fully trained reserve nurses in addition to the regular service, and by 1918 the number reached 10,304. There is likewise a service called Queen Alexandra's Military Families Nursing Service. The Territorial Army Nursing Service, established in 1907-8 in connection with the Territorial Army, supplied the largest number of British nurses available on the outbreak of the World War. The probable number required is about 4,000, but the territorial nurses are only called up in case of necessity. Like the Territorial Army, they enroll with overseas obligations.

Queen Alexandra's Royal Naval Nursing Service is a small one, which also has a reserve. The Royal Air Force Nursing Service was established in 1921. (See MEDICAL SERVICE, ARMY.)

(E. S. H.)

UNITED STATES

Nursing in the United States under the Nightingale plan,

according to which student nurses are educated by nurses as well as by physicians, began in 1873 at the Bellevue Hospital, New York, the Connecticut Training School, New Haven, and the Massachusetts General Hospital, Boston. Mention of it, however, is made earlier in connection with care of the sick in the Pennsylvania Hospital, the charter of which was granted in 1751, the New York Hospital in 1798, the Philadelphia Dispensary in 1855 and the New England Hospital for Women and Children in 1859-60.

Training generally begins at 18, though in some hospitals the minimum entrance age is 19, 20 or 21. Under the apprenticeship system, making of a hospital and school of nursing not two separate institutions but one and the same, the nursing in the wards is done by these young students in most of the hospitals where they are trained. Of the 7,416 hospitals in 1927, 5,261 were very small or State institutions without schools and in 75% of the remaining 2,155 the nursing was done by students in most schools without the assistance of a single general-duty graduate nurse. After from one to four years training nurses pass out into professional life at the average yearly rate of approximately 18,000.

Each State has a board of nurse examiners with which properly accredited nurses may register after passing an examination. On Jan. 1, 1928, there were 200,000 registered nurses in the United States. Of the various branches of nursing 54% go into private duty, 19% into public health, and 23% into institutional work but they change from field to field, especially away from private duty with its uncertainty of employment and its demand for 24-hour duty arising from the fact that many families are unable to afford a night nurse as well as a day nurse in sickness.

A field for nurses developed generally in 1905 when the Massachusetts General Hospital, Boston, instituted hospital social service. The idea originated in 1879 when the Ethical Culture Society of New York employed a nurse with a visiting physician in connection with the dispensary. It means follow-up work among discharged patients and their families, carrying the treatment of the hospital into the home and utilizing the opportunity of education, systematizing and co-ordinating treatment with rehabilitation of the family through public and private agencies. Staffs of social workers and nurses are now employed for this purpose.

The usual yearly salary of the typical private duty nurse throughout her professional life was computed in 1928 to be \$1,311 since the months of employment average but 7 out of 12; public health nurses begin at about \$1,450, with the yearly average \$1,720; and nurses in institutions begin at \$1,750 plus maintenance, with the yearly average \$2,079 plus maintenance. The superintendent of a hospital receives an average salary of \$2,600 to \$2,700; the superintendent of nurses of \$2,500 to \$2,600 plus maintenance; and the superintendent of hospital and nurses jointly an average of \$2,400 to \$2,500 plus maintenance. Nurses in the United States are recruited largely from the agricultural, manufacturing, trade and professional classes with proportionately more from the last group than from the first, considering the extent of agricultural pursuits in the country.

As a profession, nurses in the United States are organized into three national organizations for which they themselves are responsible, the American Nurses Association, the National Organization for Public Health Nursing and the National League of Nursing Education. Each organization has its individual staff of full-time workers engaged in promoting the various aspects of nursing interests. The remarkable progress made in the nursing field in the past 30 years is due to the distinctive service rendered by these national organizations because of their specialized knowledge and experience and steadfast insistence on the maintenance of the highest standards.

Government Nursing Services.—The Army Nursing Service was established by Act of Congress in 1901 and the Navy Nursing Service in 1908. The Army School of Nursing, Washington, D.C., was established on progressive lines in 1918 with hospital affiliations to give its students the experience necessary for complete training. The U.S. Public Health Service employs a staff of nurses under a woman superintendent to assist in carrying out its extensive public health programme in hospitals, in foreign and domestic quarantine and various sanitation projects. The U.S.

Veterans' Bureau nursing service also has a woman superintendent who is a registered nurse. It is now (1928) the largest of the Government nursing services and is composed of two groups of nurses, those who care for the patients in the nation-wide chain of Veterans' Bureau hospitals and those who do welfare work among the ex-service men in their homes. The U.S. Government has a great nursing reserve upon which it can draw in time of need in the American Red Cross Nursing Service (see AMERICAN RED CROSS) which has been closely linked with the American Nurses Association throughout its history, and membership in this association is essential to enrollment, as an insurance of standards. NUSKU, personification of the new-moon, the name of the light and fire-god in Sumer, Babylonia and Assyria, who is hardly to be distinguished from a god Gibil. Nusku-Gibil is the symbol of the heavenly as well as of the terrestrial fire. As the former he is the son of Anu, the god of heaven, but he is likewise associated with Enlil of Nippur, the earth god, and regarded as his messenger. A centre of his cult in Assyria was in Harran, where, because of the predominating character of the moon-cult, he is viewed as the son of the moon-god Sin (*q.v.*). He is often called upon to cleanse the sick and suffering in the magic fire rituals.

The fire-god is also viewed as the patron of the arts and the god of civilization in general, because of the natural association of all human progress with the discovery and use of fire, and as the protector of the family. He becomes the mediator between humanity and the gods, since it is through the fire on the altar that the offering is brought into the presence of the gods.

While temples and sanctuaries to Nusku-Gibil are found in Babylonia and Assyria, he is worshipped more in symbolism than the other gods. Nusku and Gibil are symbolized by the lamp.

See A. Deimel, *Pantheon Babylonicum*, Nos. 598 and 2367. H. Zimmern, *Kellinschriften und das Alte Testament*, 416-420.

NUT, a term applied to that class of fruit which consists generally of a single kernel enclosed in a hard shell. Botanically speaking, nuts are one-celled fruits with hardened pericarps, sometimes enveloped in a cupule or cup, formed by the aggregation of the bracts as in the hazel and the acorn. A great number of nuts enter into commerce for various purposes, principally as articles of food or sources of oil, and for several ornamental and useful purposes. The edible nuts are very rich in oil, with a small percentage of the other carbohydrates, starch, sugar, etc., and also a large proportion of nitrogenous constituents. Oleaginous nuts used for food are likewise employed more or less as sources of oil, but on the other hand there are many oil-nuts of commercial importance not embraced in the list of edible nuts.

On the following page is set out an alphabetical enumeration of the more important nuts, and of products passing under that name, used either as articles of food or as sources of oil.

There remain to be enumerated a number of nuts of commercial value for turnery and ornamental purposes, for medicinal use, and for several miscellaneous applications in the arts. See table at foot of p. 646.

The application of the term nut to many of these products is purely arbitrary, and it is obvious that numerous other bodies

Name	Source	Locality	Remarks
Almond	<i>Prunus Amygdalus</i> , var. <i>dulcis</i>	S. Europe	Food, oil.
Almond (bitter)	<i>Prunus Amygdalus</i> , var. <i>amara</i>		Oil.
Ar nut or earth nut	Tubers of <i>Bunium flexuosum</i> and other species	W. Europe (Britain)	Food.
Bambarra ground nut	<i>Voandzeia subterranea</i>	Tropics, especially Africa	Food.
Ben nut	<i>Moringa oleifera</i> (a winged seed)	India	Oil.
Bitter nut	<i>Carya cordiformis</i> (swamp hickory)	N. America	See HICKORY.
Brazil nut	<i>Bertholletia excelsa</i>	S. America	Food, oil.
Bread nut	<i>Brosimum Alicastrum</i>	W. Indies	Food.
Butter or Souari nut	<i>Caryocar nuciferum</i>	Guiana	Food.
Cahoun nut	<i>Attalea Cohune</i>	Honduras	Oil.
Candle nut	<i>Aleurites triloba</i>	S. Sea Islands	Oil.
Cashew nut	<i>Anacardium occidentale</i>	W. Indies and Tropical America	Food, oil.
Chestnut	<i>Castanea vesca</i>	S. Europe	Food.
Cob, filbert, or hazel	<i>Corylus avellana</i>	Europe (Britain), etc.	See HAZEL.
Cob nut of Jamaica	<i>Omphalea diandra</i>	W. Indies and Tropical America	Food.
Coco-nut	<i>Cocos nucifera</i>	Tropics	Food, oil.
Cola nut	<i>Cola vera</i>	W. Africa	Food.
Dika nut	<i>Irovingia Barteri</i>	W. Africa	Food, oil.
Ginkgo nut	<i>Ginkgo biloba</i> (seed)	Japan, China	Food, oil.
Hickory nut	<i>Carya ovata</i>	N. America	See HICKORY.
Hog nut	<i>Carya glabra</i>	N. America	Eaten by animals.
Jesuit's nut	<i>Trapa natans</i>	S. Europe	Food.
Mocker nut	<i>Carya alba glabra</i>	N. America	See HICKORY.
Moreton bay chestnut	<i>Castanospermum australe</i>	Australia	Food.
Nutmeg	<i>Myristica fragrans</i>	E. Indies	Spice. See NUTMEG.
Nutmeg (wild)	<i>Myristica fatua</i> , <i>M. tomentosa</i> , etc.	Tropics	Spice. See NUTMEG.
Olive nut	<i>Eleocarpus Ganitrus</i> , etc.	E. Indies	Food.
Palm nut	<i>Elais guineensis</i>	W. Africa	Oil. See PALM.
Pea nut	<i>Arachis hypogaea</i>	Tropics	See PEA NUT.
Pecan nut	<i>Carya Pecan</i>	N. America	Food, oil. See HICKORY.
Pekoa nut	<i>Caryocar butyrosom</i>	Guiana	Food.
Physic nut	<i>Jatropha Curcas</i>	Tropical America	Oil.
Pine nut	<i>Pinus Pineae</i> , etc.	Italy	Food.
Pistachio nut	<i>Pistacia vera</i>	S. Europe, etc.	Food.
Quandang nut	<i>Fusanus acuminatus</i>	Australia	Food.
Ravensara nut	<i>Ravensara aromatica</i>	Madagascar	Spice.
Rush nut	<i>Cyperus esculentus</i> (tubers)	S. Europe, etc.	Food.
Sapucaia nut	<i>Lecythis Ollaria</i>	Brazil	Food.
Tahiti chestnut	<i>Inocarpus edulis</i>	S. Sea Islands	Food.
Walnut	<i>Juglans regia</i>	Asia, Europe	Food, oil.
Water chestnut	Species of <i>Trapa</i>	S. Europe, India, etc.	Food.

not known commercially as nuts might with equal propriety be included in the list. Most of the nuts of real commercial importance receive separate notice, and here further allusion is only made to a few which form current articles of commerce, not otherwise treated of.

The bread nut of Jamaica is the fruit of a lofty tree, *Brosimum Alicastrum*. It is about an inch in diameter, and encloses a single seed, which, roasted or boiled, is a pleasant and nutritious article of food.

The souari or surahwa nut, called also the "butter nut of Demerara," and by fruiterers the "suwarrow nut," is the fruit of *Caryocar nuciferum*, a native of the forests of Guiana, growing 80 ft. in height. This is perhaps the finest of all the fruits called nuts. The kernel is large, soft, and even sweeter than the almond, which it somewhat resembles in taste. The few that are imported come from Demerara, and are about the size of an egg, somewhat

kidney-shaped, of a rich reddish-brown colour, and covered with large rounded tubercles.

Cola, kola or goora nuts are the seeds of *Cola vera* (Sterculiaceae), a tree, native of tropical Africa, now introduced into the West Indies and South America. The nuts form an important article of commerce throughout central Africa, being used over a wide area as a kind of stimulant condiment. The nuts, of which there are numerous varieties, are found to contain a notable proportion of caffeine, as much as 2.13%, besides theobromine and other important food-constituents, to which their valuable properties are due.

Coquilla nuts, the hard inner portion ("stone") of the palm, *Attalea funifera*, the piassaba of Brazil, are highly valued for turnery purposes. They have an elongated oval form, 3 to 4 in. in length, and being intensely hard they take a fine polish, displaying a richly streaked brown colour.

Name	Source	Locality	Remarks
Betel nut	<i>Areca Catechu</i>	E. Indies	
Bladder nut	<i>Staphylea pinnata</i>	S. Europe	Nocklaces.
Boamah nut	<i>Pycnocomia macrophylla</i>	Africa	Tanning.
Bonduc nut	<i>Caesalpinia Bonduc</i>	India	Medicine, beads.
Clearing nut	<i>Strychnos potatorum</i>	India	Clearing dirty water.
Coquilla nut	<i>Attalea funifera</i>	Brazil	Turnery.
Corozo nut or vegetable ivory	<i>Phytelephas macrocarpa</i>	Tropical S. America	See PALM.
Cumara nut (Tonka or Tonquin bean)	<i>Dipteryx odorata</i>	Tropical S. America	Perfume.
Grugru nut	<i>Acrocomia tatarocarpa</i>	S. America	Beads.
Horse chestnut	<i>Aesculus Hippocastanum</i>	S. Europe	Starch.
Marking nut	<i>Semecarpus Anacardium</i>	E. Indies	Marking ink and varnish.
"Nut" galls	<i>Quercus galls</i>	Levant	Dyeing and ink making. See GALLS.
Poison nut	<i>Strychnos Nux-Vomica</i>	E. Indies	Medicine. See NUX VOMICA.
Sassafras nut	<i>Nectandra Puchury</i>	S. America	Aromatic.
Snake nut	<i>Ophiocaryon paradoxum</i>	S. America	Curiosity.
Soap nut	<i>Sapindus Saponaria</i>	W. Indies	Washing; ornamental.

VARIOUS KINDS OF COMMERCIAL AND EDIBLE NUTS

READ FROM TOP TO BOTTOM

1. Peanut; half of shell removed exposing, left, kernel, and right, kernel enclosed in skin; two whole kernels
2. Pistachio nut; half of shell removed showing kernel; kernel removed from shell
3. Brazil nut; whole kernel
4. Walnut kernel; whole walnut; shell broken to expose part of kernel
5. Pecan kernel; whole pecan nut; shell broken showing kernel
6. Almond kernel; whole almond; shell broken showing part of kernel
7. Filbert kernel; whole filbert; part of shell removed to show kernel

The marking nut, *Semecarpus Anacardium*, is a fruit closely allied in its source and properties to the cashew nut (*q.v.*). The marking nut is a native of the East Indies, where the extremely acrid juice of the shell of the fruit in its unripe state is mixed with quicklime and used as a marking-ink. The juice when dry is the basis of a valuable caulking material and black varnish. The seeds are edible, and the source of a useful oil.

Physic nuts are the produce of the euphorbiaceous tree, *Jatropha Curcas*, whence a valuable oil, having similar purgative properties to castor oil, is obtained. The plant is a native of South America, but is found in all tropical countries.

Pine nuts are the seeds of several species of *Pinus*, eaten in the countries of their growth, and also serving to some extent as sources of oil. Of these the most important are the stone pine, *Pinus Pinea*, of Italy and the Mediterranean coasts, and the Russian stone pine, *Pinus Cembra*. *Pinus Sabiniana*, the digger pine of California; *P. edulis*, *P. monophylla*, *P. Parryana*, and *P. cembroides*, the "piñons" of the southwestern United States and northern Mexico; and also *P. Gerardiana* of the Himalayas similarly yield edible seeds. These seeds possess a pleasant, slightly resinous flavour.

Ravensara nuts, the fruit of *Ravensara aromatica* (Lauraceae), a native of Madagascar, is used as a spice under the name of the Madagascar clove nutmeg.

The Sapucaia nut is produced by a large tree, *Lecythis Ollaria*. Its specific name is taken from the large urn-shaped capsules, called "monkey-pots" by the inhabitants, which contain the nuts. The sapucaia nut has a sweet flavour, resembling the almond, and is of a rich amber-brown; not unlike the Brazil nut.

Soap nuts are the fruits of various species of *Sapindus*, especially *S. saponaria*, natives of tropical regions. They are so called because their rind or outer covering contains saponin, which lathers in water, and so is useful in washing.

NUT: For the nut in engineering, etc., see **BOLT**.

NUTATION [from Lat. *nutare*, to nod], a deviation of the celestial pole from its mean position, due to inequalities in the action of the sun and moon on the equatorial protuberance of the earth. The main part of the nutation is a motion of the pole in a circle of 9" radius in a period of 18.6 years. See **PRECESSION OF THE EQUINOXES**.

The name is also used in reference to the phenomena of certain organs in plants which bend alternately in opposite directions. In some cases the apex of the stem will describe a spiral movement, inclining to all points of the compass in succession; this being termed *circumnutation*. See **PLANTS**.

NUTCRACKER (*Nucifraga caryocatactes*), an European bird of the crow family (*Corvidae*). The plumage is mottled and the tail feathers have conspicuous white tips. The beak is long and the flight undulating. The nutcracker feeds mainly on conifer seeds, but also takes fruits, insects and young birds. The nest is built on the bough of a tree, about 20 ft. from the ground, and is a large structure of sticks lined with grass. The eggs are of a very pale bluish-green, freckled with pale olive or ash colour. Another species (*N. columbiana*) is found in America.

The Siberian nutcracker migrates into western Europe in large flocks, at intervals of approximately 11 years. See also **CROW**.

NUT CULTURE IN THE UNITED STATES. The United States is especially rich in native nut-bearing trees, as the black walnut, butternut, chestnut, hazel and various hickories, and contains large districts in which the soil and climate are suitable for nut production. Recent experimental cultivation of numerous varieties of native as well as introduced species has yielded very promising results. As yet, however, the culture of only three kinds of nut-bearing trees has been established on a substantial commercial basis and attained rank as a horticultural industry. Of these, the pecan (*Carya Pecan*), a species of hickory (*q.v.*), is a native tree brought into extensive cultivation only since 1900, while the others, the Persian walnut (*Juglans regia*) and the almond (*Prunus Amygdalus*) are Old World trees that have been grown widely since ancient times.

Numerous varieties of the pecan are planted for commercial production in the Southern States. Hardy strains are producing

successfully in Missouri, Illinois and Indiana, indicating the probable extension of pecan culture throughout the central Corn Belt (*q.v.*). In 1926, which was a maximum crop year, the total production was estimated by the U. S. Department of Agriculture at 64,046,000 lb., valued at \$9,772,000. The yearly average for the four-year period 1924-27 inclusive was 33,854,500 lb., with an average annual value of \$6,506,000.

The commercial production of almonds is restricted to various forms of the sweet variety (var. *dulcis*), with increasing preference for those having thinner walls in the stone, as in the paper-shell almonds. The climatically suitable districts are comparatively limited, being confined chiefly to the Pacific States. In California, which usually grows about 99% of the United States crop, the production of sweet almonds in 1926 was estimated at 16,000,000 lb., valued at \$4,800,000.

The commercial production of the Old World or Persian walnut, in the United States often called English walnut, has attained its greatest development in specially selected and prepared soils under irrigation in California. However, hardy strains are grown locally with considerable success in the eastern States from Massachusetts westward and southward to Arkansas, especially in climatic situations similar to the Great Lakes region of western New York. In California, where about 98% of the American commercial crop is grown, the production of walnuts in 1927 was estimated at 84,000,000 lb., valued at \$15,120,000.

NUTHATCH, a small bird, so called from its habit of hacking nuts, which it cleverly fixes in a crevice of the bark of a tree, and then hammers with the point of its bill till the shell is broken. This bird is known as *Sitta Caesia*. It is not normally found in Ireland or Scotland. Without being plentiful anywhere, it is generally distributed in localities which afford it a sufficient supply of food, consisting during the greater part of the year of insects, which it seeks on limbs of trees; but in autumn and winter it feeds on nuts, beech-mast, the stones of yew-berries and hard seeds.

It generally makes its nest in a hollow branch, plastering up the opening with clay, leaving only a circular hole just large enough to afford entrance and exit; the interior is made of a bed of dry leaves or flakes of the inner bark of a fir, on which the eggs are laid. In the Levant another species (*S. syriaca*) haunts rocks rather than trees; and four or five arboreal species are found in North Asia. North America possesses four species: *S. canadensis* has the most northern range, while the white-bellied *S. carolinensis* inhabits more southern latitudes. Related genera, found in the Indian region, are remarkable for their beautiful blue plumage. Other genera occur in Madagascar, Australia and New Guinea. The nuthatches are placed in the passerine family *Sittidae*.

NUTKA. This people held the west coast of Vancouver island, and with the Makah of Cape Flattery form one branch of the Wakashan family, the Kwakiutl constituting the other. The speech relationship of Nutka and Kwakiutl is not close, and the two bodies must have been distinct a long time. Nutka culture is that of the North Pacific coast, with specializations, such as whale hunting, that reflect frontage on the open ocean. Their trade influence is shown by the considerable proportion of words they contributed to the composite Chinook jargon. (See G. M. Sproat, *Scenes of Savage Life*, 1868.)

NUTLEY, a town of Essex county, New Jersey, U.S.A., on the Passaic river, 7 m. N. of Newark, adjoining Belleville and Bloomfield. It is served by the Erie railroad and motor-coach lines. There are paper, silk, woollen mills and several other factories, but the town is primarily a suburban residential community. Pop. (1920) 9,421; 1928 local estimate 20,000.

NUTMEG, the commercial name of a spice representing the kernel of the seed of *Myristica fragrans*, a dioecious evergreen tree, about 50 to 60 ft. high, found wild in the Molucca islands and extending to New Guinea. Nutmeg and mace are mostly obtained from the Molucca islands, although the cultivation has been attempted with varying success in Singapore, Penang, Bengal, Réunion, Brazil, French Guiana and the West Indies. The trees yield fruit in eight years after sowing the seed, reach their prime in 25 years, and bear for 60 years or longer. Almost the whole surface of the Molucca islands is planted with nutmeg trees,

which thrive under the shade of the lofty *Canarium commune*. The ripe fruit is about 2 in. in diameter, of a rounded pear-shape, and when mature splits into two, exposing a crimson arillus surrounding a single seed. When the fruit is collected the pericarp is first removed; then the arillus is carefully stripped off and dried, in which state it forms the mace of commerce. The seed consists

NUTMEG (*MYRISTICA FRAGRANS*). SHOWING (A) SEED WITH CARIL (MACE) ROUND IT; (B) BRANCH SHOWING RIPE FRUITS, ONE OF WHICH IS SPLITTING AND SHOWS SEED INSIDE; (C) TWIG WITH FLOWERS

of a thin, hard shell, enclosing a wrinkled kernel, which, when dried, is the nutmeg.

To prepare the nutmegs for use, the seed enclosing the kernel is dried at a gentle heat in a drying-house over a smouldering fire, the seeds being turned every second or third day. When thoroughly dried the shells are broken and the nutmegs picked out and sorted, the smaller and inferior ones being reserved for the expression of the fixed oil which they contain, and which forms the so-called oil of mace.

"Oil of mace," or nutmeg butter, is a solid fatty substance of a reddish-brown colour, obtained by grinding the refuse nutmegs to a fine powder, steaming it and then compressing it while still warm. The brownish fluid which flows out being afterwards allowed to solidify. Nutmegs yield about one-fourth of their weight of this substance. It is partly dissolved by cold alcohol, the remainder being soluble in ether. The latter portion, about 10% of the weight of the nutmegs, consists chiefly of *myristin*, which is a compound of *myristic acid*, $C_{14}H_{28}O_2$, with glycerin.

The name nutmeg is also applied to other fruits or seeds in different countries. The Jamaica or calabash nutmeg is derived from *Monodora Myristica*, the Brazilian from *Cryptocarya moschata*, the Peruvian from *Laurelia sempervirens*, the Madagascar or clove nutmeg from *Agathophyllum aromaticum*, and the Californian or stinking nutmeg from *Torreya californica*.

NUTRITION. Despite the fact that life may be continued for many weeks without food and for several days without water, for the practical maintenance of life we must have a regular intake of food; nutrition must go on. Food is required for two main purposes: (1) to supply the necessary energy for the production of internal and external work and the maintenance of the body temperature and (2) to supply the necessary material to make good the wear and tear of the tissues in the adult and also, especially in the child, the material required for growth. The study of the problem of nutrition demands therefore the study of the methods by which the various foodstuffs are digested, absorbed and utilized in the body and further how the waste products formed during the various tissue activities are got rid of.

The evidence available would seem to point to the fact that the majority of mankind eat too much rather than too little. Excessive intake may prove to be, probably is, harmful. Certain experiments carried out for purely commercial purposes on the breeding of pelt-bearing animals go to show that such animals do best on a diet just slightly in excess of the bare maintenance ration. (See DIET AND DIETETICS.)

CHEMISTRY OF DIGESTION

The essential step which prepares the ordinary food for utilization in the body, for the change into living matter, is digestion, a process which the food undergoes under the influence of the ferments or enzymes present in the gastro-intestinal tract. By this process it is broken down into simpler substances, which can be utilized by the body tissues for conversion into protoplasm and as the supply of energy.

Enzyme Action in General.—The substances which bring about this change are known as ferments, enzymes or zymins. Formerly it was believed that there were two distinct classes of enzymes: those which were living or associated with living cells, and those which were non-living. In 1897, however, E. Buchner and M. Hahn showed that from living cells (yeast) a ferment could be obtained which acted quite as well extracellularly as when it was bound up within the cell. Subsequent work has shown that other organisms act by the enzymes they contain, so that it is now recognized that there is no essential difference between the living or organized ferment and the non-living or unorganized ferment. All ferments probably act as catalysts. Catalysis (*q.v.*) is the process by which reactions are either initiated or accelerated by the mere presence of certain substances which remain unchanged during the process. It has been shown that the action of ferments is specific; *i.e.*, the ferment only exerts its action on definite substances or substrates of definite structural arrangement. The relation of ferment to substrate has been compared to that of a key to its lock. Ferments which bring about the breakdown of proteins are without influence on fats and carbohydrates; those which decompose fats leave proteins and carbohydrates untouched, and so on.

The chemical composition of enzymes is unknown, but it would seem certain that all enzymes have not the same chemical structure. One of their most important physical properties is their colloidal nature, shown by the fact that they cannot, or only with extreme difficulty, pass through a parchment membrane.

Most of the ferments are soluble in water or saline solutions, and in glycerol and water. The ferments are found to have an optimum temperature of action. This temperature in most cases ranges from 37° to 40° C. All true ferments are thermolabile, being destroyed at about 70° C. The action of many of them is retarded when the products of their action are allowed to accumulate. Just as when a chemical reaction is set up its rate tends to decrease and finally comes to a standstill before the reaction is completed—an equilibrium being established—so the reactions set up by enzymes also tend to come to an equilibrium before the complete conversion of the original substance.

A number of the body ferments have now been shown to exist in the tissues in an inactive form. This condition is known as the proferment or zymogen state, and before any action can be exerted it must be activated, usually by some specific substance, as in the case of the activation of trypsinogen by means of enterokinase. The table on page 649 gives a list of the principal ferments concerned in the digestion and metabolism of food-stuffs.

Certain oxydases, catalases and de-aminizing enzymes are found in the tissues generally and play an important part in the various metabolic processes.

Digestion in the Mouth.—The first of the digestive secretions which food encounters is the saliva. It is produced by the three large salivary glands, the parotid, the sub-maxillary and the sub-lingual, is a colourless or slightly turbid viscous fluid with a faintly alkaline reaction and of low specific gravity, and exercises a twofold function. First, it has a mechanical action moistening the mouth and the food and thus aiding mastication and swallowing by securing the formation of a proper bolus

Material acted on	Enzyme	Where found
I. Protein . . .	Pepsin	Gastric juice
	Trypsin	Pancreatic juice
	Erepsin	Small intestine
II. Fats . . .	Various auto-lytic enzymes	Tissues generally
	Lipase	Pancreatic juice and certain tissues
III. Carbohydrates	Ptyalin (salivary diastase)	Saliva
	Pancreatic diastase	Pancreatic juice
	Maltase	Pancreatic juice
	Invertase	Small intestine
	Lactase	Small intestine
	Various tissue diastases	Liver, muscle, etc.

of food; it also assists by binding the particles together, an action of special importance when the food is dry. Second, in man and in some of the lower animals the enzyme ptyalin exerts an action in digestion on part of the carbohydrates of the diet. The starches or polysaccharides are broken down, first of all to the simple dextrans and then to the still more simple disaccharide, maltose. The action of ptyalin on starches is thus very similar to that of acids, except that it stops at the formation of maltose. Ptyalin acts best at a temperature of about 40°C and in a neutral or faintly alkaline medium, its action being inhibited by the presence of even very dilute solutions of the mineral acids. If the acid be in sufficient amount the enzyme is destroyed. For this reason the action ceases in the stomach whenever the bolus is completely permeated by the gastric juice. As it takes time for the gastric juice thoroughly to permeate the food mass, which remains for a considerable period in the fundus of the stomach unmixed with the secretion, salivary digestion goes on for about half an hour after food is taken.

Gastric Digestion.—The stomach has two digestive functions: (i.) it acts as a store chamber permitting a full meal to be taken; (ii.) it acts as a digestive organ of importance in preparing the food for further attack in the intestinal canal. But the stomach cannot be regarded as an essential organ, since it has been removed in dogs and in man without apparent interference with health.

Gastric digestion is brought about by the action of the gastric juice, a clear watery, colourless and strongly acid fluid with a specific gravity of about 1.003. The amount of hydrochloric acid present in the juice varies with the period of digestion. The acid exists in the stomach in two forms, as free hydrochloric acid and as combined hydrochloric acid. The amount of each depends on various factors: (i) the secretion itself; (ii.) the nature of the food; and (iii.) the rapidity with which the stomach empties itself, etc. For instance, after a protein-free meal the hydrochloric acid is for the most part free, whereas, when protein is present, it combines with it and, unless secreted in very large amount, most of the acid is in a fixed condition.

The hydrochloric acid is formed by the activities of certain gland cells in the middle region of the stomach, and the fact that it does not exist as such in the blood proves that it is formed within these cells. That the chlorine comes from the sodium chloride in the food has been shown by the fact that, when the tissues are deprived of this salt, and sodium bromide is given, hydrobromic acid may appear in the gastric secretion.

The hydrochloric acid is essential for the action of the gastric enzyme, pepsin, in splitting up the protein of the food. In addition to this, the acid has a slight action in splitting polysaccharides and disaccharides. Lastly, it acts as a bactericidal agent, preventing bacterial decomposition from taking place, and it may thus prevent certain noxious bacteria, taken in in the food, from gaining access to the intestinal tract, where there is a chance of their flourishing in the rich alkaline medium.

The quantity of juice secreted varies with the nature of the food consumed. Each separate food seems to give rise to a definite hourly secretion of the juice and to a characteristic alteration in its properties.

The principal ferment found in the gastric juice is pepsin,

which acts only in the presence of a mineral acid. The action proceeds best at a temperature of about 37°C in an acid medium of 0.2% to 0.3%. Pepsin is elaborated in the so-called chief cells of the gastric glands as an inert precursor—propepsin. It is only when it comes into contact with the acid of the juice that it is activated into attacking the protein of the food.

As already mentioned, the main function of the gastric juice is to deal with the protein moiety of the food and to prepare it for further digestion in the intestine. The first result of the action of this secretion on protein matter is to render it soluble—a metaprotein or acid albumin being formed. This body may be regarded mainly as the product of the action of the hydrochloric acid independently of the pepsin.

The following steps of decomposition are the result of the action of pepsin. From the metaprotein primary and secondary proteoses are formed, and from these peptones are finally produced. The result of this process of digestion or hydrolysis induced by the pepsin is that complex insoluble protein substances of high molecular weight are converted into simpler soluble protein bodies of comparatively low molecular weight. The contents of the stomach—products of protein digestion—are passed on into the duodenum, chiefly as proteoses and peptones.

In addition to pepsin some workers hold that another enzyme is present in the gastric juice. This is the ferment rennet, rennin or chymosin, the sole action of which, so far as is known at present, is to bring about the curdling of milk, the curd formed being subsequently dealt with in the ordinary way by the pepsin. Clotting of milk under the action of rennin occurs at a suitable temperature with great rapidity. This process is said to take place in two stages: (1) the rennin converts the caseinogen of the milk into soluble casein, and (2) this soluble casein unites with the lime salts present in the milk and forms the curd or precipitate. That lime salts are absolutely essential for this process of clotting has been shown by the fact that, if they are removed by precipitation as by oxalates, no clotting will take place even after the addition of a large amount of active rennin. Immediate clotting takes place, however, when the necessary lime salts are restored.

The speed with which the stomach empties itself depends to a great extent on the nature of the food. Plain water leaves the stomach almost at once, salt and sugar solutions at a somewhat slower rate. On a mixed diet, emptying of the stomach in man proceeds very slowly, requiring about four hours. Cannon, by feeding with food impregnated with bismuth and using X-rays, showed that carbohydrates leave most rapidly, then mixtures of carbohydrates and proteins, then proteins, then fats and finally mixtures of fats and proteins. The diet which remains longest in the stomach is a mixture of fats and proteins—rich food, as it is popularly called. Here two factors enter to prevent rapid emptying: (1) the presence of much fat, and (2) the acid secretion engendered by the abundant protein.

There is no doubt that fats present in fine emulsion can be decomposed in the stomach. The action proceeds in a medium which is slightly acid or neutral, being entirely prevented by the presence of strong acids and alkalis. Many workers believe this gastrolipase to be of pancreatic or intestinal origin, and suppose that it gains entrance to the stomach by a reflux flow through the pylorus.

No specific enzyme for carbohydrates has been found in the stomach in man. Certainly a small amount of polysaccharide decomposition takes place, but this is dependent (1) on the ptyalin which comes from the mouth, and (2) on a certain amount of hydrolysis due to the action of the free hydrochloric acid.

Digestion in the Intestine.—The food so far digested in the stomach is known as chyme, and it is passed on to undergo intestinal digestion under the influence of (1) the enzymes of the pancreas, and (2) of other enzymes present in the different secretions of the intestine.

Pancreatic Digestion. The pancreatic juice is the secretion from the pancreas and is discharged into the duodenum. It is a clear, usually thin fluid with a specific gravity of about 1.008, and with an alkaline reaction. The most important inorganic constit-

uent is sodium carbonate, which gives the alkaline reaction. This alkaline salt, along with that contained in the intestinal juice, plays an important part in neutralizing the acid chyme.

In the pancreatic secretion there are at least three important enzymes, each with a definite action: (a) trypsin, the proteolytic enzyme which brings about the further breakdown of the food proteins; (b) a diastase which deals with the carbohydrates, and (c) a lipase which acts on the fats.

(a) *Trypsin*. This ferment, in the form in which it is secreted—trypsinogen—is inert. Before it can exert its hydrolytic action it must be activated. This activation is brought about by another enzyme found in the intestinal tract—enterokinase. The conversion is brought about as soon as the trypsinogen comes into contact with the enterokinase, the merest trace of which suffices to activate a large amount of trypsinogen.

Trypsin acts on the protein just as pepsin does, by bringing about hydrolytic changes. It differs from the latter in acting best in an alkaline or neutral medium. Its effect is much more energetic than that of pepsin, so that the protein molecule is more completely decomposed.

The character and properties of the products formed in such digestion depend on the nature of the protein acted upon. As will be seen from the following table, proteins vary fairly widely in the proportion of amino acids which they contain.

Approximate Amino-Acid Percentage Composition of Several Proteins

	Gladin (wheat)	Gelatin	Caseinogen (milk)	Albumin (milk)	Fish muscle (protein)	Ox muscle (protein)
Glycine	0.0	25.5	0.45	0.37	0.00	2.06
Alanine	2.0	8.7	1.85	2.41	+	3.72
Valine	3.34	0.0	7.93	3.30	0.79	0.81
Leucine	6.62	7.1	9.7	14.03	10.33	11.65
Phenylalanine	2.35	1.4	3.88	1.25	3.04	3.15
Tyrosine	3.04	0.0	5.36	1.95	2.39	2.20
Serine	0.20	0.4	0.5	1.76	(?)	(?)
Cystine	2.40	0.16	0.25	4.1		
Proline	13.22	9.5	8.7	3.76	3.17	5.82
Hydroxyproline	?	14.1	0.23	0.0		
Aspartic acid	0.58	3.4	4.1	9.30	2.73	4.51
Glutamic acid	43.66	5.8	21.77	12.89	10.13	15.49
Hydroxyglutamic acid	2.40		10.5	10.00		
Tryptophan	1.10	0.0	1.6	2.40	Present	Present
Arginine	3.2	8.22	3.81	3.47	6.34	7.47
Lysine	0.63	5.02	8.38	9.87	7.45	7.59
Histidine	1.49	2.94	2.5	2.61	2.55	1.76
Ammonia	5.22	0.49	1.61	1.31	1.33	1.07

(b) *Diastase*. This ferment is found in the pancreatic juice apparently secreted in an active form, although some observers hold that it also is secreted in a zymogen form. It is practically identical in its action with the ptyalin of the saliva, converting starch into maltose. It deals with all the starchy food which has escaped conversion into the simple sugars by the ptyalin.

(c) *Lipase*. Most of this ferment, if not all, is apparently secreted in the form of a zymogen. There is evidence that the bile salts are the activating agent here, just as the enterokinase acts in the case of trypsin. Lipase can act in any medium acid, neutral or alkaline, and both on emulsified and non-emulsified fats. It converts the fats by a process of hydrolysis into fatty acids and glycerol. It has been found that not only can this enzyme break up fats into their components, but that it also has the power to act in the reverse direction, and in this way bring about the union of fatty acids and glycerol so as to form fats, a process which occurs in the intestinal epithelial cells after absorption.

2 *Intestinal Digestion*. By this is meant the other digestive processes which go on in the intestine under the action of the secretion of Lieberkühn's follicles—the *succus entericus*. This is a yellowish, often opalescent, strongly alkaline fluid. The alkalinity is due to the presence of sodium carbonate. Most of the ferments are found in very small amount in the intestinal juice. They seem to be present actually within the epithelial cells lining

the intestine, for extracts made from the intestinal mucous membrane are richer in ferments than the secretion.

The intestinal secretion contains no trace of a ferment acting on native protein, but a ferment—*erepsin*—is present in fair amount in the intestinal mucous membrane and in small amount in the secretion, which acts in an alkaline medium on proteoses, peptones, and on casein, converting them into amino acids. A lipase has also been detected which is very similar to pancreatic lipase; it, however, attacks only emulsified fats.

Several carbohydrate hydrolysing enzymes have been described in the small intestine. Invertase, the ferment which splits cane-sugar, is present in small amount in the secretion, more abundantly in the extract of mucous membrane. In all probability it deals with the saccharose after or in process of absorption. Maltase is also present in large amount, and here again in greater amount in the extract than in the secretion. The question of the presence of lactase has been much discussed, and it seems probable that suckling animals do possess this enzyme.

Bile.—This fluid, in all probability, has little direct action in ordinary digestion, although it contains substances which act indirectly. The bile salts act as solvents for fats and fatty acids, and as activators of pancreatic lipase. The salts also serve to keep cholesterol in solution. Bile is to be looked upon rather as an excretion, the result of the hepatic metabolism, than as a digestive juice. It has an orange-brown colour, but the colour varies according to the pigment present. It is more or less viscous (not so viscous as bile taken from the gall bladder) and has a specific gravity of about 1.010. It has a slightly alkaline reaction, a bitter taste and a characteristic smell. On analysis it is found to have over 2% of solids, of which more than half are organic. It contains in addition to a nucleo-albumin, derived mainly from the bile passages and gall bladder, bile acids, bile pigments, cholesterol, lecithine, etc. The most abundant solids are the salts of the bile acids, of which in man the most important is sodium glycocholate, sodium taurocholate being present in small amount. The bile acids are formed in the liver cells, and when the duct is ligatured they tend to accumulate in the blood.

The pigments amount to only about 0.2%. In human bile the chief pigment is bilirubin, whilst in herbivores biliverdin is more abundant. They are derived from the haemoglobin of the blood, but the pigments are iron-free. They may be regarded as purely excretory products arising from the breakdown of the haemoglobin of effete blood corpuscles.

Cholesterol is a monatomic alcohol, and is probably a waste product. Fats and lecithine are both derived from the liver cells. Of the inorganic constituents calcium phosphate is the most abundant.

The secretion of bile is practically continuous, but it seems to enter the duodenum intermittently. The taking of food increases the flow of bile. The entry of the acid chyme into the duodenum is the stimulus which brings about the ejection of the bile.

Faeces.—The bulk of the waste matter arising from the foods along with the secretions from the alimentary canal form the faeces. On a diet giving little residue the faeces are almost purely intestinal in origin. As a channel of excretion of nitrogenous metabolic waste products they are not very important, although they do play a certain part. The nature of the excreted nitrogenous substances has not been fully examined. It is, however, very difficult to come to any definite conclusion as to what is unabsorbed material and what excreted.

ABSORPTION

Stomach.—No absorption of food-stuffs takes place in the mouth. Absorption from the stomach occurs only to a small extent. Water passes rapidly through the stomach and is practically unabsorbed. Salts are apparently absorbed in a limited amount from their watery solution, the extent of absorption depending to some extent on the concentration of the solution. Sugar is also absorbed to a small extent from its solutions. Alcohol is readily absorbed from the stomach. A small amount of the products of protein digestion may be absorbed. There is no evidence that fats are absorbed under any conditions.

Intestine.—The greatest absorption of the foods takes place in the intestines, especially in the small intestine. It has been shown that practically all the protein digest products have disappeared before the lower end of the small intestine is reached. There are two channels for the removal of the material from the intestine: (1) the blood capillaries spread in the villi, and (2) the lacteals also present in the villi. The foods may reach the blood direct or through the various lymph channels into the thoracic duct and finally into the blood. The lacteals of the villi are channels for the absorption of the fatty parts of the food. The products of the digestion of the proteins and carbohydrates reach the body directly through the capillaries via the portal system. Whether the nervous system plays any part in absorption is not yet determined.

Carbohydrates. These reach the body, as already mentioned, by way of the blood, and in the form of monosaccharides or simple sugars. It has been shown that if lactose be put into a lactase-free intestine, no absorption takes place, the lactose gradually disappearing under bacterial action, whereas when the ferment lactase is present, glucose and galactose, the products of its splitting, are absorbed as readily as cane-sugar and maltose. The body deals with its carbohydrate supply in the form of monosaccharides as if solutions of various sugars, mono- and disaccharides be injected, it is found that the simple sugars are retained, whereas the double sugars are excreted in the urine. The only disaccharide which can be dealt with in the body is maltose, as there is a maltase present in the blood which splits it. Carbohydrates which are not absorbed from the intestine are disposed of by bacterial action.

Fats. Fats are absorbed from the intestine in the form of fatty acids and glycerol, *i.e.*, in the form in which they exist after the action of the lipase. That a resynthesis takes place in the epithelium is shown by the fact that as fat absorption goes on fat droplets are seen to grow in the protoplasm away from the free margin of the cells. As already mentioned, the fat is removed by the lacteals from the cells to the thoracic duct, and then to the general circulation. A small amount of the fat may pass into the body via the blood, but this is practically all retained by the liver. The amount of fat absorbed depends largely on the nature of the fat, especially with reference to its melting-point, fats of low melting-point being most readily taken up.

Protein. It is unquestionable in the light of modern work that the great bulk of the digested protein is absorbed from the intestine via the portal blood stream in the form of amino acids. The work of Abel with his *vivi*-diffusion apparatus demonstrated very clearly that amino acids circulated in the blood and the work of Folin and van Slyke demonstrated that the amino acids were taken up by the various tissues.

In the large intestine, little absorption of nutrient matter takes place under normal conditions, mainly of course because most of the absorbable material is removed whilst the food is in the small intestine. The principal substance absorbed here is water; and thus the excreta become firm and formed.

METABOLISM

Within the living protoplasmic mass of the tissue-cells activity is ceaseless. The whole series of changes has been given the name of metabolism and within this title are recognized the two phases of building up, *anabolism*, and of breaking down, *catabolism*. There is a constant interplay between these two phases, sometimes rapid, sometimes slow, with a straining towards an equilibrium which is never reached whilst life goes on. When this metabolism is analysed further it is customary to divide it into two parts, the metabolism of energy and the metabolism of matter or material. But it must be made clear that within the living cell metabolism is one and indivisible. Further, although for descriptive purposes it is necessary to discuss the metabolism of the different proximate principles, *e.g.*, protein, carbohydrate, etc., individually the fact must be appreciated that the living protoplasmic mass which forms the content of the cell is not a mere conglomerate of protein, carbohydrate, fat, salts and water, where each constituent may be envisaged as a separate entity. Protoplasm, on the contrary, is a complex colloid—an intimate compound of its various

constituents. No constituent can be metabolized without influencing the metabolism of the others.

Protein.—After absorption the amino acids are taken up by the cells of the various tissues and would seem for the most part to undergo sooner or later a disintegrative change, deamination, in which the amino group (NH_2), is broken off. It is commonly believed that the freed amino group is converted into ammonia (NH_3), which of course does not remain in the free state but becomes neutralized mainly by carbon dioxide to form ammonium carbonate. This ammonium carbonate in its turn is conveyed eventually to the liver, where it is finally transformed into urea and eventually excreted in the urine as a waste product. The nitrogen-free remainder is utilized for energy purposes either directly or indirectly. The work of Lusk and others has shown that under certain circumstances about 58% of the protein molecule can be converted into sugar. Such would seem to be the history of the fate of the bulk of the protein ingested. Of course a certain amount of the ingested material is not broken down in the way above described but is utilized intact by the organism as building material for the repair of tissue waste and for the formation of new tissue as in growth. Despite the variation in composition of the ingested proteins of a mixed diet the fact that all in the course of digestion are reduced to their simple amino-acid components serves a useful purpose in that it permits the various tissues, which have, of course, varying needs, to exercise a selective action over what they will retain and what reject. It is the composition of the tissues which determines the type of retention.

Evidence of the importance of the chemical composition of the protein fed has been had from another aspect which has shown definitely that the organism must receive certain, probably the majority, of its amino acids in the preformed state. Feeding experiments on young growing animals have been carried out where the protein fed was abnormal in that certain amino acids were completely absent. One of the proteins used was zein (from maize), which lacks the amino acids tryptophan and lysine. When young animals were fed on a well selected diet with zein as the sole protein they rapidly went downhill and died. When to the diet as before the appropriate amount of tryptophan was added to make good the deficiency in this amino acid, the animals remained alive but did not grow; when as a further addition lysine was added the animals not merely lived but grew.

Carbohydrate.—Carbohydrate may be regarded as the food-stuff which most readily gives up its energy in the organism. The tendency of modern work is to accept carbohydrate as the fuel. After absorption into the blood stream any excess above immediate requirements would seem to be deposited in the liver and muscles in the form of animal starch or glycogen as a readily available form of reserve. If there is a persistent over-ingestion the excess carbohydrate would seem to be converted into fat and thus there is built up a more permanent reserve of energy. Finally if the organism is suddenly flooded with sugar as the result of the ingestion of excessive amounts, much of the sugar is excreted as such in the urine—alimentary glycosuria. Normally the sugar is completely burnt in the organism to form carbon dioxide and water. The complete utilization of the sugar is intimately related to a special secretion of the pancreas to which the name of insulin has been given by its discoverers, Banting, Best, Macleod and Collip. When there is a disturbance of this insulin formation as in the disease known as diabetes, sugar is excreted as such in the urine, the body having lost the power to utilize it. Just how insulin acts is unknown. There is very good reason also, due primarily to the interesting work of Harden and Young on fermentation, to believe, certainly as regards muscle, that before the carbohydrate can be broken down it first enters into combination with phosphorus to form a hexose diphosphate.

Fat.—Fat is not apparently readily metabolized in the body, but it is not probably so stable as one might deduce from the apparent readiness with which it is deposited. It is undoubtedly, so to speak, invested capital, whereas carbohydrate may be looked upon as capital in current account or at most on deposit receipt. When combustion is carried out normally it is complete, the end

products being carbon dioxide and water. For this complete combustion it is essential that a certain amount of carbohydrate be present as is evidenced by the fact that when carbohydrate is withheld from the diet or when it is not available as in diabetes a condition known as acidosis ensues. In acidosis the combustion of fat ceases before combustion is complete, with the result that there is formed in the body and excreted in the urine β -hydroxybutyric acid, aceto-acetic acid and acetone. These substances can be caused to disappear from the urine if a supply of carbohydrate is made available. It would seem that there are two chemical actions involved in the breakdown of the long fatty acid chain, a special process of oxidation known as β -oxidation, associated with desaturation which renders the chain unstable. Although the evidence for the conversion of carbohydrate to fat is plain, there is still lacking indubitable evidence of the conversion of fat to carbohydrate, although many workers accept the idea.

Salts.—Although the mineral salts do not directly contribute to the supply of energy to the body and although generally speaking, they themselves undergo no metabolic change in the body they play a very important part in the various tissue activities. Unless the salts be present in proper amount and in proper proportion, metabolism is impossible. The principal mineral elements found in the body are sodium, potassium, calcium, magnesium, iron, phosphorus, sulphur, chlorine and iodine, with in addition traces of many other elements. Of course these various elements do not exist in the tissues in their free state but as compounds which, in the majority of instances, would seem to be inorganic. As all these substances are continually being lost from the body in the various excretions, it is essential that a sufficient supply be always available in the food. These mineral constituents play the main rôle in the maintenance of the faintly alkaline reaction of the various tissue fluids. As the result of the different metabolic processes which take place in the tissues there is a constant production of acid, chiefly from sulphur and phosphorus, which requires to be neutralized by basic elements like sodium and potassium and probably also calcium and magnesium. The kidney for the most part regulates in a very selective fashion the output of these various inorganic constituents. It must not be imagined, however, that the body can completely protect itself from excessive salt loss, a loss so great that it may give rise to symptoms of a serious character. Thus it has been shown that men who are, in the course of their work, exposed to high environmental temperatures with consequently much sweating, are very liable to a form of cramp. Further it has been noted that the cramp is frequently exacerbated where the men drink freely of water to allay their thirst. Recently it has been found that the condition is due to an excessive loss of sodium chloride from the body carried away in the sweat and that the condition may be cured or prevented by giving the men saline fluid to drink.

Although five-sixths of the total mineral matter of the body is found in bone and in spite of the fact that bone has all the appearance of being firm and resistant the evidence available goes to show that the bony structures must be regarded as active store-houses of mineral matter. When the need arises the body as a whole can draw upon the bones for constituents like lime and phosphates. Under certain conditions the bones indeed may give up so much of their mineral matter that they become soft and can no longer function as an effective frame work.

The other one-sixth of the mineral constituents found in the body are not distributed uniformly throughout the remainder of the tissues. As regards this varying distribution of salts in the tissues and the blood Macallum, in his study of palaeochemistry, produced some most interesting evidence in favour of his view that the present composition of the blood plasma, in so far as its inorganic constituents are concerned, is probably identical with that of the sea water just before the Cambrian period and that the salt concentration in protoplasm represents conceivably the salt concentration of the primaevial ocean in which life first appeared. At any rate the curious ratio of potassium and calcium to sodium, which is characteristic of protoplasm, is reflected in the salt relationship in water drawn from pre-Cambrian formations.

The mineral constituents play an important part without doubt

in digestion in that acid must be secreted for gastric digestion and alkali for intestinal digestion.

Water.—In so far as water forms about 60% of the body-weight of man it is very obvious that the part it plays in metabolism must be an important one. It is indeed true that the whole series of chemical actions which are so intimately related to the life of the living organism, be it animal or vegetable, are ultimately referable to changes which take place in solution. It has been conclusively shown that the younger the animal the richer it is in water. It has also been found that the fatter the animal the smaller the percentage amount of water present.

So far as is known water undergoes no change in the body, but nevertheless all the water present in the organism does not come from some source external to the body but is in part formed in the tissues during the metabolism of the various foodstuffs and of the tissues themselves. According to one calculation this internal source of supply accounts for about 16% of the water excreted. It has been also maintained that this intracellularly formed water is of greater value to the living structure than the imbibed water as it presumably does not bring about drastic osmotic changes. It is impossible, however, with the information now available to decide whether the metabolic water in the cell differs in any way from the water received from external sources.

It is of interest to note that animals which live in arid regions, in contradistinction to those which live where water is abundant, excrete as their main nitrogenous waste product uric acid which is voided with the minimum waste of water instead of urea, which has to be excreted in solution.

Methods of Investigation.—Brief reference may here be made to the methods employed in investigating metabolism. No matter the line of attack selected, the investigator is handicapped by the fact that he can only deal with the end products of metabolic activity.

If the extent and degree of metabolic activity of a subject have to be determined we may do so by direct calorimetry. The subject is enclosed in a special chamber or calorimeter so devised that all the heat given off by the subject can be directly collected and measured (fig. 1). These calorimeters, which we owe mainly to the ingenuity and skill of Atwater, Rosa and Benedict, are very delicate and costly pieces of apparatus. In order that there be no escape of the body heat to the environment, the double copper walls of the chamber are fitted up with elaborate electrical equipment which permits of so delicate a balance that heat can neither pass out nor into the chamber. In order to measure the heat given off by the subject, a current of cold water is circulated within the box in continuous piping. If the temperature of the incoming and outgoing water is carefully measured and if the

FIG. 1.—SCHEMA PRINCIPLES OF ATWATER-ROSA-BENEDICT RESPIRATION CALORIMETER

quantity of water passing through be also known the heat lost by radiation and conduction by the subject in a given time can be determined. As part of the heat lost, amounting to about one-fourth of the whole, is eliminated by the subject in the form of water vapour this must be and is also determined by absorbing the water lost in sulphuric acid and subsequent weighing of the acid container. This method of direct calorimetry is very accurate and reliable, but the method is difficult and the apparatus is very liable to get out of order. In addition to this direct measurement of the heat output, the metabolic activity of the subject

can be calculated from a determination of the amount of carbon dioxide given off and the amount of oxygen utilized by the subject in a given period. This method of Indirect Calorimetry can be carried out simultaneously with the direct method and serve as a check upon it. The calorimeter chamber in which the subject is enclosed is gas-tight and the air is circulated through a gas-tight absorbing system (fig. 1) by means of a rotary blower. The

FROM CATNACHT, PATON AND PEMBERT, "PRACTICAL PHYSIOLOGY" (EDWARD ARNOLD & CO.)
FIG. 2.—INDIRECT CALORIMETRY: DOUGLAS BAG

carbon dioxide given off is absorbed by means of soda lime, the amount absorbed being determined by weighing the soda lime container at the beginning and the end of the experiment. The carbon dioxide free air is returned to the chamber after the deficiency in oxygen, which is approximately determined by reduction in volume, has been made good from a cylinder of pure oxygen. The amount of oxygen used during the experiment is determined either by measuring by a meter the amount of oxygen passed in or by weighing the cylinder before and after the experiment. The heat lost by the subject can be determined from the amount of oxygen used. The caloric value of a litre of oxygen used in the tissue combustion has been determined. This value varies with the carbon dioxide-oxygen ratio, called also the respiratory quotient (R.Q.), from 4.795 calories with an R.Q. of .713 which is held to represent the combustion of fat alone to 5.058 calories with an R.Q. of 1.00, which is accepted as representing the combustion of pure carbohydrate by the tissues. The two methods of direct and indirect calorimetry have been found to give almost identical results.

It is obvious that the use of the chamber would act as a great handicap if the determination of energy expenditure were confined to it. To enable measurement of energy expenditure of subjects engaged in actual work a portable apparatus was first devised by Zuntz and later much simplified by Douglas (fig. 2). In this last form the subject wearing either a mask or special mouth-piece, with nose clip, fitted with two one-way valves breathes into a gas-tight bag carried on his back. The air collected in the bag at the end of the experiment is measured by passage through a meter, a sample of the expired air is analyzed in the Haldane gas analysis apparatus and the amount of carbon dioxide and oxygen present is determined. As the composition of the atmospheric air is known it is readily calculated how much carbon dioxide the subject excreted and how much oxygen is utilized in a given time and the caloric values can be determined as above. In order to relate the carbon dioxide output and oxygen utilization to the non-protein poeity of the food the protein metabolized during the period of the experiment is determined from the nitrogen output in the urine. For every gram of urinary nitrogen derived from protein 8.45g. of oxygen are required and 9.35g. of carbon dioxide are given off. Hence to determine the non-protein utilization the appropriate amounts of carbon dioxide and oxygen are deducted from the total amounts. As the amount of nitrogen excreted during the period of examination is minute, in practice it is usually ignored.

When the alterations of the gaseous metabolism are considered they are commonly referred to variations from the so-called Basal or Standard Metabolism. The basal metabolism may be defined as that of a subject lying comfortably at rest in a warm bed and in the post-absorptive condition, i.e., about 12 to 15 hours after the last meal. With the subject in such a condition the metabolism reaches its lowest level. As it has been estimated that functional activities of the various organs may account for about 25% of the resting metabolism (thus the activity of the heart for about 3.6%, respiratory movements for about 10% and the kidney for about 5%) Krogh maintains that it is better to call this resting metabolism standard rather than basal. It, of course, could only be truly basal if all functional activities were in abeyance at the time of the determination.

It is obvious, in view of the fact that humanity is of varying sex and size, that if a universally applicable standard is to be obtained there must be some fundamental unit on which to base assessments. It has been shown that body-weight is not satisfactory. The modern unit selected is the surface-area of the body. A very useful formula for the determination of this area based on height \times weight \times a constant has been worked out by E. F. and D. Du Bois. As the result of their work it is common practice now to take as the fundamental unit the calorie output per square metre surface area.

This basal metabolism is shown to be high in childhood and that as adolescence is reached it falls to a level which is more or less uniformly maintained until about the age of fifty. Thereafter the decline is steady although small. The basal metabolism is also influenced by the sex of the subject, the nature of the food consumed, and environmental conditions like temperature, climate, etc. The most potent factor is, however, muscular work.

FACTORS WHICH INFLUENCE NORMAL METABOLISM

Fasting.—During fasting the body draws upon its own reserve of stored material for its requirements in the production of energy, and the rate of breakdown varies with the energy requirements. An individual kept warm in bed, therefore, stands fasting longer than one who is compelled to take exercise in a cold place. The breakdown of tissue during the early days of a fast is much greater than later, for as the fast progresses the body becomes more economical in its utilization of tissue. During a fast the tissues do not waste at an equal rate; those which are not essential are utilized at a much greater rate than those which are essential to the maintenance of the organism. For instance, it has been shown that during a fast the skeletal muscles may lose over 40% of their weight, whereas an essential organ like the heart loses only some 3%.

The essential tissues obtain their nourishment from the less essential by ferment action, a process which has been termed auto-digestion or autolysis. The autolytic products of tissue digestion are practically identical with those which arise during the ordinary gastro-intestinal digestion.

Muscular Work.—The muscular tissue plays the most important part in general metabolism. Not only is muscle the most abundant tissue present, but it is constantly active and is the great energy-liberating machine of the body. Formerly it was believed on the authority of Liebig that muscular work was done at the expense of the protein material, but it has been conclusively shown that the real source of energy in moderate work is the non-protein material, carbohydrates and fats; of these the former plays the greater part in a man on ordinary diet. That there is some influence on protein is shown by the fact that there is a definite but small increase in the output of nitrogen in the urine as the result of muscular work, but it is in no sense proportionate to the work done; whereas the output of carbon dioxide produced by the combustion of the carbohydrates and of the fats is increased proportionately to the work done.

Internal Secretions.—Evidence is accumulating to show that the activities of the various tissues of the body are presided over and controlled not merely by the action of the nervous system but also by certain chemical substances elaborated in special glands known as endocrine glands or glands of internal secretion. The

active secretions of these glands are poured out into the blood stream. We have direct evidence that some of these secretions like thyroxin from the thyroid gland and insulin from the pancreas exercise a very active influence on metabolism. As regards the other secretions we know more about their action on various tissues than of their direct influence on metabolism.

EXCRETION

While we know comparatively little of the intermediate stages in the breakdown of the food constituents, and more particularly of the protein moiety, our knowledge of the final products of the metabolic changes excreted is fairly full. The urine is the main channel of excretion for the nitrogenous waste products. Water is excreted by the lungs, the kidneys and the skin.

The urine is a yellowish fluid which varies greatly in its depth of colour, from pale amber to a deep brown. It has a specific gravity of about 1020, varying with the percentage of solids in solution, and it usually has an acid reaction. Among the principal organic substances present are urea, ammonia, purins (uric acid and the so-called purin bases, xanthin, etc.), creatinine, conjugated sulphates, various aromatic bodies and many other substances in small amount, together with the water and inorganic salts.

The following table from Folin gives a good idea of the average composition of the urine as regards the nitrogen-containing constituents, and its variation according to the nature of the diet when this is free of creatin, creatinine and the precursors of the purins:—

	Nitrogen-rich diet	Nitrogen-poor diet
Total nitrogen	14.8-18.2g. per day	4.8-8.0g. per day
Ur-a nitrogen	86.3-80.4% of total	62.0-80.4% of total
Ammonia nitrogen	3.3-5.1% " "	4.2-11.7% " "
Creatinine nitrogen	3.2-4.5% " "	5.5-11.1% " "
Uric acid nitrogen	0.5-1.0% " "	1.2-2.4% " "
Undetermined nitrogen	2.7-5.3% " "	4.8-14.6% " "

Urea, which forms the chief nitrogenous constituent, amounting on an ordinary diet to about 30g. per diem, is for the most part formed in the liver, from ammonia obtained either directly from the blood after absorption from the intestine, or resulting from the deamination of the amino acids. There is at present a controversy as to the true chemical nature of this substance.

Ammonia is present in the form of ammonium salts, and forms about 4% of the total urinary nitrogen. It may exceed this amount under certain conditions, for the most part pathological. The ammonia is utilized by the body to neutralize acids which arise during the various metabolic processes.

Purins (uric acid, xanthin, hypoxanthin, etc.) are all members of a series which have as their common nucleus a body which E. Fischer called purin. The most important member of this series is uric acid. It forms about 2% of the total urinary nitrogen. Recent work has shown that it has two quite definite sources of origin: (1) from ingested food containing the precursors, and (2) from the tissue metabolism. The first is known as the exogenous source, and the second as the endogenous. This acid is chemically known as trioxypurin, and may be regarded as the union of two urea molecules with a three-carbon chain fatty acid. All the uric acid formed in the body is not excreted as such, part being, as already mentioned, converted into urea. The amount which is converted into urea varies with the species of animal. The other chief purin bodies present in urine are xanthin and hypoxanthin, purins less oxidized than uric acid; the first is a dioxypurin, and the second is a monoxypurin. The main source of total purin supply would seem to be muscle metabolism. The mother substances from which all are derived in the body are the nucleo proteins. These complex bodies are apparently first broken down by enzyme action to aminopurins. These in their turn have their amino groups split off, and then, according to the degree of oxidation, the different purin bodies are formed.

Creatinine. The physiological significance of this substance is

as yet unknown. The daily excretion varies little with the character of the diet, provided, of course, that the diet be creatinine-free. It would seem to be derived from the creatine of muscle, a substance which is very readily changed into creatinine outside the body. Whatever its source, after urea and ammonia it is one of the important nitrogenous substances excreted.

The **sulphur** excreted in the urine comes chiefly from the sulphur of the protein molecule. It is excreted in various forms: (1) as the ordinary preformed sulphates, i.e., sulphur in the form of sulphuric acid combined with the ordinary bases; (2) as ethereal sulphates, i.e., in combination with various aromatic substances like phenol, indol, etc.; (3) in the form of so-called neutral sulphur in such substances as cystin, which are intermediate products in the complete oxidation of sulphur.

Phosphorus appears linked to the alkalis and alkaline earths as phosphoric acid. A very small part of the phosphoric acid may be eliminated in organic combination such as the glycerophosphates, etc.

Sodium (mostly as sodium chloride), potassium, calcium and magnesium are the common bases present in the urine.

The lungs are the important channel of excretion for the waste product of carbon metabolism, carbon dioxide or CO₂ (see RESPIRATORY SYSTEM); and also a very important channel for the excretion of water. As regards the skin, the sweat carries off a large amount of the water. It has been estimated that about 900c.c. is excreted per diem under normal resting conditions, rising to 7,000c.c. and over when hard work is done. Sweat contains salts, chiefly sodium chloride, and organic waste products. Of the organic solids excreted from this source urea forms the most important under normal conditions. Under pathological conditions, especially when there is interference with free renal action, the amount of nitrogenous waste excreted may become important.

NUTTING, MARY ADELAIDE (1858—), American nurse educator, was born at Waterloo, Quebec, Canada, on Nov. 1, 1858. Educated in private schools, she became a member of the first class in the Johns Hopkins hospital school of nursing, Baltimore, of which school she was principal from 1894 to 1907, when she was given the chair of institutional administration at Teachers' college, Columbia university, New York. There in 1910 the first university department for the education of nurses was created and she was assigned to the chair of nursing and health. During the World War she was appointed by President Wilson chairman of the committee on nursing under the National Defence Council. In 1920 the "Adelaide Nutting Historical Collection," showing the progress in America and other countries of the profession she had helped to develop, was established in her honour at Teachers' college. She retired in 1925. With Lavinia Dock she wrote *A History of Nursing* and she was also the author of *A Sound Economic Basis for Schools of Nursing*.

NUX VOMICA, a poisonous drug, consisting of the seed of *Strychnos Nux-Vomica*, a tree (Fam. *Loganiaceae*) indigenous to most parts of India, and found also in Burma, Siam, Cochin China and northern Australia. The tree is of moderate size, with a short, thick, often crooked stem and ovate entire leaves, marked with three to five veins radiating from the base of the leaf. The flowers are small, greenish-white, tubular and arranged in terminal corymbs. The fruit is the size of a small orange, and has a thin hard shell, enclosing a bitter, gelatinous white pulp, in which from one to five seeds are vertically embedded. The seed is disc-shaped, about 1in. in diameter, and ½in. thick, slightly depressed towards the centre, and in some varieties furnished with an acute keel-like ridge at the margin. Externally, it is greyish-green and satiny from a coating of appressed silky hairs. Internally it consists chiefly of horny albumen, which is easily divided along its outer edge into halves by a fissure, in which lies the embryo. The latter is about ⅓in. long, and has a pair of heart-shaped membranous cotyledons.

The chief constituents of the seeds are the alkaloids strychnine (*q.v.*) and brucine, the former averaging about 0.4%, and the latter about half this amount. The seeds also contain an acid, strychnic or igasuric acid; a glucoside, loganin; sugar and fat. The pharmacology of *nux vomica* is practically that of strychnine.

NYACK, a village of Rockland county, New York, U.S.A., on the west bank of the Hudson river (which here expands into Tappan Zee, 3 m. wide) 25 m. above New York city. It is served by the Erie railroad and a ferry to Tarrytown, nearly opposite. Pop. (1920) 4,444 (81% native white). With the adjacent villages of Upper Nyack and South Nyack, the population was estimated locally at 10,000 in 1928. The industries include shipyards, machine shops and several factories. Permanent settlement here dates from about 1700. Nyack was incorporated in 1833 and was named after a tribe of Algonkin Indians.

NYANZA, the Bantu name for any water area of considerable size; especially applied to the great lakes of east Central Africa. The word is variously spelt, e.g., Nyanja, and Nyasa.

NYASA, the third in size of the great lakes of Central Africa. It occurs south of the confluence of the two great rift valleys and extends from 9° 29' S. to 14° 25' S. The lake measures along its major axis, which is slightly inclined to the west of north, exactly 350 m., while the breadth varies very little, the maximum being 45 m. about the middle. The total area may be estimated at 11,000 sq.m. The lake lies at an altitude of about 1,650 ft. above the sea. The sides of the valley in which Nyasa lies, which are somewhat irregular towards its southern end, take a decided character of parallel fault scarps in the northern third, and are continued as such beyond the northern extremity. The depth seems to vary between 200 and 400 fathoms, in accordance with the steepness of the shores. The lake receives its water-supply chiefly from the streams which descend from the mountains to the north, all the rest becoming very small in the dry season. Like other lakes of Central Africa it is subject to fluctuations of level, apparently caused by alternations of dry and wet series of years.

At the north-western end is a plain of great fertility, traversed by the Kivira, Songwe and other streams. On the delta of the Rukuru, is the British station of Karonga, the northern port of call for the lake steamers. Southwards the plain narrows, and the sandstone scarp of Mt. Waller rises sheer above Florence bay, the high western plateaux continuing to fall steeply to the water. At Cape Chirombo (11° 40' S.) the coast bends to the west, and soon the plateau escarpments recede, and are separated from the lake along its southern half by an undulating plain of varying width, with Bandawe and Kota Kota ports on the coasts. A little north of the latter the Bua river, coming from a remote source on the upper plateau, enters by a projecting delta. At Domira bay the coast turns east, contracting the lake to a narrow neck, with Fort Rifu (west), and Fort Maguire, near Makanjira point (east). Beyond this the lake runs southwards into two bays separated by a granitoid peninsula, off which lie several small rocky islands. From the extremity of the eastern bay the Shiré makes its exit to the Zambezi. On the eastern side the escarpments and the boundary fault keep close to the lake, leaving few plains along its shores. In the north-east, the coast is formed by the unbroken wall of the Livingstone range (*q.v.*). On this coast is the station of Lumbira (Tanganyika Territory). The valley of the Ruhuhu, the only important stream which enters the lake from the east, breaks through the Livingstone range. The formation is here Karroo sandstone, corresponding to that of Mt. Waller on the opposite shore. Just north of the Ruhuhu is Manda, on an excellent harbour. To the south the wall of mountains recedes somewhat, and the remainder of the eastern shore shows a variation between rocky cliffs, marshy plains and low hills, to be followed farther south by a wide semicircular bay, generally rock-bound, and ending in Malo point, off which are the largest islands the lake possesses, Likoma and Chisamulu. In the southern half the coast is highest where the Mapangi hills rise to 3,000 ft.

Nyasa, reached in 1859 both by David Livingstone (from the south) and by the German, Albrecht Roscher (from the east), was explored by the former to about 11°, and to its northern end by E. D. Young in 1876. From this date onwards it has been the

scene of much civilizing work on the part of British missionaries, traders and government officials, and of Germans also. Its shores are divided between Great Britain (with Tanganyika Territory and Nyasaland Protectorate) and Portugal (with Portuguese East Africa). British steamers, including gunboats, have been launched on Nyasa, which forms an important link in the water-route from the Zambezi mouth to the heart of the continent. The first detailed survey of its shores was executed by Dr. James Stewart (1876-1877), but this has been superseded by later work.

BIBLIOGRAPHY.—A. R. Andrew and T. E. G. Bailey, "The Geology of Nyasaland," with note on fossil plants, fish remains, etc., by E. A. N. Arber and others and bibliography in vol. 66 of *Quart. Jnl. Geol. Society* (May 1910); Gen. J. C. Smuts, "East Africa," *Geogr. Journal* (1918); also Blue books and Colonial Office reports.

NYASALAND PROTECTORATE. Nyasaland covers rather more than 40,000 sq.m., of which 37,800 are land. The country is situated between 9° 45' and 17° 15' S., and between 33° and 36° E. Its length from north to south is about 520 m., while its width varies from 50 to 100 miles. It is bounded on the west by northern Rhodesia and Portuguese East Africa, on the north-east by Tanganyika Territory, and on the east and south by Portuguese East Africa. The northern half of its eastern boundary is formed by Lake Nyasa.

Physical Features.—Nyasaland consists of elevated plateaux, sometimes separated by low-lying ground. The most important of these are the Nkonde mountains in the north-west, 6,000 to 7,000 ft. high, the Nyika plateau, rising to over 8,000 ft., and the Angoniland plateau, whose highest points range between 5,000 and 6,000 ft., both of these plateaux being on the western side of the lake: the Mlanje massif, in the extreme south-east, mostly over 6,000 ft., with several peaks rising above the general level, one attaining 9,843 ft., and the Shiré highlands between Lake Shirwa and the Shiré river, reaching, in their highest point, an elevation of 7,000 feet.

Lake Nyasa (*q.v.*), situated 1,645 ft. above sea-level, receives a number of comparatively small rivers from the neighbouring highlands, and is drained southward by the Shiré river, which flows into the Zambezi. The lake has few good harbours, and is swept from time to time by violent northerly and southerly winds. Other large lakes are Lake Shirwa and Lake Chiuta, a sheet of water situated north of Lake Shirwa, and being 30 m. long and from 2 to 8 m. broad. The water of Lake Chiuta, like that of Lake Nyasa, is fresh.

Climate.—In the low-lying regions about the Shiré river and the lakes, the climate is hot and trying; the temperature may rise to 120° in the shade, and the annual rainfall is less than 35 inches. The climate of the plateaux is naturally somewhat cooler and more healthy; frost may occur at night during the cool season, though even then the day temperatures may be considerable. The rainy season lasts from the end of November to the end of March, but the rains vary considerably in quantity and duration. Records are insufficient to give reliable averages, but some of the higher stations may receive from 40 to 60 in. per annum. Much of the rain may fall in short, heavy showers. Europeans living in Nyasaland need to spend a period in a temperate climate every few years to recuperate their vitality. Malaria and blackwater fever are fairly common.

Vegetation.—Large tracts of the country are still covered with forest, especially away from the centres of European or native settlement. The forests are of little economic value, apart from their effect in checking rapid run-off and soil erosion. Most of the trees are small, the diameter of their trunks at about 4 ft. from the ground being usually from 4 to 12 inches. Timber trees of greater size and value are to be found in damp ravines on the mountain sides and along the banks of the rivers. The most important of these are the patches of Mlanje cypress (*Widdingtonia Whytei*), which yields a soft, durable wood, immune from the attacks of termites. These trees grow on the higher slopes of Mlanje mountain, and are not found elsewhere in Nyasaland. Two species of *Brachystegia*—*Mombo* and *Nchenka*—provide the natives with material for bark cloth and ropes. Tree planting is encouraged, and seeds are easily procurable of the Mlanje cypress, and of several kinds of eucalyptus, which is the most important

of the exotic trees.

Population.—In 1925 the population consisted of 1,462 Europeans, most of whom live in the Shiré highlands, 669 Asiatics, and 1,210,344 natives. (See separate articles on the tribes YAOS, ANCONI, etc.). In 1901 the native population numbered only 736,724, the subsequent increase being due, to a considerable extent, to the immigration of Anguru from Portuguese territory.

Communications.—Passengers and cargo, landing at Chinde, may proceed up the Zambezi to Chindio, and thence by rail to Port Herald and Blantyre (*q.v.*). In the wet season boats may ascend the Shiré as far as Port Herald. The economic progress of the country waits upon the development of transport. In 1922 a line was opened from the Zambezi opposite to Chindio, to Beira, there linking up Nyasaland with a modern port. The lack of a bridge across the Zambezi is, however, a serious handicap. A railway from Luchenza, on the Shiré Highlands railway, to the southern end of Lake Nyasa, is also projected. It would do much to open up the northern districts. On the lake is a regular service of ships. The cheapest form of transport in the outlying districts is the ox-wagon, where that is possible. In the more settled areas motor transport is being increasingly used, and most of the white settlers have either a motor car or motor cycle.

Economic Development.—Most of the country is composed of igneous and metamorphic rocks. Comparatively small areas are covered by sedimentary rocks, but among the latter are equivalents of the South African Karroo system, in which some coal occurs. Other minerals occur, apparently sporadically, such as graphite, gold, etc. At present there are no minerals being exploited on a commercial scale. Agriculture and pastoralism are, and will probably continue to be, the chief occupations. Native labour is cheap, the usual wage being 6 s. or 7 s. per month, but the more ambitious natives emigrate to Rhodesia and South Africa, attracted by higher wages. Various crops have been popular in turns. Among these are coffee, cotton and tobacco, the latter being the most important at the present time. In 1921, 14,218 ac. were under tobacco, and nearly five million pounds were exported. The extent of cotton cultivation declined from 28,372 ac. in 1917–18 to 18,274 in 1920. The difficulty of transport makes cotton growing in the outlying districts unprofitable when prices are low. Gineries have, however, been erected, even in remote parts of the country, and efforts are being made to encourage cotton growing among the natives. Tea is grown in the high rainfall area on the south-east slopes of Mlanje mountain. Coffee planting has declined, because of the irregularity of the rainfall. Sisal hemp (*Cegroe rigida var sisilana*) and Mauritius hemp grow well in loose, sandy soil throughout Nyasaland, but the lower Shiré and the lake districts are probably the most suitable for them. Maize is cultivated on the hills by the natives. The native tribes keep cattle, non-woolled sheep, goats and pigs in various parts, but there are large areas from which cattle are excluded by the tsetse fly. Various tick-borne diseases, such as east coast fever, are also rather common.

The chief imports are provisions, building material, agricultural implements, vehicles, and textiles for native clothing.

Administration.—At the head of the administration is a governor, assisted by executive and legislative councils, nominated by the Crown. The headquarters are at Zomba, situated at the foot of the Zomba plateau. The township is lighted by electricity and has a hospital and two churches. Nyasaland is divided into three provinces, each in charge of a provincial commissioner, under whom are residents of districts, whose chief duties are, naturally, in connection with native affairs. A good deal of responsibility is given to native chiefs and headmen, who are used as the medium of communication between the residents and the tribesmen.

Education and Religion.—Though many of the native people are either heathens or Mohammedans, there are several thriving Christian missions in the country. Among these may be mentioned the Universities mission, with a large cathedral at Likoma, the Livingstonia mission of the United Free Church of Scotland, the Church of Scotland mission, with its headquarters at Blantyre, the Dutch Reformed Church of South Africa mission and the

White Fathers. Most of these missions do a large amount of educational and medical work among the natives. In 1924 there were 2,447 native schools in the country. The educational training is varied. Apart from the usual school training, leading on to training colleges for teachers, courses are given in theology, medicine, and the various crafts. At Limbe is a school, kept by Marist Fathers, for white children.

See Sir H. H. Johnston, *British Central Africa* (1897); *Handbook of Nyasaland* (1922). (R. U. S.)

HISTORY

The modern story of Nyasaland begins with the coming of David Livingstone, who in his Zambezi expedition penetrated up the Shiré affluent of that river and discovered Lake Nyasa. That was in 1859. Livingstone's subsequent journeys to the south end of Lake Tanganyika, to Lake Mweru and to Lake Bangweulu (where he died in 1873), opened up this part of South Central Africa, and centred in it British interests in a very particular manner. Livingstone's discovery of Lake Nyasa was soon followed by the entry of various missionary societies, and these missionaries, together with a few Scottish settlers, steadily opposed the attempts of the Portuguese to extend their sway from Mozambique or their settlements on the Zambezi to the newly opened up country. Out of the missionary societies grew a trading company, the African Lakes Trading Corporation. Blantyre was founded and in 1883 the first British consul was sent out. Soon afterwards the settlers came into conflict with a number of Arab slavers who had established themselves at the north end of Lake Nyasa. About 1885 a struggle began between Arab and Briton for the possession of the country, which was not ended until the year 1896. The African Lakes Corporation in its unofficial war enlisted volunteers, amongst whom were Captain (afterwards Lord) Lugard and Mr. (afterwards Sir) Alfred Sharpe. Both these men were wounded, and the operations they undertook were not crowned with complete success. At this time "the scramble for Africa" among European Powers was acute and in 1889 the British South Africa Company obtained a charter and sent emissaries to Central Africa. In the same year Mr. (afterwards Sir) H. H. Johnston was sent out to endeavour to effect an arrangement between the Arabs and the African Lakes Corporation, and also to ensure the protection from Portuguese aggression of the region where the British settlers had established rights of occupation, and of native chiefs who owed no allegiance to Portugal. The outcome of these efforts and the treaties made was the creation of the British protectorate and sphere of influence north of the Zambezi. The dispute with Portugal was settled by a convention signed in 1891, when Johnston returned to the country as imperial commissioner and consul-general. In the interval between 1889 and 1891 Alfred Sharpe and others, on behalf of Cecil Rhodes, had brought a large area west and north of Lake Nyasa into treaty with the British South Africa Company. A British protectorate over the regions adjoining the Shiré and Nyasa was formally proclaimed in 1892, the adjacent territories, now part of Northern Rhodesia, being administered for four years by Sir Harry Johnston on behalf of the Chartered Company. Between 1891 and 1895 a long struggle continued, between the British authorities on the one hand and the Arabs and Mohammedan Yaos on the other, over the suppression of the slave trade. By the beginning of 1896 the last Arab stronghold was taken and the Yaos were reduced to submission. Then followed, during 1896–98, wars with the Zulu (Angoni) tribes, who claimed to dominate and harass the native populations to the west of Lake Nyasa. The Angoni having been subdued, and the British South Africa Company having quelled the turbulent Awemba and Bashukulumbwe, a period of peaceful development followed.

The great majority of the inhabitants had from the first accepted and even welcomed British rule, and they made distinct progress. Besides the example of the white officials there was the influence of the missionaries, both strong and beneficent. Of the three chief societies represented, two were Presbyterian and one Anglican; of missionaries, Dr. Robert Laws, who worked over 50 years in the country, was pre-eminent for his civilizing and edu-

cational work and his statesmanlike qualities.

Sir Harry Johnston was succeeded as commissioner in 1897 by Sir Alfred Sharpe, whose intimate knowledge of the country was valuable in the work of development. The progress made was marked in 1904 by the transfer of the protectorate, up to that time under Foreign Office control, to the Colonial Office. In 1907 the title of the chief official was changed from commissioner to governor and in the same year executive and legislative councils were established. Called at first the Nyasaland Protectorate, the name had been changed in 1893 to "The British Central Africa Protectorate," but in 1907 the old name was revived. When in 1910, Sir Alfred Sharpe retired, the urgent problems awaiting solution were economic; chief concern being over Nyasaland's communications with the sea, the river route having proved unsatisfactory. When the World War began northern Nyasaland was invaded by Germans from East Africa. The governor, Mr. (later Sir) George Smith, was capable and energetic, and he received the full support of the people (black and white). The Germans were repelled, and later Nyasaland became a base for operations against them. There was, however, during the war, a disquieting incident. Among the natives were a number of professed Christians who claimed freedom from white control. One of these men, John Chelembwe, who had been educated in the United States, on his return built a church and preached the independence of Africans. With some 500 followers he rose in revolt in Jan. 1915. Three white settlers were murdered, one a Mr. Livingstone (a descendant of David Livingstone), and Chelembwe preached a sermon in his church with Mr. Livingstone's head placed on the pulpit. The revolt was speedily suppressed by a small force of British and natives, Chelembwe, who had taken to flight, being shot dead (Feb. 3), by native police. This rising was a symptom of Ethiopianism.

A number of men who came from South Africa or Great Britain during the war settled in Nyasaland as planters. But except in the Shiré highlands little of the country is suitable for Europeans. As was said by the governor, Sir Charles Bowring, in 1924, "The prosperity of the protectorate depends on the development of its tropical agricultural resources, partly by a limited number of European plantations, but principally by the natives themselves with European instructors."

To overcome transport difficulties, a railway, completed in 1915, was built from Port Herald, on the Shiré, to Chindi, on the north bank of the Zambezi, and in 1922 another railway, from Beira to the southern bank of the Zambezi, was opened.

The chief exports are now tobacco, cotton, tea and fibres. Imports, which in 1910-11 were valued at £111,000, had risen to £869,462 in 1928. Exports were valued at £97,000 in 1910-11 and at £706,756 in 1924. Revenue, which was £76,000 in 1909-10, was estimated at £380,000 in 1928, while expenditure rose in the years named from £108,000 to £381,948.

See *Nyasaland* (1920), a handbook, with bibl., issued by the British Foreign Office; S. S. Murray, *A Handbook of Nyasaland* (1922), the *Report of the East African Commission* (1925); and the annual report issued by the Colonial Office, London. (F. R. C.)

NYBORG, a seaport of Denmark on the island of Fünen, in the amt (county) of Svendborg. Pop. (1928), 9,836. The town was founded in the 12th century and a castle erected on Knudshoved (Canute's Head). From the 13th to the 15th century Nyborg was one of the most important places in Denmark. In 1658 it was held by the Swedes for about a year. The fortress, built by Christian IV. and Frederick III., was dismantled in 1869, and the ruins of the castle are used as a prison.

NYE, EDGAR WILSON (1850-1896), American humorist, was born at Shirley, Me., on Aug. 25, 1850. His parents removed to a farm on the St. Croix river in northern Wisconsin in 1852, and young Nye was educated in Wisconsin at the academy at River Falls, where he studied law. In 1876 he was admitted to the bar at Laramie, Wyo., where he served as justice of the peace, superintendent of schools, member of the city council and postmaster. Here he began to contribute humorous articles under the pseudonym of "Bill Nye" to newspapers, especially the *Cheyenne Sun* and the *Denver Tribune*. In 1881 he founded at

Laramie the *Boomerang*, and his reputation as a humorist was soon widespread. Later he became a successful lecturer, and in 1885, with James Whitcomb Riley, the poet, made an extended tour through the country, each reading from his own writings. Nye removed to New York city in 1886, and passed the later years of his life at Arden, a village in North Carolina, where he died on Feb. 22, 1896. His principal books are *Bill Nye and Boomerang* (1881); *Forty Liars and other Lies* (1882); *Nye and Riley's Railway Guide* (1886), with James Whitcomb Riley; and two comic histories, *Bill Nye's History of the United States* (1894) and *Bill Nye's History of England from the Druids to the Reign of Henry VIII.* (1896).

See *Bill Nye, His Own Life Story; continuity* by F. W. Nye (1926).

NYIKA. This Swahili word means "forest and thorn bush country" and is used by the Swahili to designate a set of Eastern Bantu tribes, who during the 16th century under pressure from the Galla migrated down the coast from the steppes on the left bank of the Tana river. It does not include the Taita, Pokomo, Segeju and Akamba, though these are ethnically connected with the tribes to whom it is applied. The nine tribes included in the term Nyika are the Giryama, now living about 3° south of the Equator, the Rabai, the Duruma and the Digo—all upper Nyika tribes and the most important of the group: the other five are the lower Nyika—the Kauwa, Chonyi, Dzihana, Kambe and the Rihe or Ribe.

Generally speaking they are tall, muscular, well set up and broad-headed. The Digo, however, though well built are slender and have refined oval faces. There are evident affinities with the Northern Hamites, and their general colour is dark brown, becoming paler the nearer Mt. Kilimanjaro is approached. Waist clothes are worn by the men, and women wear many pleated-kilts, but are nude from the waist up, though now the tendency is to dress like Swahili women.

The *kaya* or fortified village was fundamental to their clan organization, but now that war is no longer anticipated, and villages are built outside the fortification, it has lost some of its significance, though still used for the assemblies of elders. The *kaya* is always situated on a hill or in a dense forest and is strongly palisaded. The Pokomo build circular huts like the Galla, but this group generally is characterized by rectangular huts, with a ridge-pole and a thatched roof extending to the ground and thus dispensing with walls. The houses are either gable- or hip-ended.

The Nyika tribes are divided into exogamous clans, which observe certain prohibitions and avoidances and share a general veneration for the hyaena in which all the cognate tribes join except the Pokomo: but now at any rate there is no trace of totemism. The clans of the Digo and Duruma are matrilineal; the rest are patrilineal with the exception of the Rabai, who are in a transitional stage. The Rabai have two sets of clans, male and female, and every man inherits the clan of his father and of his mother, but for all practical purposes he is reckoned as a member of his father's clan; a woman, on the other hand, while she similarly inherits both clans, stresses the mother's. Every clan has its own clubhouse (*iwanda*) and there is also the *moro* or council house, which is the general inter-clan meeting place for men, and houses the friction drum used for convening the council.

The Digo, probably under Arab influence, have hereditary sultans, but otherwise there are no paramount chiefs. The government is in the hands of elders, who wear an ivory armlet as a badge of office. Every 13 years males have to be initiated at circumcision into an association analogous to *Massai* age-grades and after passing through the preliminary degrees they eventually reach the status of elders, among whom there is an inner circle called the *Hyaena*, which alone knows all the magical spells and consequently inspires great terror. From this circle are selected the "owners of the land," who carry on the government during the space of a *rika* or circumcision cycle.

The bow is the most usual weapon and the arrows are often poisoned. They also carry swords which are, however, as much implements as weapons. The Giryama have a parrying stick unique in the eastern area. Agriculture is carried on by women

who grow maize, millet, vegetables and sweet potatoes. They have sheep and goats but few cattle, and like most of the coastal tribes are careful not to take the cattle out till the heavy dew has dried from the grass, a precaution which does not seem to be necessary to the Bantu and Nilo-Hamitics living at higher altitudes.

The Nyika worship the typical Eastern Bantu deity *mulungu*, a vague abstraction of the sky combined with ancestor-worship with the main emphasis on the latter, the spirits of the dead (*koma*) surviving mortality and taking the world of the living under their charge. *Mulungu* is the dispenser and creator and from his union with the earth have sprung all things in the world including human beings, who are *mulungu's* hens and chickens. There are no professional rainmakers.

NYIREGYHAZA, the capital of the county of Szabolcs, in Hungary, is situated on the sandy loess Nyirseg plateau. It is an agricultural centre, specializing in the intensive cultivation of fruit and vines. There are also small manufactures, e.g., of soda, soap and agricultural machinery. Pop. (1920), 43,340.

NYKÖPING, a seaport of Sweden, chief town of the district (*län*) of Södermanland, 98 m. S.W. of Stockholm by a branch from the Stockholm-Malmö railway. Pop. (1928), 12,201.

Nyköping (i.e., New-Market, Latinized as *Nicopia*) begins to appear as a town early in the 13th century. Its castle was the seat of the kings of Södermanland, and after those of Stockholm and Kalmar was the strongest in Sweden. It was burned by Albert of Mecklenburg's party in 1389, by an accidental conflagration in 1665, and by the Russians in 1719. Nyköping lies at the head of the Byfjord, an inlet of the Baltic. The ruins of its once famous castle, the town hall (1662), and the district governor's residence, are notable buildings.

NYMPH, in zoology, is the name given to the immature stages through which all insects with incomplete metamorphosis

pass after leaving the egg. At its last moult the nymph gives rise to the perfect insect. (See INSECTS.)

NYMPHAEUM, a monument consecrated to the nymphs (*q.v.*), especially those of springs. These monuments were originally natural grottoes, which were traditionally considered the habitations of the nymphs. They were arranged to furnish a supply of water. Subsequently, artificial grottoes took the place of natural. The nymphaea of the Roman period were borrowed from the Hellenistic east (e.g., The Great Nymphaeum of Ephesus). The majority were rotundas, adorned with statues and paintings. They served the threefold purpose of sanctuaries, reservoirs and assembly-rooms. A special feature was their use for the celebration of marriages. Such nymphaea existed at Corinth, Antioch and Constantinople; the remains of some 20 have been found at Rome and of many in Asia Minor, Syria and Africa. The term nymphaeum was also applied to the fountain in the atrium of the Christian basilica. (See FOUNTAIN.)

NYMPHS, in Greek mythology, the generic name of a large number of female divinities of inferior rank. The word, the etymology of which is uncertain, seems to mean simply a marriageable woman; this is appropriate, as they are mostly associated with fertile, growing things (as trees), or with water. They are frequently associated with the superior divinities, as Artemis, Apollo, Dionysus, Pan and Hermes (*q.v.*).

The nymphs were distinguished according to the different spheres of nature with which they were connected. Sea nymphs were *Oceanids* or *Nereids*, daughters of Oceanus or Nereus. *Naiades* (from Gr. *ναειν*, flow, cf. *νᾶμα*, stream) presided over springs, rivers and lakes. *Oreades* (*ὄρος*, mountain) were nymphs of mountains and grottoes, one of the most famous of whom was Echo. *Napaeae* (*νάπη*, dell) and *Alseides* (*ἄλσος*, grove) were nymphs of glens and groves. *Dryades* (*q.v.*) or *Hama-dryades* were nymphs of forests and trees.

In Italy they tended to be identified with native divinities of springs and streams (Iuturna, Egeria, Carmentis, Fons), while the *Lymphae* (originally *Lumpae*), Italian water-goddesses, owing to the accidental similarity of name, were identified with the Greek Nymphae.

This letter, the fourth vowel of the modern alphabet, corresponds to the Semitic *ayin*, which represented not a vowel but a breathing. The Greeks, or possibly their Asianic predecessors, in adapting the Semitic alphabet to their own use used this letter (*omicron*) to express the vowel *o*, as was the case also with the letters *aleph*, *he*, *cheth* and *yodh*. Vowels were not expressed alphabetically in Semitic. The form of the letter on the Moabite stone was small, *o*, and this small form appears in early Greek inscriptions from Thera and Corinth. In Corinth and in the inscriptions from Abu-Simbel in Egypt there is a form *o*. A form with a dot in the centre occurs in Thera, *o*, and this is paralleled in the large Etruscan *o*. At Miletus a form *o* occurs. The Latin form, taken from the Chalcidic or Etruscan, was *o*. The minuscule form retains the shape of the majuscule letter.

The Greeks used the letter to represent the short close vowel *ō*. For the long vowel they used a sign *Ω* (*omega*) probably adapted

THE DEVELOPMENT OF THE LETTER "O" FROM THE EARLIEST TIMES TO THE PRESENT DAY

from *o* to one of the forms of which in use at Miletus it closely approximates. The western dialects used *Ω* to represent the long vowel, whether open or close. In the east it was used only for the open vowel, *ou* being used for the long close vowel as well as for the true diphthong. In the Cyclades however a reversal of this process frequently took place. *Ω* being used for the close sound whether long or short, *o* for the open. In Latin the letter stood for the same vowel without distinction of length, and the sound has passed almost unchanged into the Romance languages.

In modern English the vowel has undergone changes. The long *ō* has become a diphthong (*ou*) as in the words *bone*, *rose*. Short *ō* has become more open and lower, as in *rob*. Before the consonant *r* the sound is rounded and pronounced very far back in the mouth, e.g., *glory*, *north*. In the word *do* the single letter is used where a more usual orthography would require its doubling. Again in the word *son* one would expect the vowel *u*. In words such as *word*, *work*, *world* the sound has been affected by the preceding bilabial. The short sound is the descendant of Middle English short *ō* in which both the close and open short *ō*, which were distinguished in Old English, met. The long *ō*, now a diphthong, descends from Middle English long *ō*, an open sound, which was derived from Old English long *ā*. In Middle English this was a rounded back vowel akin to the modern vowel in the words *shore*, *north*. Old English close long *ō* became in Middle English *oo* (*ū*). (B. F. C. A.)

OAK, the name given to trees and shrubs of the botanical genus *Quercus* of the beech family (Fagaceae, *q.v.*), a large group which includes some of the most important timber trees. The oaks are widely distributed over the temperate parts of Europe, Asia, northern Africa and North America, and extend southward in mountains and highlands into the Tropics. On the mountains of Europe and North America they grow only at modern elevations and none approach the arctic circle. The tendency of many species to vary in a marked degree and the existence of numerous hybrid forms makes the determination of the exact number of species difficult, but it is estimated at from about 300 to upwards of 500.

The oaks are readily distinguished by their peculiar fruit, an acorn or nut, enclosed at the base in a woody cup. The female flower contains a single ovary, three-celled at first, but becoming one-celled and one-seeded by abortion. The male flowers are in small clusters on the usually slender and pendent stalk, forming an interrupted catkin. The alternate leaves are more or less deeply lobed or cut in many species, but in some of the deciduous and many of the evergreen kinds are nearly or quite entire on the margin.

The well-known *Q. Robur*, one of the most valued of the oaks, and the most celebrated in history and myth, may be taken as a type of oaks with sinuated leaves. Though known in England, where it is the only indigenous species, as the British oak, it is a native of most of the milder parts of Europe and of the Caucasus mountains in Asia. In Great Britain and in most of its Continental habitats two varieties exist, now usually regarded as distinct species: one, *Q. pedunculata*, has the acorns, generally two or more together, on long stalks, and the leaves nearly sessile; while in the other, *Q. sessiliflora*, the fruit is without or with a very short peduncle, and the leaves are furnished with well-developed petioles. The British oak is one of the large trees of the genus, though old specimens are often more remarkable for the great size of the trunk and main boughs than for very lofty growth. The spreading branches have a tendency to assume a tortuous form, causing a zigzag development; to this peculiarity the picturesque aspect of ancient oaks is largely due. When standing in dense woods the trees are rather straight and formal in early growth, and the gnarled character traditionally assigned to the oak applies chiefly to its advanced age. The fruit is shed the first autumn.

Vast oak forests still covered the greater part of England and central Europe in the earlier historic period. Many of the ancient oaks that remain in England may date from Saxon times; the growth of trees after the trunk has become hollow is extremely slow, and the age of such venerable giants is only a matter of vague surmise. The celebrated Newland oak in Gloucestershire, known for centuries as "the great oak," was 47½ ft. in girth at 5 ft. from the ground. The wood of the British oak, when grown in perfection, is one of the most valuable produced in temperate climates.

The heart-wood varies in colour from dark brown to pale yellowish-brown; hard, close-grained, and little liable to split accidentally. The oak of Britain was formerly in great demand for the construction of merchant shipping. The finely-grained heart-wood is sought by the cabinetmaker for the manufacture of furniture, as are also the gnarled and knotted portions of slowly-grown trees, which are sawn into veneers. Oak was formerly largely used by wood-carvers and was thus applied at a very early date; the shrine of Edward the Confessor, still existing in the abbey at Westminster, sound after the lapse of 800 years, is of dark-coloured oak-wood.

The cultivation of this oak in Europe forms one of the most important branches of forestry. Its growth is slow, though it varies greatly in different trees; when grown for large timber oak can rarely be profitably felled till the first century of its growth is completed. The British oak is often grown as an ornamental tree in the eastern United States, where, however, it is usually short-lived. In the southern parts of Australia and in New Zealand it seems to flourish as well as in its native home. An important product of oak woods is the bark, formerly the chief tanning material of Europe. The acorns of the oak possess a considerable economic importance as food for swine. In the Saxon period the "mast" seems to have been regarded as the most valuable produce of an oak wood.

Of the European timber oaks, the next in importance to the British oak is *Q. Cerris*, the Turkey oak of the nurserymen. This oak abounds all over the Turkish peninsula, on the Taurus ranges, and in many parts of southern Europe; it was introduced into England about 1735, and is now common in parks and plantations.

The evergreen oak of southern Europe is *Q. Ilex*, usually a small tree, frequently of rather shrub-like appearance, with abundant glossy dark-green leaves, more or less prickly at the margin. The ilex, also known as the "holm oak" from its resemblance to the holly, abounds in all the Mediterranean countries. The stem sometimes grows 90 ft. in height, but it does not often reach a great size. In its native lands it attains a vast age; Pliny attributes to several trees then growing in Rome a greater antiquity than the city itself.

The cork oak, *Q. Suber*, the bark of which yields cork (*q.v.*), is a native of the west Mediterranean area. In Spain the wood is of some value, being hard and close-grained, and the inner bark is used for tanning.

The valonia of commerce, one of the richest of tanning materials, is the acorn of *Q. Aegilops*, a fine species indigenous to Greece and the coasts of the Levant.

Some oaks are of indirect importance from products formed by their insect enemies. Of these the Aleppo gall (*see GALLS*) is yielded by *Q. infectoria*, a native of Asia Minor and western Asia. *Q. coccifera*, a small bush growing in Spain and many countries around the Mediterranean, furnishes the kermes dye. (*See KERMES.*) *Q. persica*, or according to some *Q. mannifera*, attacked by a kind of *Coccus*, yields a sweet exudation which the Kurds collect and use as manna (*q.v.*).

In North America the oaks are generously represented. They attain their greatest size and economic importance in the southern United States, especially in the lower Mississippi valley, and reach their maximum diversity as regards species in the highlands of Mexico, notably in the western Sierra Madre range, where they form vast forests. In a recent monograph (*The American Oaks*, 1925), W. Trelease enumerates 371 species, of which 253 occur in Mexico, 54 in Central America, 3 in Panama, 4 in Colombia, and 1 in the Antilles (Cuba), while 84 are found in the United States, 10 extending into the southern border of Canada. These vary greatly in size from small, straggling or even creeping shrubs, to magnificent forest trees, 150 ft. or more in height, with trunks exceeding 6 ft. in diameter. In addition Trelease recognizes more than 50 named hybrid oaks whose parent species are regarded as satisfactorily determined.

The American oaks fall into two main groups—the white oaks and the red or black oaks—about equal in number and comprising practically all the species. In the white oak group (*Leucobalanus*) the acorns ripen at the end of the first season, the shell of the nut

is smooth inside, and the leaves or their lobes, which are usually rounded, are without bristle tips. In the black or red oak group (*Erythrobalanus*) the acorns ripen at the end of the second season, the shell of the nut is hairy inside, and the leaves or their lobes, which are usually sharp-pointed, have bristle tips.

Of the oaks found in the United States, upwards of 50 species attain the stature of trees, more than half of which are of economic value for timber or other useful purposes. Fully 20 species attain a height of 100 ft. or more, and 5 equal or exceed a height of 150 ft., with correspondingly massive trunks. These larger oaks constitute the chief supply of native hardwood lumber in North America. Three-fourths of them occur east of the Rocky Mountains; the others are found in the Pacific States, chiefly in California, the quality of their timber in general being inferior to that of the eastern oaks.

Among the most valuable eastern white oaks are the typical white oak (*Q. alba*), 80 ft. to 100 ft. high, with a trunk 3 ft. to 4 ft. in diameter, one of the finest North American trees; the rugged massive bur oak (*Q. macrocarpa*), sometimes 170 ft. high, with a trunk 6 ft. to 7 ft. in diameter; and the chestnut oak (*Q. montana*), the post oak (*Q. stellata*), the overcup oak (*Q. lyrata*), and the swamp chestnut or basket oak (*Q. Prinus*), all growing to a height of 100 ft. and highly valued for lumber. Noteworthy representatives of the eastern red or black oak group are the red oak (*Q. borealis*), sometimes 150 ft. high; the Shumard red oak (*Q. Shumardi*), 120 ft. high; the black oak (*Q. velutina*), 150 ft. high, and the somewhat smaller scarlet oak (*Q. coccinea*) and willow oak (*Q. Phellos*), all important timber trees.

The oaks of the Rocky Mountain region are mostly small trees, often becoming shrubby at the higher elevations. The Rocky Mountain white oak (*Q. leptophylla*), rarely 45 ft. high, is the largest Colorado oak, and the Arizona white oak (*Q. arizonica*), sometimes 60 ft. high, is the chief oak of New Mexico and Arizona.

In California some 15 species of oak occur. Among the deciduous kinds are the valley oak (*Q. lobata*), often 100 ft. to 125 ft. high, sometimes with a massive trunk 10 ft. in diameter; the Oregon white oak (*Q. Garryans*), 60 ft. to 100 ft. high, found from San Francisco bay to British Columbia, and the California black oak (*Q. Kelloggii*), sometimes 100 ft. high, found also in Oregon. Among the evergreen species are the coast live oak (*Q. agrifolia*) and the interior live oak (*Q. Wislizenii*), both medium-sized trees; the scrub oak (*Q. dumosa*), usually 2 ft. to 8 ft. high, abundant in the chaparral (*q.v.*), and the maul oak (*Q. chrysolepis*), sometimes branching into an immense crown 150 ft. across, and sometimes growing erect to a height of 110 feet.

The only evergreen species of the eastern States is the live oak (*Q. virginiana*), found near the coast from Virginia to Texas; it grows to a height of 75 ft., usually branching near the buttressed base into a round-topped head, sometimes 130 ft. across. The very strong wood was formerly much used in ship building.

The total cut of oak lumber in the United States in 1925 was 2,129,181,000 bd.ft., valued at the mill at \$78,779,698, 55% of which was cut in Arkansas, Tennessee, Louisiana, West Virginia and Mississippi. Commercially oak lumber is classified as white oak and red oak. White oak lumber is cut principally from the white, chestnut, post, bur, overcup and swamp chestnut oaks; red oak lumber is cut chiefly from the red, Shumard red, scarlet, black and willow oaks.

For world distribution *see* A. Engler and K. Prantl, *Die Natürlichen Pflanzenfamilien* (1887–1909); *see also* C. S. Sargent, *Manual of North American Trees* (2 ed., 1922); W. Trelease, "The American Oaks," *Mem. Nat. Acad. Sci.* v. xx. (1925); G. B. Sudworth, "Check List of the Forest Trees of the United States," *U.S. Dept. Agr. Mis. Cir.* 92 (1927).

OAKDALE, a city of Allen parish, Louisiana, U.S.A., in the south-western part of the State, on the Calcasieu river, and served by the Santa Fe and the Missouri Pacific railways. Pop. 4,016 in 1920 (33% negroes). It has lumber mills and other industries. The city was incorporated in 1923.

OAKHAM, a market town, and the county town of Rutland, England, 94 m. N. of London by the L.M.S.R. Pop. urban district (1921) 3,340. The church of All Saints ranges in style

from Early English to Perpendicular. Of Oakham castle, founded in the reign of Henry II., the Norman hall is used as the county hall. The manor came in the time of Henry II. into the hands of Walcheline de Ferrers, and subsequently passed to the earls of Winchelsea.

OAKLAND, a city of California, U.S.A., on the eastern shore of San Francisco bay, opposite San Francisco (3 m. distant) and facing the Golden Gate; the county seat of Alameda county and the third city of the State in size. It has a municipal airport of 825 ac.; is a port of call for 50 steamship lines; and is served by the Santa Fe, the Southern Pacific, the Western Pacific and electric railways, and by ferries and motor-coach lines. The population was 216,216 in 1920, of whom 49,895 were foreign-born, including 4,536 Chinese and Japanese, and was estimated locally at 342,000 in 1928. The business section of the city is built on a level crescent-shaped plain along the bay, averaging 2.5 m. in width, behind which gently sloping hills rise to an elevation of 1,500 ft., providing residential sections with magnificent views of the bay, with San Francisco and the Golden Gate directly opposite. The area of the city is 60.25 square miles. Adjoining it on the north is Berkeley; to the south, across an arm of the bay, is Alameda. These three cities and the seven smaller municipalities of the "Eastbay" district (Richmond, Emeryville, Piedmont, San Leandro, Albany, El Cerrito and Hayward) had a population of over 530,000 in 1928.

Parks, Museums and Schools.—In the heart of the city, surrounded by a park equipped as a general recreation centre, is Lake Merritt, a 160 ac. body of salt water. One part of the lake is a Federal refuge for birds, the regular winter resort of thousands of wild ducks. The city maintains 57 fully equipped playgrounds; public parks with an additional area of 628 ac.; and two municipal camps for week-end holidays and summer vacations, one in the high Sierras and the other on Feather river. There is a municipal auditorium seating 8,800 and a beautiful city-hall, both built since the World War. The public library contains 140,000 volumes. The city has an art gallery and three museums. The public-school system includes 44 elementary, 15 junior high and 8 high schools. The University of California, in Berkeley, is only 4 m. from the Oakland city-hall. In Oakland, on a 60 ac. campus in the foot-hills, is Mills college for women, opened in 1871 by Dr. Cyrus T. Mills and Mrs. Mills. Oakland is the seat also of St. Mary's college for men (Roman Catholic, 1863). Since 1910 the city has operated under a commission form of government.

Port Facilities and Commerce.—Oakland has 27 m. of water front. A channel has been dredged, and two large docks constructed. The railroads have built four solid filled moles and trestles, extending from the shore $1\frac{1}{2}$ to 3 miles. The commerce of Oakland Harbor (including the Alameda side of the inner harbour) was 3,217,897 tons in 1927, valued at \$200,325,445, of which \$14,690,794 represented exports to foreign countries, \$22,588,088 imports, \$81,854,793 coastwise receipts, \$60,363,075 coastwise shipments and \$20,828,695 local traffic.

Manufactures.—The industrial district lies just behind the water front and is traversed by 34 m. of main-line railroad track-age. Since the World War Oakland has had a great industrial expansion. In 1925 the Federal census of manufactures reported 602 establishments, with an aggregate output valued at \$144,840,830, five times the value for 1914. The motor-vehicles, bodies and parts manufactured in 1925 were valued at \$44,428,588, nearly $\frac{1}{3}$ the value of the total factory output. Next in importance were lumber and lumber products, electrical machinery, apparatus and supplies, canned and preserved fruits and vegetables, and boats and ships. There are four large shipbuilding plants.

History.—The site of Oakland was part of the holdings of Don Luis Maria Peralta, who received vast grants from the Spanish Crown. In 1842 he divided his lands among his four sons, and the two to whom this region fell established themselves on their estates. From one of them in 1850 Moses Chase leased a tract, and he became the founder of the future city. In 1852 the settlement was incorporated as a town and in 1854 it was chartered as a city. The name was suggested by the grove of oaks in which

the first houses were built. By 1860 it had a population of 1,543, which increased rapidly to 10,500 in 1870 and 34,555 in 1880.

OAKMONT, a residential borough of Allegheny county, Pennsylvania, U.S.A., on the Allegheny river and the Pennsylvania railroad, 12 m. N.E. of Pittsburgh. Pop. (1920) 4,512 (83% native white).

OAK PARK, a village of Cook county, Illinois, U.S.A., 9 m. W. of Chicago. It is served by the Chicago and North Western, the Chicago, Aurora and Elgin, and the Baltimore and Ohio Chicago Terminal railways. Pop. 39,858 (1920); estimated locally at 64,000 (1928). It is a residential suburb. The assessed valuation of property in 1926 was \$20,819,631. Incorporation, 1901.

OANNES (also IANNES, EUAHANES), in Babylonian mythology, the name given by Berossus to a mythical being who taught mankind wisdom. He is identical with the god Ea (*q.v.*), although there may not be any direct connection between the two names. Berossus describes Oannes as having the body of a fish but underneath the figure of a man. He is described as dwelling in the Persian gulf (Erythraean sea) and rising out of the waters in the day-time and furnishing mankind instruction in writing, the arts and the various sciences. Other epithets of Oannes are Annédotus, Odakön, Euedokus, Eneugamos, Eneuboulos, Anémentos. This antediluvian myth of a fish-like monster is based on the water god Enki of Eridu, patron of wisdom, symbolised as a "goat fish," and identified with Capricorn.

For the legend of Uttuku, or Tagtug, see S. Langdon, *Le Poème Sumerien du Paradis* (1919); *Revue d'Assyriologie*, vol. xxii., 32-38 (1925). On the biblical and other traditions concerning the revelation of all wisdom in the beginning before the Flood, see A. Jeremias, *Handbuch der Altorientalischen Geisteskultur* (Leipzig, 1913), 14-18, with references to literature. (S. L.)

OAR: see ROWING.

OAR-FISH, an oceanic fish, *Regalecus*, characterized by the long, compressed body, short head, large eye and long dorsal fin, forming a crest on the top of the head. The oar-fish is distinguished from its allies, the deal-fishes (*q.v.*) by the long filamentous pelvic fins ending in a spatulate expansion (hence their name). These fish reach a length of nearly 40ft.

OASIS, a fertile spot surrounded by desert (the Greek form is *oásos* which is doubtfully referred to the Coptic word *ouahe*, a dwelling place). On the desert Libyan plateau immediately west of the Nile between Aswan and Cairo are areas where the water comes to the surface or is found in shallow wells, e.g., Oases of Kharga, Dakhla and Farāfra. The water may come to the surface in springs, upon the artesian principle, or it may collect and remain in mountain hollows. These areas vary considerably in extent; they are always intensively cultivated, and support thick growths of date-palms; and all kinds of tropical vegetables, grains and small fruits are grown. Some oases have a large population with substantial dwellings, others are merely halting-places.

OASTLER, RICHARD (1789-1861), English reformer, was born at Leeds on Dec. 20, 1789, and in 1820 succeeded his father as steward of the Thornhills' extensive Fixby estates at Huddersfield, Yorkshire. In 1830 John Wood, a Bradford manufacturer, called Oastler's attention to the evils of child employment in the factories of the district. Oastler at once started a campaign against the existing labour conditions by a vigorous letter, under the title "Yorkshire Slavery," to the *Leeds Mercury*. After many years of agitation, in which Oastler played a leading part, the Ten Hours Bill and other Factory Acts were passed, Oastler's energetic advocacy of the factory-workers' cause procuring him the title of "The Factory King." In 1838, however, owing to his opposition to the new poor law and his resistance of the commissioners, he had been dismissed from his stewardship at Fixby; and, in 1840, being unable to repay £2,000 which he owed his late employer, Thomas Thornhill, he was sent to the Fleet prison, where he remained for over three years. From prison he published the *Fleet Papers*, a weekly paper devoted to the discussion of factory and poor-law questions. In 1844 his friends raised a fund to pay his debt, and on his release he made a triumphant entry into Huddersfield. Oastler died on Aug. 22, 1861.

See W. R. Croft, *The History of the Factory Movement, or, Oastler and his Times* (1888).

OAT, a cereal (*Avena sativa*) belonging to the family Gramineae or grasses. The genus *Avena* contains about 70 species mostly dispersed through the temperate regions of the Old World. The spikelets form a loose panicle, familiar in the cultivated oat, the flowering glume having its dorsal rib prolonged into an awn, which is in some species twisted and bent near the base.

Cultivated Oats.—The various cultivated oats seem to have been derived from the wild species, *A. fatua*, *A. sterilis* and *A. barbata*. *A. strigosa* is "the bristle-pointed oat." The white and black varieties of this species were cultivated on poor exposed land in Scotland. The "naked oat," *A. nuda*, was found by Bunge in waste ground about Peking; it was identified by the botanist Lindley with the pilcorn of the old agriculture; it was in cultivation in England in the 13th century. Both this and the "common oats," *A. vesca*, are described by Gerard. Parkinson tells us that in his time (early in the 17th century) the naked oat was sown in sundry places, but "nothing so frequent" as the common sort. The chief differences between *A. fatua* (wild oat) and the cultivated oat, are that in the former the chaff-scales which adhere to the grain are thick and hairy, and in the latter they are not so coarse and are hairless. The wild oat, moreover, has a long stiff awn, usually twisted near the base. In the cultivated oat it may be wanting, and if present it is not so stiff and is seldom bent. The grain is very small and worthless in the one, but larger and full in the other. The many varieties of the cultivated oat are included under two principal races—common oat or panicked oat with a spreading panicle, *A. sativa* proper, and Tatarian oats or banner oats which is often regarded as a distinct species, *A. orientalis*, with contracted one-sided panicles. With regard to the antiquity of the oat, A. de Candolle observes that it was not cultivated by the Hebrews, the Egyptians, the ancient Greeks or the Romans. Central Europe appears to be the locality where it was cultivated earliest, at least in Europe, for grains have been found among the remains of the Swiss lake-dwellings perhaps not earlier than the bronze age, while Pliny alludes to bread made of it by the ancient Germans. Pickering also records Galen's observations (*De Alim. Fac. i.* 14), that it was abundant in Asia Minor where it was made into bread as well as given to horses.

Besides the use of the straw when cut up and mixed with other food for fodder, the oat grain constitutes an important food for both man and beast. The oat grain (excepting the naked oat), like that of barley, is closely invested by the husk. Oatmeal is made from the kiln-dried grain from which the husks have been removed; and the form of the food is the well-known "porridge." In Ireland, where it is sometimes mixed with Indian-corn meal, it is called "stirabout." Groats or grits are the whole kernel from which the husk is removed. Their use is for gruel, which used to be consumed as an ordinary drink in the 17th century at the coffee-houses in London. The meal can be baked into "cake" or biscuit, as the Passover cake of the Jews; but it cannot be made into loaves in consequence of the great difficulty in rupturing the starch grains, unless the temperature be raised to a considerable height. With regard to the nutritive value of oatmeal, as compared with that of wheat flour, it contains a higher percentage of albuminoids than any other grain, viz. 12.6—that of wheat being 10.8—and less of starch, 58.4 as against 66.3 in wheat. It has rather more sugar, viz. 5.4—wheat having 4.2—and a good deal more fat, viz. 5.6, as against 2.0 in flour. Lastly, salts amount to 3.0% in oat, but are only 1.7 in wheat. Its nutritive value, therefore, is higher than that of ordinary second flour.

Economically, the oat ranks as one of the most valuable cereals. In 1925 the total world production, exclusive of Russia and China, was estimated at 3,957,000,000 bu. of 32 lb. each, of which the United States contributed 1,502,529,000 and Canada, 513,384,000. Germany yielded 384,737,000 bu.; France, 327,645,000; Poland, 228,145,000; and the United Kingdom, 206,878,000. (*See OATS: Cultivation and Trade.*)

For details see A. de Candolle, *Origin of Cultivated Plants* (1884); W. W. Robbins, *Botany of Crop Plants* (Philadelphia, 1924); J. Percival, *Agricultural Botany*, (7th ed., 1926).

OATES, TITUS (1649–1705), English conspirator, was the son of Samuel Oates (1610–1683), an Anabaptist preacher, chap-

lain to Pride, and afterwards rector of All Saints' Church, Hastings. On leaving Cambridge he took Anglican orders, and officiated in several parishes, Hastings among them. Having brought malicious charges in which his evidence was rejected, he narrowly escaped prosecution for perjury. He next obtained a chaplaincy in the navy, from which he was speedily dismissed. He now applied for help to Dr. Israel Tonge, a rector who was obsessed with the idea of Roman Catholic plots; Oates was to help him in unravelling the plots. To this end it was decided that Oates should pose as a Catholic. He spent some time at the Jesuit colleges of Valladolid and St. Omer, being expelled from both.

Returning in June 1678 to Tonge, he forged a plot by piecing together things true and false, or true facts falsely interpreted, and by inventing treasonable letters and accounts of preparations for military action. The whole story was written by Oates in Greek characters, copied into English by Tonge, and finally told to one of Charles II.'s confidential servants named Kirkby. Kirkby having given the king his information, Oates was sent for. He gave details, in 43 articles, of the plot and the persons who had engaged to assassinate Charles. Charles at no time believed this incredible farrago. To bolster up the case a fresh packet of five forged letters was concocted; but the forgery was transparent, and even Sir William Jones, the attorney-general, though a violent upholder of the plot, dared not produce them as evidence.

Oates now made an affidavit before Sir Edmond Berry Godfrey (*q.v.*) to an improved edition of his story, in 81 articles. Among the persons named was Coleman, secretary to the duchess of York, whom Godfrey knew, and to whom he sent word of the charges. Coleman in turn informed the duke, who induced Charles to compel Oates to appear before the privy council. Here Oates was exposed by a few simple questions. But among the papers seized at Oates's request were Coleman's, and in them were found copies of letters written to Père la Chaise, suggesting that Louis should furnish him with money, which he would use in the French and Catholic interest among members of parliament. Among them, too, were these passages: "Success will give the greatest blow to the Protestant religion that it has received since its birth"; "we have here a mighty work upon our hands, no less than the conversion of three kingdoms, and by that perhaps the utter subduing of a pestilent heresy, which has so long domineered over great part of the northern world." The credit of Oates was thus, in the eyes of the people, re-established, and Coleman and others named were imprisoned.

On Oct. 12, occurred the murder of Godfrey. On Oct. 21, parliament met, and Oates was called before the House. A new witness was wanted to support Oates's story, and in November a man named William Bedloe came forward. At first he remembered little; by degrees he remembered everything that was wanted. Oates then accused the queen before Charles of high treason, and carried his tale before the House of Commons. The Commons voted for the queen's removal from court, but, the Lords refusing to concur, the matter dropped. It was not, however, until 1679 that the slaughter of Jesuits and other Roman Catholics upon Oates's testimony and that of his accomplices was checked. Sir George Wakeman, the queen's physician, was accused of purposing to poison the king, and the queen was named as being concerned in the plot. Sir Philip Lloyd proved Oates to have perjured himself, and Wakeman was acquitted. On June 26, 1680, upon Oates's testimony, the duke of York was presented as a recusant at Westminster. But the panic had worn itself out, and Oates retired on a pension. Shortly before the death of Charles, James brought, and won, a civil action against Oates, with damages of £100,000; in default of payment Oates was taken to prison; while there he was indicted for perjury, and was tried in May 1685, soon after the accession of James II. He received a severe sentence with repeated floggings, which was expected to kill him, but to the astonishment of all he survived.

Oates was in prison for three and a half years. Finally he received a royal pardon, with a pension of £300 a year. The remainder of his life was spent in retirement, varied by sordid intrigue. In 1691 he became acquainted with William Fuller, whom he induced to forge another plot, though not with the success he

had himself attained. In 1696 he dedicated to William III. a book called *Eikon Basilike*, a tissue of invective against "the late king James." In 1698 he obtained admission as a member of the Baptist Church, and used to preach at Wapping; but in 1701, as the result of a financial scandal, he was formally expelled from the sect. He died on July 12, 1705.

Lingard's *History* gives an exhaustive and trustworthy account of the Popish terror and its victims; and the chief incidents in Oates's career are graphically described by Macaulay. On the question of the place of his education see *Notes and Queries* (Dec. 22, 1883). See also T. Seccombe's essay in *Twelve Bad Men* (1894, bibliography).

OATH (O. Eng. *ādah*), an asseveration or promise made under non-human penalty or sanction. The word is found throughout the Teutonic languages, but without ascertainable etymology.

Retribution for Violation (see DYNAMISM).—The harm or penalty consequent on perjury may be considered to result directly, without any spirit or deity being mentioned. Thus among the Nagas of Assam, two men will lay hold of a dog or a fowl by head and feet, which is then chopped in two with a single blow of the dao, this being emblematic of the fate expected to befall the perjurer. Or a man will take hold of the barrel of a gun, a spear-head or a tiger's tooth, and solemnly declare, "If I do not faithfully perform this my promise, may I fall by this!" (Butler in *Journ. Asiatic Soc., Bengal*, 1875, p. 316).

In Siberia, in lawsuits between Russians and the wild Ostiaks, it was usual to bring into court the head of a bear, the Ostiak making the gesture of eating, and calling on the bear to devour him in like manner if he does not tell the truth. Similar oaths are sworn on the head or skin of a tiger by the Santals and other indigenous tribes of India. Death by a tiger precludes reincarnation and therefore involves social and physical extinction. Both in the old and modern world oaths by rivers are most sacred. In earlier ages men swore inviolably by Styx or Tiber, and an oath on water of the Ganges is to the Hindu the most binding of pledges, for the goddess will take awful vengeance on the children of the perjurer. The Tungus brandishes a knife before the sun, saying, "If I lie may the sun plunge sickness into my entrails like this knife."

The transition to invoking gods conceived in human form is shown in the treaty-oath between the Macedonians and the Carthaginians recorded by Polybius (vii. 9); here the sun and moon and earth, the rivers and meadows and waters, are invoked side by side with Zeus and Hera and Apollo, and the gods of the Carthaginians. The heaven-god, able to smite the perjurer with his lightning, was invoked by the Romans, when a hog was slain with the sacred flint representing the thunderbolt, with the invocation to Jove so to smite the Roman people if they broke the oath (Liv. i. 24; Polyb. iii. 25). But bears and tigers are as apt to kill truth-tellers as perjurers, and the lightning-flash falls without moral discrimination. In the *Clouds* of Aristophanes, the Socrates of the play points out that notorious perjurers go unharmed, while Zeus hurls his bolts at his own temple and the tall oaks, as if an oak-tree could perjure itself.

The doctrine of miraculous earthly retribution on the perjurer lasted on in legend, as where Eusebius relates how three villains conspired to bring a false accusation against Narcissus, bishop of Jerusalem, which accusation they confirmed by solemn oath before the church, one wishing that if he swore falsely he might perish by fire, one that he might die of the pestilence, one that he might lose his eyes; a spark no man knew from whence burned to ashes the first perjurer's house and all within, the second was consumed by the plague from head to foot, whereupon the third confessed the crime with tears so copious that he lost his sight (Euseb. *Hist. Eccl.* vi. 9). In general the supernatural retribution on perjury has been transferred to beyond the grave.

International Forms.—Gestures such as grasping hands, or putting one hand between the hands of another in token of homage, are not oaths, but ceremonies of compact. Even the covenant among many ancient and modern nations by the parties mixing their blood or drinking one another's is in itself only a solemn rite

of union, not an oath proper.

The act of swearing by weapons may signify that the swearer if forsworn is to die by such a weapon; or the warrior may appeal to his weapon as a powerful or divine object (see Du Cange, *s.v.* "Juramenta super arma"; Grimm, *Deutsche Rechtsalterth.*, p. 896). Stretching forth the hands towards the object or deity is a natural gesture, used by Israelites (Gen. xiv. 22; Deut. xxxii. 40; see Dan. xii. 7; Rev. x. 5). In France a juror takes oath by raising his hand, saying, "Je jure!" The Scottish judicial oath is taken by the witness holding up his right hand uncovered, and repeating after the usher, "I swear by Almighty God, and as I shall answer to God at the great day of judgment, that I will," etc.

In the ancient world sacrifice (*q.v.*) often formed part of the ceremony of the oath; typical examples may be found in the Homeric poems. Details of the old Scandinavian oath have been preserved in Iceland in the *Landnámabók* (*Isleendinga Sögur*, Copenhagen, 1843); a bracelet (*baugr*) of two rings or more was to be kept on the altar in every head court, which the god or priest should wear at all law-things held by him, and should reddén in the blood of the bullock sacrificed, the witness pronouncing the remarkable formula: "Name I to witness that I take oath by the ring, law-oath, so help me Frey, and Niörd, and almighty Thor" (*hialpi mer svá Freyr, ok Miördr, ok hinn almáttki Áss*), etc. This was doubtless the great oath on the holy ring or bracelet which the Danes swore to King Alfred to quit his kingdom.

Under Christ's injunction, "Swear not at all" (Matt. v. 34; also James v. 12), many Christians have shrunk from taking oaths, see writings of the Fathers. In more modern times Anabaptists, Mennonites and Quakers have refused to take even judicial oaths. On the other hand, the laws of Christendom from early ages have been directed against such swearing as was considered profane or otherwise improper, and against perjury. Constantine's laws required every witness in a cause to take oath; this is confirmed in Justinian's code which even in some cases requires also the parties and advocates to be sworn (*Cod. Theod.* xi. 39; *Justin. Cod.* iv. 20, 59). Bishops and clergy were called upon to take oath in ordination, monastic vows, and other ecclesiastical matters (see details in Bingham, *Antiq. of Chr. Church*, xvi. 7). The Reformation conformed to this principle in Art. xxxix. of the church of England. The Christian oath on a copy of the Gospels seems derived from the late Jewish oath taken holding in the hand the scroll of the law (or the phylacteries), a ceremony itself possibly adapted from Roman custom (see treatise "Shebuoth" in *Gemara*). The practice of kissing the book, established in England, appears in the middle ages (J. E. Tyler, *Oaths*, pp. 119, 151). The book was often laid on the altar, or the swearer laid his hand on the altar itself, or looked towards it; or touched relics of saints on the altar. Other objects, as the cross, the bishop's crosier, etc., were sworn by (see Du Cange, *s.v.* "Jurare"). An oath ratified by contact or inspection of a sacred object was called a "corporal" or bodily oath, as distinguished from a merely spoken or written oath.

Oath Formulas.—Among the oath formulas used in Christendom, that taken by provincial governors under Justinian is typical of one class: "I swear by God Almighty, and His only begotten Son our Lord Jesus Christ, and the Holy Ghost, and the Most Holy Glorious Mother of God and ever Virgin Mary, and by the Four Gospels which I hold in my hand, and by the Holy Archangels Michael and Gabriel," etc. The famous oath of the kings Louis and Charles at Strassburg in A.D. 842 runs: "By God's love and the Christian people and our common salvation, as God shall give me knowledge and power," etc. In the oath of fealty in the capitularies of Charlemagne in 802, is found the familiar form "Sic me adjuvet Deus," corresponding to formulas of pre-Christian Rome. This became widely spread in Europe, appearing in Old French "Si m'ait Dex," German "So mir Gott helfe," English "So help me God." A remarkable point in its history is its occurrence in the "So help me Frey," etc., of the old Scandinavian ring-oath already described. William the Conqueror swore "by the splendour of God," Richard I. "by God's legs," John "by God's teeth"; other phrases are given in Du Cange as "per omnes gentes," "per coronam," "par la sainte figure de Dieu," "par la mort Dieu," etc.

Law.—In England the coronation oath is administered by an archbishop or bishop in the presence of the people, who, on their parts, reciprocally take the oath of allegiance to the crown. *The archbishop or bishop shall say:* "Will you solemnly promise and swear to govern the people of this United Kingdom of Great Britain and Ireland and the dominions thereto belonging according to the statutes in parliament agreed on, and the respective laws and customs of the same?" *The king shall say:* "I solemnly promise so to do." *Archbishop or bishop:* "Will you to the utmost of your power cause law and justice, in mercy, to be executed in all your judgments?" *King:* "I will." *Archbishop or bishop:* "Will you to the utmost of your power, maintain the laws of God, the true profession of the Gospel, and the Protestant reformed religion established by law? And will you maintain and preserve inviolably the settlement of the Church of England and the doctrine, worship, discipline and government thereof, as by law established in England? And will you preserve unto the bishops and clergy of England, and to the churches therein all such rights and privileges as by law do or shall appertain to them, or any of them?" *King:* "All this I promise to do." *After this the king, laying his hand upon the holy Gospels, shall say:* "The things which I have here before promised I will perform and keep; so help me God," and then shall kiss the book. (See CORONATION.)

The chief officers of state take an "official" oath well and truly to serve his majesty. Special oaths are taken by privy councillors, archbishops and bishops, peers, baronets and knights, recruits and others. The old oath of allegiance, as administered (says Blackstone, *Commentaries*, book i. chap. x.) upwards of 600 years, was replaced in the reign of William III. by a shorter form; and it now runs: "I . . . do swear that I will be faithful and bear true allegiance to His Majesty . . . , his heirs and successors, according to law." Statutes of Charles II. and George I. enacted that no member should vote or sit in either house of parliament without having taken the several oaths of allegiance, supremacy and abjuration. In modern times a single parliamentary oath was substituted for the three, and this was altered to enable Roman Catholics to take it; Jews were enabled to sit in parliament by being allowed to omit the words "on the true faith of a Christian." In its present form the parliamentary oath consists of an oath of allegiance and a promise to maintain the succession to the crown as limited and settled in the reign of William III. The right to affirm in lieu of taking the parliamentary oath was first raised in the case of Charles Bradlaugh (*q.v.*).

The "judicial" oath taken by judges of the court of appeal or of the High Court of Justice, and by justices of the peace, is "to do right to all manner of people after the laws and usages of this realm, without fear or favour, affection or ill-will." Jurors are sworn, whence indeed their name (*iuratores*); in felonies the oath administered is: "You shall well and truly try and true deliverance make between our sovereign lord the king and the prisoner at the bar whom you shall have in charge, and a true verdict give according to the evidence." (See *JURY*.) The oath of the jurors in the Scottish criminal courts is: "You [the jury collectively] swear in the name of Almighty God and as you shall answer to God at the great day of judgment that you will truth say and no truth conceal in so far as you are to pass upon this assize." In the ancient custom of compurgation, once prevalent in Europe, the accused's oath was supported by the oaths of a number of helpers or compurgators who swore to their belief in its validity.

Witnesses in English law courts must give their evidence under the sanction of an oath, or of what is equivalent to an oath, and the ordinary form of oath adapted to Christians is: "The evidence you shall give . . . shall be the truth, the whole truth, and nothing but the truth. So help you God." Many alterations of the English law as to oaths have been made in relief of (1) those Christians who object on conscientious grounds to the taking of an oath, and (2) of those persons who refuse to admit the binding force of an oath. Special provision was first made for Quakers, Moravians and Separatists; then followed general enactments relating to civil and criminal proceedings respectively, till finally the law was embodied in the Oaths Act 1888, which enacted that "every person upon objecting to being sworn, and stating, as the

ground of such objection, either that he has no religious belief, or that the taking of an oath is contrary to his religious belief, shall be permitted to make his solemn affirmation instead of taking an oath." . . . The form of affirmation prescribed by the Oaths Act was as follows: "I, A. B., do solemnly, sincerely, and truly declare and affirm," etc. Under s. 5 of the same act a person might swear in the Scottish form, with uplifted hand (no book of any kind being used) and if he desired to do so "the oath shall be administered to him in such form and manner without question." With the desire of making universal the method of administering the oath the Oaths Act 1909 was passed. A Christian swears on the Gospels, holding a copy of the New Testament in his uplifted right hand, the hand being uncovered, and his head being also uncovered. A witness may elect to be sworn on any version of the Bible which he considers most binding on him, as a Roman Catholic on the Douai Testament or Bible. A Jew is sworn on the Pentateuch, holding a copy thereof in his right hand, the head being covered. A Mohammedan is sworn upon the Koran. He places his right hand flat upon the book and puts the other hand upon his forehead, bringing his head down to the book and in contact with it. He then looks at the book for some moments. Buddhists are sworn on the Buddhist doctrines, Sikhs upon the Granth, Parsees upon the Zend Avesta, Hindus upon the Vedas, or by touching the Brahmin's foot, and, according to caste custom, Indian witnesses sometimes insist upon the oath being administered by a Brahmin; but in India witnesses now generally affirm. Kafir witnesses swear by their own chief, and a Kafir chief by the king of England. When a Chinese witness is to be sworn, a saucer is handed to him which he takes and, kneeling down, breaks into fragments.

The administering or taking of unlawful oaths is criminal in English and Scots law. Statutes relating to the offence were passed in 1797, 1799, 1810 and 1812, and it is evident from the preamble of the latter act (Unlawful Oaths Act 1812) that they were aimed at those societies in the United Kingdom at the time of the French Revolution which required or permitted their members to take an unlawful oath. Supplementary statutes were passed in 1817 and 1837. Children of tender years, who, in the opinion of the court, have not sufficient intelligence to understand the nature of an oath, may give evidence without being sworn.

United States.—In the United States oaths required by way of qualification for public office or citizenship are generally prescribed by constitutions or statutes. At an early date provisions were made for simple affirmation for the benefit of those whose religious faith proscribed the taking of an oath. Witnesses in the law courts or before legal or administrative officials invested with the power of administering oaths must give their evidence under oath or by affirmation. Belief by the witness in a God and an appeal to him as an avenger of falsehood are the essentials of the oath. Liberal allowances may thus be made for the taking of oaths by non-Christians, the witness being sworn in such fashion as he considers binding on his conscience. Professed atheists have on occasion been excluded from the witness stand, but generally the religious belief of a witness can only be used to impeach his credibility. No special form need accompany the administration of an oath, unless required by statute, provided that some formal act be done to impress the witness with the distinction between sworn statements and bare assertions.

OATS: CULTIVATION AND TRADE. Oats are the principal cereal crop in Great Britain, their acreage in England and Wales exceeding that of wheat by one-fifth and in other parts of the kingdom by a still greater margin.

The oat is a comparatively hardy, robust plant and is adaptable to a wide range of soils. Although not immune to the effects of soil acidity, oats may be grown with success on land that is too sour for barley or wheat, and it is a common crop on peaty soils. The heaviest yields of grain are obtained either where the soil is moist, as in fen districts, or where the summer rainfall is ample, as in the western counties. Lack of moisture induces premature

grain formation. Too much moisture, on the other hand, causes excessive growth of straw with a tendency to lodging and uneven or late ripening.

Although there are seven species in the genus *Avena*, all the varieties of oat grown in this country belong to the species *sativa* and its sub-species *sativa orientalis*, which comprises such sorts as Tartarians, whose panicle is one-sided instead of being open as in the main group. Hunter classifies the numerous varieties of open-headed oats in five groups:—1. Winter hardy oats (Grey Winter, Black Winter, etc.); 2. Semi-hardy sorts (Black Bell, Mogul, etc.); 3. Potato division (Potato, Sandy, etc.); 4. Abundance division (Abundance, Victory, Golden Rain); and 5. Early ripeners (Aurora, Sixty Day, etc.).

Winter varieties are preferred to spring sorts in dry, warm localities, where frit fly is troublesome on oats sown after mid-March; they also ripen early and favour autumn cleaning operations preparatory for root crops. Grey winters are somewhat hardier and are more suitable for poor soils than Blacks, but the latter are capable of higher yields on better land and are less liable to lodging. White winter oats are not sufficiently hardy to be considered a reliable winter-sowing sort, but they do very well for February and even January sowing.

Oats are very adaptable in the matter of crop sequence: they may follow any crop in the rotation, and are the favourite first-crop on reclaimed or broken up grass land. The soil preparations for oats are of the simplest description: the land is ploughed about 5 in. deep some time during the winter, usually January, and nothing more is done until the soil is dry enough to receive the seed in spring. In humid districts, broadcasting is still common, but elsewhere the seed is usually drilled; the seed is advisedly covered rather more deeply than other cereals, 2 in. to 3 in. being the proper depth. Thorough harrowing and, when the soil is dry enough, heavy rolling complete the cultivations for the crop. It is not customary to apply manure to the oat crop, except a little nitrogenous top dressing where the soil is poor.

Early sowing—March, or even February with hardy varieties—is desirable to avoid frit fly attack, but successful results may attend April sowing in more humid districts. Typically 170–200 lb. of seed are sown per acre, but with very large grained sorts or in hill farming, heavier seeding is believed to be beneficial. Winter oats are drilled at lighter rates, typically 120 lb. per acre, and October is the normal month for sowing.

Winter oats are generally ready for cutting in the latter half of July, and spring sown varieties about the second week in August. Owing to their tendency to shed grain, oats are advisedly cut rather before they would be dead ripe. Generally the crop is ready for stacking after ten days drying in stooks. The average yield per acre is 14 cwt. of grain and about 20–25 cwt. of straw.

Most of the oats grown in Great Britain are used on the farms for feeding to live stock, but of the 2 to 2½ million tons produced annually about 600,000 to 650,000 tons are sold off the farms and are purchased mainly for feeding to town horses, poultry, etc., and for the making of oatmeal.

Average Annual Imports of Oats

Countries from which consigned	1909–13	1922–26
	Tons	Tons
Argentina	282,000	130,000
Chile	30,000	29,000
Germany	120,000	5,700
Rumania	30,000	2,600
Russia	287,000	2,500
United States	38,000	99,000
Total Foreign Countries*	802,000	284,000
Canada	72,000	142,000
New Zealand	21,000	1,300
Total British Countries*	98,000	170,000
Total	900,000	454,000

*Includes imports from countries not named.

In the years 1922–26 imports of oats averaged about 454,000

tons per annum, about 284,000 tons coming from foreign countries and 170,000 tons from Empire countries overseas. Much smaller quantities are now imported than formerly, the average annual imports in 1909–1913 being about 900,000 tons, and even in the seventies of the nineteenth century the average annual imports were 600,000 tons. The reduction in imports as compared with the five years before the World War is wholly in imports from foreign countries, more being received from British countries.

(J. R. B.; H. C. L.)

Cultivation in the United States.—Oats are grown to some extent in almost all parts of the United States, but principally in a belt extending westward from New York to North Dakota and south to the latitude of the mouth of the Ohio river. Most crops in the United States are spring-sown, fall sowing being practised only in the South. The date of fall seeding varies from Sept. 15 to Nov. 15, according to the locality, while the date of spring seeding varies from January to May, in like manner. Oats are seeded broadcast or with a grain drill, the latter method being preferable.

Oats are sometimes grown in combination with other crops for the production of hay or grain and are used as a nurse crop for clover and grass and as a cover crop in orchards. They are very useful likewise for clearing land of weeds. Oats are frequently grown in rotation with corn and grass or clover in the North, and with cotton and corn in the South. Where new land is being brought under cultivation, oats are usually grown on old land, corn, or sorghum, wheat or flax being more commonly grown on sod land.

Oats Trade of the United States.—Oats enter into commerce much less than wheat because they are too bulky in relation to price to bear the burden of long distance transportation. The production of oats in the United States in the past five years has averaged about 1,300 million bushels of which about one-fourth has entered into commerce. The bulk of oats production is north of the area of maize production. Minneapolis and Chicago are the most important primary markets. St. Louis, Omaha and Milwaukee are also important markets. The bulk of the oats crop is consumed by animals in the United States. Only about 3% is for human consumption. Very little of the crop is exported.

Oats, as well as corn and wheat, moving into interstate commerce, are subject to inspection by the Federal Government. For commercial purposes there are four classes, namely, white, red, grey and black oats. (O. C. S.)

OAXACA (wah-hab'ka) or **OAJACA** (officially **OAXACA DE JUÁREZ**), a southern State of Mexico, including the southern and larger part of the Isthmus of Tehuantepec. Pop. (1900) 948,633, (1910) 1,040,398, (1920) 1,159,789, a large majority of whom are Indians. The State has an area of 35,382 sq. m. broken by mountain ranges into numerous broad fertile valleys, chiefly lying in the *tierra templada* region. The isthmus districts, however, have lower elevations and are distinctly tropical. The coast line is 329 m. long; behind it is a narrow strip of lowlands lying within the *tierras calientes*. In places this strip nearly disappears, the sierras rising almost immediately from the seashore. The highest points are Zempoaltepetl (11,145 ft.), San Felipe del Agua (10,253 ft.), and the Cerro del Leone, the highest summit in the Sierra Madre del Sur. The only ports on the coast open to foreign trade are Salina Cruz and Puerto Mexico—the first, the Pacific terminus of the Tehuantepec railway, with a spacious artificial harbour, and the second a deep but narrow natural harbour, the coast terminus of the Tehuantepec National railway. The greater part of the State has a sub-tropical climate, with high sun temperatures, moderate rainfall and mild, healthful conditions. The less healthful regions include the isthmus districts, the coastal zone on the Pacific and the low country near Vera Cruz. The chief products are Indian corn, wheat, coffee, sugar, rubber, cotton, cacao, tobacco, indigo and a great variety of tropical fruits. Among the manufactured products are cotton, woollen and "pita" fibre fabrics, sugar, rum, mescal, beer, furniture, pottery, soap, candles, leather, matches, chocolate, flour and cigarettes. Two important railway lines traverse the State—the Tehuantepec National (trans-isthmus) and the Mexican Southern line (narrow-

gauge) from Puebla to Oaxaca. Two progressive Indian races, the Zapotecas and Mixtecas, descendants of those who built the remarkable cities of Mitla and Monte Alban (see CENTRAL AMERICA: Archaeology) form the greater part of the population.

OAXACA or **OAXACA DE JUÁREZ** (official title) (from Aztec *Huaxyacac*), capital of the Mexican State of Oaxaca. Pop. (1921) 27,792, largely Indians, most of whom are Mixtecas and Zapotecas. Oaxaca is connected with Puebla (211 m.) by the Mexican Southern railway. The city lies in a broad, picturesque valley 5,085 ft. above sea-level, and has a mild temperate climate. It has a fine old cathedral in the Spanish Renaissance style and dating from 1553; rebuilt in 1702.

According to tradition the Aztec military post and town of Huaxyacac was founded in 1486. The date of the first Spanish settlement is uncertain, but it was probably between 1522 and 1528. The city suffered severely in the earthquakes of 1727 and 1787, the cathedral being greatly damaged in 1727. In war and revolution, it has been repeatedly captured.

OB or **OBI**, river of Asiatic Russia, known to the Ostiaks as the *As*, *Yag*, *Kolta* and *Yema*; to the Samoyedes as the *Kolta* or *Kuay*; and to the Tatars as the *Omar* or *Umar*. Its length is roughly 2,400 m.; the area of its basin is considerably more than a million sq.m. and the navigable waters in its basin total more than 17,000 m. Its source is in the Altai mountains and its course is through hilly country to the Kirghiz steppe and thence it flows to its delta in the gulf of Ob, an inlet of the Arctic ocean 600 m. in length. In its middle course, south of its junction with the Irtysh, and extending between the two streams, are the Vasuigan swamps, named from the Vasuiga, a left bank tributary of the Ob. They extend for 100,000 sq.m. and in summer are impassable marshes, with dense thickets of cedars, larches and pines. In spring they are flooded and are then known as the Vasuigan sea. In winter they become ice-bound and may be crossed. When drained the land proves fertile. North of the swamps the river flows through coniferous forest to Berezhov, and passes Obdorsk, where there is a Veterinary Institute for the help of the reindeer breeders and to which small sea-going vessels can penetrate.

After receiving its largest tributary, the Irtysh, the Ob divides into more than one arm and is of little use for navigation except for barges bringing fish from the delta in the autumn. Above the junction of the Irtysh, steamers and barges ply upon the Ob and its tributaries the Irtysh, the Tobol, the Tavda and the Tura in summer. In 1915 there were 350 steamers and several hundred barges chiefly carrying corn, flour, salt and timber, in addition to passengers. The east-west river traffic is giving place to railway communication, but the north-south route is still very important. The river is frozen from November to May or June; floods, ice and floating timber impede navigation for some time after the thaw.

The fact that in its southern parts the Ob approaches so close to the Yenisei that short and easy portages link them, made the penetration of Siberia by the Cossacks an easy task. The Chulim, a tributary of the Ob, in its upper course is at one point only six m. from the Yenisei, but a canal link is impossible owing to the great difference in level, while the Ket river, another right bank tributary of the Ob has canal communication with the Kas, a tributary of the Yenisei.

The Irtysh, which is quite as important as the Ob, rises as the Black Irtysh, south of the Mongolian border, and flows through the Dzungarian gate into Russia, where it expands into Lake Zaisan, and then cuts its way across a spur of the Altai into the plains. There are lakes, many of which are salt and are rapidly drying; flourishing villages stand on the site of what in the early part of last century was Lake Chany.

OBADIAH, the fourth of the "minor prophets," the otherwise unknown author of the shortest book in the Old Testament, whose 21 verses, even, show evidence of the expansion or addition of which a manuscript, as distinct from a printed book, so easily admits. Whilst the first fourteen verses address Edom in the second person singular, with apparent reference to recent disasters that have befallen that people, the last six address Israel

in the second person plural, promising judgment on the nations, including Edom, and proclaiming the eschatological "Day of Yahweh," when the lost territories shall be recovered. (The "join" is made in verse 15, of which *a* belongs to the latter, and *b* to the former, prophecy.) The Edomites (identified with "Esau," verse 6; cf. Gen. xxxvi. 1) occupied the mountainous country south of the Dead Sea, on both sides of the Arabah; hence the reference to their rock-dwellings (verse 3). The aid which they gave to the Babylonians against Jerusalem in 586 (Ps. cxxxvii. 7, etc.) was never forgiven, and its remembrance inspires the present prophecy (verses 11ff.). The actual disaster that befell the Edomites was probably some invasion by the neighbouring nomads, e.g., the Nabatean Arabs (verse 7). The opening paragraph of Malachi may refer to the same event; if so, we may suppose the prophecy of Obadiah in its earlier part to belong to the first half of the fifth century B.C. The dominant thought of it is that at last Edom has received its deserts at the hand of Yahweh. We do not know at what date this earlier portion was continued and incorporated into the more general prophecy concerning the future vindication of Judah, with which the book now closes. The original prophecy has elsewhere been reproduced, as well as expanded. Its first five verses occur in almost the same form in Jer. xlix. 14-16 & 9 (cf. also Joel ii. 32), a passage probably later than Obadiah. See **EDOM**.

OBAN, burgh and seaport, Argyllshire, Scotland, 113 m. N.W. of Glasgow by L.M.S., and about the same distance by water. Pop. (1921) 6,344. Its bay is screened by the island of Kerrera and sheltered by hills to the north and east. The Roman Catholic pro-cathedral was erected by the 3rd marquis of Bute. Oban, a government fishing station in 1786, is now the centre of tourist traffic for western Argyllshire and the islands.

At the north end of the bay stands the ruin of Dunolly Castle, the old stronghold of the Macdougalls of Lorne, whose modern mansion adjoins it. In the grounds is a huge conglomerate rock called the Dog Stone (*Clach-a-choin*), from the legend that Fingal used to fasten his favourite dog Bran to it. About 3 m. N.E. are the ruins of Dunstaffnage Castle. It was here that the "Stone of Destiny," now contained in the base of the coronation chair at Westminster Abbey, was kept before its removal to Scone.

OBLIGATO or **OBLIGATO**, in the modern sense, a musical term for an instrumental accompaniment to a musical composition which, while in one way independent, is included by the composer on purpose and in a prescribed form, instead of being left to the discretion (*ad libitum*) of a performer.

OBEDIENT-PLANT (*Physostagia virginiana*), a North American herb of the mint family (*Labiatae*), called also false dragon-head and lion's-heart, native to moist soil from Quebec to Ontario and Minnesota, and south to Florida and Texas. It is an erect, smooth, usually unbranched perennial, 1 to 4 ft. high, bearing oblong or lance-shaped, sharply-toothed, pointed leaves and dense terminal clusters (spikes) of pale-purple, rose-coloured or sometimes white flowers, about 1 in. long. The flower displays the peculiar characteristic of remaining temporarily at whatever angle it may be placed with reference to the stem.

OBELISK, a form of monumental pillar; and also the term for a bibliographical reference-mark in the form of a dagger. The typical Egyptian obelisk is an upright monolith of nearly square section, generally ten diameters in height, the sides slightly convex, tapering upwards very gradually and evenly, and terminated by a pyramidion whose faces are inclined at an angle of 60°. Obelisks were usually raised on pedestals of cubical form resting on one or two steps, and were set up in pairs in front of the entrance of temples. Small obelisks have been found in tombs of the Old Kingdom. The earliest temple obelisk still in position is that of

Senwosri I. of the XIIth Dynasty at Heliopolis (68 ft. high). A pair of Rameses II. (77 and 75 ft. high respectively) stood at Luxor until one was taken to Paris in 1831. Single ones of Tethmosis I. and Hatshepsut still stand at Karnak and remains of others exist there and elsewhere in Egypt. Colossal obelisks were erected by only a few kings, Senwosri I. in the Middle Kingdom and Tethmosis I., Hatshepsut, Tethmosis III. and Rameses II. of the Empire. Smaller obelisks were made in the Saïte period. The Romans admired them, and the emperors carried off some from their original sites and made others in imitation (e.g., that for Antinous at Benevento); 12 are at Rome, one in Constantinople; two, originally set up by Tethmosis III. at Heliopolis, were taken by Augustus to adorn the Caesareum at Alexandria: one of these, "Cleopatra's Needle," was removed in 1877 to London, the other in 1879 to New York. The pyramidions were sheathed in bright metal, reflecting the sun's rays as if they were thrones of the sunlight. They were dedicated to solar deities, and were especially numerous at Heliopolis, where there was probably one of immemorial antiquity sacred to the sun. The principal part of the sun-temple at Abusir built by Neuserre of the Vth Dynasty appears to have been in the shape of a stumpy obelisk on a vast scale; only the base now remains, but hieroglyphic pictures indicate this form. The hieroglyph of some other early sun-temples

shows a disc on the pyramidion . The material employed for the great obelisks was a pink granite from Syene, and in these quarries there still remains, partially detached, an example 70 to 80 ft. long. The largest obelisk known is that in the piazza of St. John Lateran at Rome, set up by Tethmosis III. at Heliopolis in the 15th century B.C. and brought from Egypt by Constantine the Great and erected in the Circus Maximus, being ultimately re-erected in 1552 by Pope Sixtus V. It was 105 ft. 9 in. high, including the pyramidion, and its sides measured 9 ft. 10 in. and 9 ft. 8 in. respectively. On the base of the obelisk of Hatshepsut at Karnak, 97 ft. 6 in. high, there is an inscription stating that it and its fellow were made within the short space of seven months.

There was another form of obelisk, also tapering, but more squat than the usual type, with two of the sides narrow and terminating in a rounded top. One such of Senwosri I., covered with sculpture and inscriptions, lies at Ebgig in the Fayum.

In Abyssinia, at Axum and elsewhere, there is a marvellous series of obelisk-like monuments, probably sepulchral. They range from rude menhirs a few feet high to elaborately sculptured monoliths of 100 feet. The loftiest of those still standing at Axum is about 60 ft. high, 8 ft. 7 in. wide, and about 18 in. thick, and is terminated by a rounded apex united by a necking to the shaft. The back of the obelisk is plain, but the front and sides are subdivided into storeys by a series of bands and plates, each storey having panels sunk into it which seem to represent windows with mullions and transom. These architectural decorations are derived from a style of building as found by a German expedition extant in an ancient church; courses of stone here alternate in the walls (both inside and out) with beams of wood held by circular clamps. In front of the best-preserved obelisk is a raised altar with holes sunk in it apparently to receive the blood of the sacrifice to the ancestors. Most of these must date before the adoption of Christianity as the State religion in the 6th century.

OBELISK (KARNAK)

See G. Maspero, *L'Archéologie égyptienne* (new ed., 1907); H. H. Goringe, *Egyptian Obelisks* (New York, 1882; London, 1885, etc.); F. W. von Bissing and L. Borchardt, *Das Re-Heiligtum des Königs Ne-wosser-Re* (1905); on the ancient method of raising obelisks, L. Borchardt, "Zur Baugeschichte des Amonstempel von Karnak," in *Sethe's Untersuchungen zur Geschichte und Altertumskunde Aegyptens*, vol. xv. For the Abyssinian obelisks see especially E. Littmann and D. Krencker, *Vorbericht der deutschen Aksum Expedition* (1906). (F. Ll. G.)

OBERAMMERGAU, a village of Bavaria, Germany, situated among the foot-hills of Kofel mountains, a range of the Alps, in the Ammer valley, 64 m. S.S.W. of Munich. Pop. about 1,700. The outside walls of many of the houses are decorated with fresco paintings, reproductions of famous biblical masterpieces. The villagers make toys and pottery, and carve wooden crucifixes, rosaries and images of saints. These carvings are shipped to all parts of the world and are found in many churches.

THE OBERAMMERGAU PASSION PLAY

The village is famous for its performance of a Passion play every ten years. This is probably the most important survival of

A VIEW OF THE VILLAGE OF OBERAMMERGAU, SITUATED IN THE MOUNTAINS OF BAVARIA

the miracle plays so popular from the 13th to the 16th century. Contrary to popular belief, this production is not a portrayal of the life of Christ, but only of the events of his last few days on earth, known as Passion week.

In 1633 the village was stricken with the scourge of the Black Death. As an expression of gratitude for the cessation of the scourge the inhabitants vowed to enact the Passion and death of Christ every ten years. The first performance was given in 1634 and repeated every ten years until 1674, after which the dates were changed so as to fall on decimal years. This now has been faithfully kept with the exception of 1870, when the Franco-Prussian War interfered. The earliest extant text of the play was written in 1662, probably by the monks of Ettal, a monastery situated a few miles from Oberammergau. The text is slightly revised every ten years. The music was composed by Rochus Dedler, a schoolmaster of the parish, in 1814. The initial performance of the play is given the first Sunday in May, and is repeated every Sunday, with two or three extra performances each week. On account of the unsettled conditions resulting from the World War the 1920 production was postponed until 1922, during which year it was played 61 times. It starts at eight o'clock in the morning and continues for eight hours, with a short intermission at noon. The characters are chosen by a committee made up of the village priest, burgomaster, village council and members selected by popular vote. No one may participate in the spectacle unless he is a native of the village and is of unimpeachable moral character and dramatically qualified to enact the rôle for which he is chosen. Over 700 characters participate in the play. This includes the orchestra of 50 members and the chorus of 46. It is estimated that more than 300,000 witness the production each season. The proceeds are divided into four equal parts: one for the preparation of the play, one for the furnishing of homes for the visitors, one for the church and one for the players.

The play is enacted on a large open-air platform, the audience occupying an auditorium with a capacity of about 6,000, viewing the play through an immense oval opening in front of the auditorium. The play consists of 18 acts and a number of tableaux. Each act is prefaced by an orchestral selection and a choral anthem giving the motif of the act. This, in turn, is followed by

a tableau based on the Old Testament prefiguring the theme of the act. For instance, the scene depicting the Crucifixion is preceded by a tableau representing the offering of Isaac as a sacrifice by Abraham. The chief characters are the Christus, the Twelve Disciples, Mary the mother of Jesus, Mary Magdalene and Martha. Anton Lang holds the distinction of portraying the part of the Christus for three decades, 1900, 1910 and 1922. The participants regard their rôles with religious devotion and enact their parts with the deepest reverence. In the years intervening between the representations of the play performances are given of many classics for the purpose of training the prospective players for the Passion play, in enunciation, stage bearing and all other requirements of dramatizing. No wigs or facial make-up are permitted. The costumes, however, are of the biblical period and are of the very best material. The participants train their hair and beards and study to assume the general appearance of the characters for which they are candidates. (W. E. V.)

OBERHAUSEN, a town in the Prussian Rhine province, 5 m. from the east bank of the Rhine, 20 m. N.E. of Düsseldorf, on the main railway line to Hanover and Berlin, and at the centre of an important network of lines radiating hence into the Westphalian coal and iron fields. Pop. (1925) 105,135. The first houses of Oberhausen were built in 1845, and it received its municipal character in 1874. The town has large iron-works, coal-mines, rolling-mills, zinc smelting-works, dye-works, railway workshops and manufactures of wire-rope, glass, chemicals, sugar, porcelain and soap.

OBERLIN, a village of Lorain county, Ohio, U.S.A., 34 m. W.S.W. of Cleveland, on Federal highway 20, and served by the New York Central lines and electric railways. Pop. (1920) 4,236. It is a pleasant residential village, the seat of Oberlin college and other educational institutions. Since 1926 it has had a manager form of government. Oberlin college was founded in 1833 by the Rev. John J. Shipherd (1802-44) and Philo P. Stewart (1798-1868), and was named after Jean Frédéric Oberlin (d. 1826), the Alsatian pastor and philanthropist. Its educational plant is valued (1928) at about \$4,700,000; its endowment funds aggregate \$16,000,000; the library has about 300,000 bound volumes; and the student body numbers 1,800. Oberlin college includes the Graduate School of Theology, and the Conservatory of Music.

The "Oberlin Theology" (not now identified with the college) centred in the teachings of President Finney, a powerful preacher and teacher, who carried on remarkable revival services in eastern cities of America and in England and Scotland. The modern theological position of the college is reflected in the writings of Emeritus President King and of the late Dean Edward I. Bosworth of the theological seminary (1861-1927). Oberlin was the first American college to adopt co-education, and in Aug. 1841, three women were regularly graduated from the classical course—the first women in America to receive the degree of bachelor of arts on conditions like those prevailing in the best men's colleges of the time. Oberlin was also a pioneer (1835) in refusing to debar students on account of race. A substantial proportion of the students earn part of their expenses.

Oberlin was a "station" on the Underground Railroad. The attic of President Finney's home frequently sheltered slaves who were escaping to Canada. In 1858 a runaway slave, Littlejohn, was captured in Oberlin by a U.S. marshal, and was rescued at Wellington (10 m. S.) by a band of Oberlin professors and others, in consequence of which 30 professors were arrested and imprisoned. This was a famous fugitive slave case. The village was founded as a home for the college, and was incorporated in 1846. The Anti-Saloon League was here started in 1893.

OBERON, king of the elves. In the legendary history of the Merovingian dynasty he is a magician, brother of Merowech (Mérové). In the *Nibelungenlied* he guarded the treasure of the Nibelungen. In the German mediaeval poem of *Ortmit*, the hero is aided in his wooing by his father Alberich, the king of the dwarfs. As Oberon, king of the fairies, he fills a similar rôle in *Huon of Bordeaux* (q.v.). Shakespeare used the fairy element in *A Midsummer Night's Dream*, and Wieland in his epic *Oberon*

(1780). Ben Jonson wrote a masque of *Oberon, or the Fairy Prince* (Works, 1616). Weber's opera, *Oberon*, to the words of J. R. Planché, was first produced at Covent Garden in 1826. See also C. Voretzsch, *Epische Studien. Die Kompositionen des Huon von Bordeaux* (Halle, 1900).

OBITER DICTUM, that which is said by the way; specifically, in law, an opinion expressed by a judge incidentally in the course of a case, on a point of law not material to the issue or to the grounds of the decision; such *obiter dicta* have no binding authority.

OBJECT and **SUBJECT**, in philosophy, the terms used to denote respectively the external world and consciousness. The term "object" is used generally in philosophy for that in which an activity of the mind ends, or towards which it is directed. With these may be compared the ordinary uses of the term for "thing" simply, or for that after which one strives, or at which one aims. "Subject," is originally the material or content of a discussion or thought, but in philosophy is used for the thought or the thinking person. The relation between the thinking subject and the object thought is analogous to the grammatical antithesis of the same terms: the "subject" of a verb is the person or thing from which the action proceeds, while the "object," direct or indirect, is the person or thing affected. The true relation between mind or thought (subject) and matter or extension (object) is the chief problem of philosophy, and may be investigated from various standpoints (see *PSYCHOLOGY* and *METAPHYSICS*).

OBJECTIVISM, in philosophy, a term used, in contradistinction to **SUBJECTIVISM**, for any theory of knowledge which to a greater or less extent attributes reality (as the source and necessary pre-requisite of knowledge) to the external world. The distinction is based upon the philosophical antithesis of the terms Object and Subject, and their respective adjectival forms "objective" and "subjective." In common use these terms are opposed as synonymous respectively with "real" and "imaginary," "practical" and "theoretical," "physical" and "psychic." A man "sees" an apparition; was there any physical manifestation, or was it merely a creation of his mind? If the latter the phenomenon is described as purely subjective. Subjectivism in its extreme form denies that mind can know more than its own states. Objects, i.e., things-in-themselves, may or may not exist: the mind knows only its own sensations, perceptions, ideal constructions and so forth. In a modified form "subjectivism" is the philosophic theory which attaches special importance to the part played by the mind in the accumulation of experience. See *PSYCHOLOGY* and related articles.

OBLATE, an ecclesiastical term for persons not professed monks, friars or nuns, who have devoted themselves or have been devoted as children by their parents to a religious life. "Oblate" is more familiar in the Roman Church as the name of a religious congregation of secular priests, the Oblate Fathers of St. Charles. This congregation was founded in 1578 under the name of Oblates of the Blessed Virgin and St. Ambrose by St. Charles Borromeo, archbishop of Milan (see *BORROMEO, CARLO*). There is a similar congregation of secular priests, the Oblates of Mary the Immaculate, founded at Marseilles in 1815. See the *Catholic Encyclopaedia*, s.v. "Oblate."

OBLATION, an offering, a term, particularly in ecclesiastical usage, for a solemn offering or presentation to God. It is thus applied to certain parts of the Eucharistic service in the Roman Church. There are "two oblations," the "lesser oblation," in which the bread and wine yet unconsecrated are presented after the offertory, and the "greater oblation," the "oblation" proper, forming the latter part of the prayer of consecration, when the "Body and Blood" are ceremonially presented. See the *Catholic Encyclopaedia*, s.v. "Oblation."

OBLIGATION, in law, a term derived from the Roman law, in which *obligatio* signified a tie of law (*vinculum iuris*), whereby one person is bound to perform or forbear some act for another. The *obligatio* of Roman law arose either from voluntary acts or from circumstances to which legal consequences were annexed. In the former case it was said to arise from contract, in the latter

from tort, or from acts or omissions to which the law practically attached the same results as it did to contract or tort. *Obligatio* was used to denote either end of the legal chain that bound the parties, the right of the party who could compel fulfilment of the *obligatio*, the *creditor*, or the duty of the party who could be compelled to fulfilment, the *debitor*. In English law obligation has only the latter sense. Creditor and debtor have also lost their Roman law signification; they have been narrowed to mean the parties where the obligation is the payment of a sum of money. But in legal systems, chiefly founded on Roman law, the original meanings remain. In English law obligation is used in at least four senses—(1) any duty imposed by law; (2) the special duty created by a *vinculum juris*; (3) not the duty, but the evidence of the duty—that is to say, an instrument under seal, otherwise called a bond; (4) the operative part of a bond. The third and fourth uses of the word are chiefly confined to the older writers. The party bound is still called the obligor, the party in whose favour the bond is made the obligee. The word "bond" is, of course, a mere translation of *obligatio*. Obligations may be either perfect or imperfect. A perfect obligation is one which is directly enforceable by legal proceedings; an imperfect or moral obligation (the *naturalis obligatio* of Roman Law) is one in which the *vinculum juris* is in some respects incomplete, so that it cannot be directly enforced, though it is not entirely destitute of legal effect.

American law is in general agreement with English. The term obligation is important in the U.S.A. from its use in art. i. s. 10 of the constitution, "No state . . . shall pass any . . . law . . . impairing the obligation of contracts." This does not affect the power of Congress to pass such a law.

OBOE or HAUTBOY. The treble member of the class of wood-wind instruments having a conical bore and a double reed mouthpiece, the oboe consists of a conical wooden tube, composed of three joints, upper, middle and bell, and of a short metal tube to which are bound by many turns of waxed silk the two thin pieces of cane that form the mouthpiece. These pieces of cane are so bevelled and thinned at the end which is taken into the mouth that the gentlest stream of compressed air suffices to set them vibrating and thereby to set up the rhythmical series of pulses which generate the sound waves in the stationary column of air within the main tube of the instrument.

The compass of the oboe is from B flat below the treble staff to F in alt, or even a note or two higher, with all chromatic semitones. Its quality of tone is thin, penetrating and even somewhat nasal. It is possible to play on it diatonic and chromatic scale and arpeggio passages, legato and staccato; leaps; cantabile passages; sustained notes, crescendo and diminuendo, grace notes and shakes (with reservations).

The first appearance of the instrument in a musical work occurs in Sebastian Virdung's *Musica getutscht und aussgezogen* (1511). It there bears the name of *Schalmey*, and is already associated with an instrument of similar construction called *Bombardt*. There exists, however, much earlier evidence, in the illuminated mss. and in the romances of the Middle Ages, of the great popu-

BY COURTESY OF CARL FISCHER, INC., NEW YORK
THE OBOE IN ITS MODERN FORM

larity of the instrument in all parts of Europe. The oboe was known during the early Middle Ages as *Calamus*, *Chalumeau* (France), *Schalmey* (Germany) and *Shawm* (England), while after the Renaissance we find instruments of this type ranged in complete families from the soprano to the bass and known respectively as the little *Schalmey*; the discant *Schalmey*; the alto *Pommer*; the tenor *Pommer*; the bass *Pommer*; and the great double quint *Pommer*.

The 17th century brought no great changes in the construction of the four smaller instruments of the family. Extensively used

in France, they were there called "haulx bois" or "haut-bois," to distinguish them from the two larger instruments which were designated by the words "gros bois." Hautbois became hautbois in French, and oboe in English, German and Italian; and this word is now used to distinguish the smallest instrument of the family still in use.

The reform in the construction of the flute due to Theobald Boehm of Munich about 1840, a reform which principally consisted in the rational division of the tube by the position of the lateral holes, prompted Triebert to try to adapt the innovation to the oboes and bassoons; but he failed, because the application of the system denaturalized the timbre of the instruments, which it was necessary, before all things, to preserve. Further improvements, however, made upon the same lines by Barret and later by Rudall Carte, have transformed the oboe into the most delicate and perfect of reed instruments, as which it constitutes one of the most valuable and indispensable members of the modern orchestra.

OBOK, a seaport on the north shore of the Gulf of Tajura, N.E. Africa, acquired by France in 1862. It gave its name to the colony of Obok (now French Somali coast protectorate). (See SOMALILAND: *French*.) The port is separated from the open sea by coral reefs, but is only partially sheltered from the winds. The French in 1896 transferred to Jibuti, on the opposite shore of the Gulf, the seat of government of the colony. Obok is connected with Aden and Jibuti by submarine cables. It is only a native village with a population of about 300.

OBRECHT, JACOB (also HOLBRECHT) (c. 1430–c. 1500), Dutch composer, was born probably at Utrecht about 1430. About 1474 Erasmus was under him as a choir boy at Utrecht, where he was chapel master, and in the same year Obrecht seems to have held an appointment at Ferrara. He was afterwards director of the Cambrai school of singing, and at some time lived in Florence, where his name is associated with Josquin, Isaac and Africola, and the musicians who clustered round Lorenzo's court. The principal records of his later years are found in Antwerp Cathedral, where he was chapel master from 1491 until his death. That he possessed immense contrapuntal skill and was considered one of the greatest masters of the age there is evidence in the praise of his contemporaries and successors, the honours bestowed upon him, and the visits received by him at Antwerp. The finest of his eight masses, *Fortuna Desperata*, was published in Amsterdam (1870) and appears in 1880 in the *Maatschappij tot Bevordering der Toonkunst* (No. ix.). He also wrote chansons and motets. The finest of the motets is *Salve crux arbor vite*. Great interest attaches to his *Passion*, in which the chorus impersonates all the characters in the story and the narrative is given to the tenor in recitative.

A definitive edition of his works has been published by Johannes Wolf (*Werke van Jacob Obrecht*, Amsterdam and Leipzig).

OBREGÓN, ALVARO (1880–1928), Mexican soldier and president, was born in the district of Alamos, Sonora, on Feb. 17, 1880. During his early life as a planter he became an advocate of land reforms to better the condition of the peons and Indians, and in 1912 he entered the services of Madero, a man of similar ideals. With Indian troops which he recruited, Obregon aided in suppressing the revolt of Orozco against Madero, and later he again took the field against Felix Diaz whose successful revolt led to the downfall of Madero and the establishment of Huerta as provisional president. Obregon then joined the counter-revolution of Carranza who had remained true to Madero. After a string of victories culminating in the successful storming of Sinaloa and Culiacan and the capture of Guadalajara, the way to Mexico City was opened, and on Aug. 15, 1914, Obregon led the Carranza troops into the capital. Huerta fled.

In the struggle which arose between Carranza and Zapata and Villa, Obregon remained loyal to Carranza. He defeated Zapata finally at Pueblo in Jan. 1915. In April he conducted a campaign against Villa for the control of central Mexico and by winning the battles of Celaya and Leon forced Villa back to his mountain fastnesses. As leader of the radical wing of Carranza's followers and chief of the army, Obregon possessed power enough to force into the new Constitution of 1917, against Carranza's wishes, the

famous article 27 which provided for the restoration of communal lands to the Indian villages, limited the size of individual land holdings, deprived religious organizations of the right to hold lands and reserved to the Government the ownership of all mineral and petroleum resources. The new Constitution also provided that no president should succeed himself, but in 1920 Carranza took steps to have himself retained in power, one of these steps being an order for the arrest of Obregon. Obregon escaped to Sonora where a revolt against Carranza was already in progress and put himself at the head of the troops. In a short time he was master of the situation and on Dec. 1, 1920, was elected president. He immediately adopted a friendly tone toward the United States and other foreign countries, and in 1923 the United States recognized his Government. His administration was made notable by many labour and agrarian reforms and by a sincere effort to carry the provisions of the 1917 Constitution into force. In 1924 he supported Calles, his minister of the Interior, for president. His opponents under de la Huerta charged fraud in the election and started a revolution. Obregon once more took the field, defeated the rebels and drove de la Huerta into exile. Obregon was again elected president on July 1, 1928, but on July 17 before taking office he was assassinated.

He wrote *Ochomil kilómetros en Campaña* (1917). See also J. A. Tamayo, *El Gral. Obregón y la guerra* (1922); E. J. Dillon, *President Obregón, a World Reformer* (1922); H. I. Priestly, "Calles and Obregón," *California University Chronicle*, vol. xxx. (1928).

OBRENOVIĆ, the name of a dynasty which supplied several rulers of Serbia in the 19th century. See MILOŠ OBRENOVIĆ; MICHAEL; MILAN; and ALEXANDER.

O'BRIEN, WILLIAM (1852–1928), Irish patriot, was born at Mallow, Co. Cork, on Oct. 2, 1852, son of James O'Brien, a solicitor's clerk. He was educated at the Cloyne diocesan college and at Queen's college, Cork, and began journalism in 1869 on the *Cork Daily Herald*. In 1875 he joined the staff of the *Free-man's Journal*. In 1880 he founded his own paper, *United Ireland*, conducted with amazing vigour. Forster, on reading the first number, is said to have exclaimed, "Who is this new madman?" O'Brien's paper was suppressed for the time being, and he was shut up in Kilmainham gaol, with Parnell and others. There O'Brien drew up the famous "No Rent" manifesto, which was smuggled out of Kilmainham, read at a Land League meeting in Dublin, and led to the proclamation of the league as an illegal association.

After Forster's recall from Ireland, O'Brien resumed his campaign in *United Ireland*. In 1887, under the Balfour régime in Ireland, O'Brien started the slogan of "no reduction, no rent." For this "plan of campaign" see IRELAND: History. Parnell was much out of Ireland, and though he eventually disavowed the "plan," O'Brien had stirred up a fierce agitation, met by the British Government with the Coercion Act of 1887. Under this act O'Brien was sent to Tullamore gaol. He had been elected M.P. for Mallow in 1883, and on his release he appeared in the House of Commons to renew his obstructive tactics there.

After the Parnell divorce case he tried to mediate between the Parnellites and the anti-Parnellites. He advised the retirement of Parnell until the storm should have blown over. Finally in 1900 he reunited the party. In 1903 O'Brien, who had begun his career as a land agitator, thought that the Wyndham Land Act of 1903 offered a bridge between the Nationalists and the southern Unionists. He wanted an "act for Ireland" party which should include men of all creeds and of various opinions. He split the Irish Party, and in the general election of 1918 his followers retired, leaving a clear fight at the polls between the Nationalists and the Sinn Feiners. Thus the man who had sought conciliation with southern Unionists in 1903 was fated, though he had no faith in Sinn Fein methods, to secure the Sinn Fein victory.

O'Brien married a French woman, Sophie Raffalovich, the daughter of a Paris banker. He died on Feb. 26, 1928.

O'BRIEN, WILLIAM SMITH (1803–1864), Irish revolutionary, was born in Co. Clare on Oct. 17, 1803, and educated at Harrow and at Cambridge. He took the additional name of Smith on inheriting his maternal grandfather's estates in Limerick. He entered parliament in 1828 as member for Ennis, and from

1835 to 1848 represented the county of Limerick. Although he spoke in 1828 in favour of Catholic emancipation, he differed on other points from the general policy of O'Connell. But he opposed the Irish Arms act of 1843, and became an active member of the Repeal association. In July 1846 the "Young Ireland" party, with Smith O'Brien and Gavan Duffy at their head, left the Repeal association, and in the beginning of 1847 established the Irish Confederation. In May 1848 he was tried at Dublin for sedition, but the jury disagreed. In the following July he established a war directory, and attempted to make a rising among the peasantry of Ballinacorney, but the movement lacked cohesion, and the crowd dispersed before the approach of the dragoons. O'Brien was arrested at Thurles, tried and sentenced to death. The sentence was, however, commuted to transportation to Tasmania for life. In May 1856 he obtained a full pardon, and returned to Ireland. He died at Bangor, North Wales, on June 18, 1864.

OBSCENITY. By English common law it is an indictable misdemeanor to give an obscene exhibition or to publish any obscene matter, whether it be in writing or by pictures, effigy or otherwise. The precise meaning of "obscene" is, however, decidedly ambiguous. It has been defined as "something offensive to modesty or decency, or expressing or suggesting unchaste or lustful ideas or being impure, indecent or lewd."

Besides the remedy by indictment there are statutory provisions for punishing as vagabonds persons who expose to public view in public streets or adjacent premises obscene prints, pictures or other indecent exhibitions. These are supplemented by the Indecent Advertisements Act 1889, which was passed to suppress indecent advertisements. By the Obscene Publications Act 1857 powers are given for searching premises on which obscene books, etc., are kept for sale, distribution, etc., and for ordering their destruction, and the post office authorities have power to seize postal packets containing such matter and to prosecute the sender under the Post-Office Act.

The use of obscene or indecent language in public places is punishable as a misdemeanor at common law, but it is usually dealt with summarily, under the Metropolitan Police Act 1839, or the Town Police Clauses Act 1847, or under local by-laws.

In the United States, the different States provide punishment for obscene libel, the exhibition of obscene pictures and the display or use of obscene language in public. The Federal Government penalizes sending of obscene matter through the mails.

Indecent acts committed with intent to insult females are punishable under the Vagrancy Act 1824 as amended by sect. 42 of the Criminal Justice Act 1925, and if committed otherwise under the Acts of 1839 and 1847. (W. DE B. H.)

OBSERVATORY (ASTRONOMICAL). The erection of special buildings adapted to the pursuit of astronomical research is a practice of long standing.

FROM THE EARLIEST TIMES TO 1800

It is said by Diodorus that the great temple of Belus at Babylon was built for astronomical purposes, and, since there is indication in the Chinese records that the gnomon was used for measuring the height of the sun in the reign of the emperor Yao (2300 B.C.) it may be said that the beginning of practical astronomy was contemporaneous in Eastern and Western Asia. There is no evidence of the existence of an observatory of Greek or Alexandrine origin until the time of Ptolemy Soter, who, about 300 B.C., built one at Alexandria. The earliest records from an observatory known to be extant are those of Hipparchus (c. 140 B.C.) who has left a catalogue of stars from observations made at the island of Rhodes, repeating those made earlier at Alexandria. Three hundred years later, Ptolemy (A.D. 150) compiled a star catalogue, but it is doubtful whether this was from his own observation and, therefore, whether he had an observatory beyond that at Alexandria.

The art of astronomical observation was revived several hundred years later in Western Asia when observatories were established at Damascus and Baghdad and one at Mokatta by Caliph Hakim about A.D. 1000. A splendid observatory was built at Maragha in north-west Persia by Hulagu Khan about A.D. 1260,

but the most productive was that of the Persian Prince Ulugh Beigh, grandson of the great Tamerlane, who, at Samarcand with his assistants, made a catalogue of stars from observations with a large quadrant in the first half of the 15th century. Later in that century, about 1471, John Müller of Königsberg, better known as Regiomontanus, set up an observatory at Nuremberg, with the help of Bernard Walther of that city, furnished with instruments of his own design, and after his death in 1476, clocks, then a recent invention, were added to the equipment, but the first observatory that may be considered a prototype of modern national observatories was that of Tycho Brahe on the island of Hveen. Here, on Aug. 8, 1576, there was laid the foundation stone of a building to serve as a residence and an observatory to which he gave the appropriate name Uranibourg.

Tycho Brahe's Observatory.—This building was of some magnificence and large enough to house Tycho and several young men who lived with him as students or observers. It was furnished with a large quadrant attached to a wall in the plane of the meridian, for to this astronomer is due the credit of appreciating the advantage of size in instruments of this type, and of the principle which is embodied in the mural circle. Here Tycho Brahe lived in some state, with a dwarf as jester among his small retinue, for 20 years, and with his assistants, one of whom was Longomontanus, a name well known in the science, observed the heavens and produced a catalogue of the position of more than 1,000 stars. On the death of his patron, Frederick II. in 1588, Tycho was deprived of royal favour and income. In 1597 Tycho left Denmark, the observatory at Hveen having been already dismantled.

The invention of the telescope in 1609 opens a new chapter in the history of observatories, and the first of a new class may be taken to be the building at Padua from which Galileo made the first observation of Jupiter's satellites on Jan. 8, 1610. Others were created as additions to universities or similar institutions during the 17th century, an observatory called the "Tower of the Winds" having been established at the Vatican by Gregory XIII., the Pope who gave his name to the Gregorian Calendar, and another attached in 1632 to the university at Leyden, that had been in existence for half a century. In 1637, King Christian IV of Denmark, established a permanent observatory at Copenhagen which was completed 20 years later and then placed under the direction of Longomontanus. It exists in some form at the present date.

John Hevel, or Hevelius, a member of a noble family of Danzig, built an observatory in 1641 in his own house and furnished it with an azimuthal quadrant of 5 ft. radius and a sextant of 6 ft., with which he measured the meridian altitudes of stars, sun, moon and planets, and their distances from one another in the manner of Tycho—that is, with plain sights, believing this to be superior to the newly adopted telescopic method.

Paris, Greenwich and Others.—Hevelius died early in 1687 and his work was not carried on, but by that date there had come into existence the two national observatories at Paris and Greenwich. The former was built in the years 1667–71, according to the plans of Claude Perrault, as an architectural monument. However, under Cassini and others, it has done much for astronomy. The Royal Observatory, Greenwich, was founded in 1675 for the definite purpose of the improvement of navigation. Architectural pride again entered into the design, for Sir Christopher Wren wrote of it to Bishop Fell of Christ Church, Oxford, as built "a little for pomp" referring to the main building. The essential instruments were housed apart from this, and at the present time, Wren's beautiful creation is merely a small item in its extensive domain.

Few establishments of the kind were erected during the next half century. Newton placed his telescope on the roof of the tower over the gateway of Trinity college, Cambridge, and his contemporary, and perhaps rival, Leibnitz, is said to have originated at Berlin university in 1705 an observatory of similar modest dimensions, that became of importance more than 100 years later. The year 1751 is assigned as the date of foundation of the observatory at Göttingen which was supplied by George II. of

England with a mural quadrant of 6 ft. radius made by the Englishman, Bird, and in charge of Tobias Mayer. It was re-established in another situation in 1816. Induced mainly by the occurrence of the transit of Venus in 1769, George III. built and furnished the King's Observatory at Kew. The improvement in reflecting telescopes by Short and the invention of the achromatic object glass in the latter part of the 18th century marked the beginning of many observatories that have since become famous. The Radcliffe observatory at Oxford was erected 1771–74 from funds bequeathed by Dr. Radcliffe, a Court physician "for charitable purposes," the words being interpreted somewhat widely. Provost Andrews bequeathed a substantial sum for building and endowing an astronomical observatory for the University of Dublin, which was built at Dunsink in 1783, but not furnished with instruments until many years later. At the charge of Primate Robinson an observatory was established and endowed at Armagh in Ulster in 1793, whilst the most prolific British observatory of the period was that of William Herschel at Bath, Datchet and Slough successively.

Early Continental Observatories.—Continental observatories established during this period were those of Mannheim (1775), which was transferred to Karlsruhe in 1880, and again to Heidelberg in 1896; Lillienthal founded by Schroter in 1779, and furnished with a reflector made by Herschel; Leipzig where a small observatory existed on the tower of the university in the years 1787–90; Breslau (1790); also one at Seeberg near Gotha, founded by Duke Ernest II. in 1788 that was made famous by Zach and Encke. The observatory at Palermo, Sicily, where Piazzini made his famous catalogue of stars, was founded in 1790; and at about the same time Lalande and his assistants were observing transits of stars from an observatory in l'Ecole Militaire, Paris.

THE NINETEENTH CENTURY

British Observatories.—A full list of observatories, public and private, founded in Great Britain during this next 100 years would be large. An observatory on Calton Hill, founded by a private association, the Edinburgh Astronomical Institution, in 1818, was taken over by the Crown as a Royal Observatory in 1834, and transferred to its present site on Blackford Hill in the years 1889–96 (*see* Plate). Cambridge university observatory was founded in 1820 and under its noted directors, Airy, Challis, Adams, Ball and Eddington has done valuable work, and now well equipped with instruments, has a solar and astrophysical observatory. The Radcliffe observatory at Oxford was originally in the charge of the Savilian professor of astronomy but this arrangement lapsed and the offices of professor and Radcliffe Observer became distinct about 1839. In 1875 the University observatory came into existence largely through the liberality of Warren De la Rue, for the use of the Savilian professor. The work of this observatory has been largely photographic. An observatory was established at Liverpool mainly for the time service of the port in 1838, and at Glasgow a small observatory attached to the university of which Dr. Alexander Wilson had been the first director about 1760, was enlarged and transferred to a new site in 1836.

As to private observatories, that of Stephen Groombridge at Blackheath (about 1802) was merely an apartment in his dwelling-house, containing a transit circle with which he made a star catalogue that has taken a notable place in fundamental astronomy. Another that achieved notoriety was that of James South, a London surgeon, who set up an observatory in south London in 1816 which he removed to Kensington. Admiral Smyth at Bedford and Dr. Lee at Hartwell were two well-known astronomers who had establishments of the kind about the year 1830. Mr. E. J. Cooper, a young enthusiast in astronomy, established an observatory in 1831 at Markree castle, Sligo, for which he bought a 13 in. object glass by Cauchoix, then the largest in the world, and supplied it with other notable instruments. With the help of assistants, work was carried on at this observatory until Mr. Cooper's death in 1863. The reflecting telescope with 6 ft. mirror made by Lord Rosse and set up at his seat, Parsonstown, Ireland, in 1845, is famous, and scarcely less so are the smaller instruments of the

same type made by William Lassell, and used by him at Liverpool 1844-52. Another observatory of the period was that of Mr. George Bishop at South Villa, Regent's Park, which had as its principal instrument an equatorially-mounted, clock-driven telescope of 7 in. aperture, which was used for discovering and observing small planets and other work by Dawes, Hind, etc.

At his observatory established at Redhill in 1852 Mr. Richard Carrington made a catalogue of the positions of circumpolar stars, and a record of sunspots which are both works considered classic in the science.

Observatories established in England in the second half of the 19th century were those of De la Rue, a pioneer in astronomical photography, at Cranford in Middlesex; of George Knott at Cuckfield, Sussex; of William Huggins, the famous spectroscopist, at Tulse Hill, the private observatory of Norman Lockyer, who afterwards developed spectroscopic research at a state-supported establishment at South Kensington. Those of Crossley at Halifax, Yorkshire, and Espin at Towlaw, Durham, have reputations based on double-star observations, whilst the observatory at Dunecht, established by Lord Lindsay, heir to the earl of Crawford and Balcarres in 1871, which endured for about ten years, is perhaps most remembered for having introduced David Gill into the astronomical world. At present (1929) there are a dozen private observatories in England, perhaps of smaller pretensions outwardly, but each used by its actual owner for some chosen line of work.

Colonial Observatories.—A feature of the 19th century was the establishment of British Colonial observatories. Acting on the proposal of the Board of Longitude in 1820, the Lords Commissioners of the Admiralty resolved to establish an observatory at the Cape of Good Hope for the improvement of practical astronomy, which came into being in the year 1829, and has adequately fulfilled its purpose as a Government observatory under the directorship of Maclear, Stone, Gill, Hough and Jones of the present day. This observatory has a reversible transit-circle of the latest type—a heliometer and an equatorially-mounted twin telescope with objectives 24 in. and 18 in. in aperture for photographic and spectroscopic work; gifts of Mr. Frank McClear.

The first observatory on Australian soil was one on Dawes Point, the headland on which stands the present Sydney observatory, established in 1786 at Maskelyne's instigation for the observation of a comet expected to return in 1789. Beyond this little is known of the Dawes Point observatory, but in 1822 Sir Thomas Brisbane, then governor of New South Wales, built and furnished an observatory at Paramatta a few miles to the west of Sydney, where an excellent star-catalogue was made by Carl Runker, and carried on at his expense until the year 1827.

In 1853 Mr. Ellery was appointed to superintend an astronomical observatory at Williamstown which was removed to Melbourne in 1861-63. With the observatories of Sydney and Perth, Melbourne is taking a share in the international work of charting the heavens by photography, and with this meridian observing, magnetism, seismology, meteorology and time-service form its activities. In 1855 Charles Todd was appointed Government astronomer of South Australia, but the Adelaide observatory was not completed until 1861. The observatory of Western Australia at Perth was established 30 years later. The aim of a small observatory established at Wellington, New Zealand, under Sir James Hector in 1869 for time-service has lately been enlarged and the institution is now called the Dominion observatory.

Continental Observatories.—During this period many observatories were established on the continent of Europe, two of which were made famous by the labours of Wilhelm Struve. The University of Dorpat, Livonia, Russia, possessed in 1809 an observatory of small dimensions, scantily equipped, of which Struve, a student of astronomy in the university, was given charge in the year 1813. His successful work attracted the attention of the Russian Government, and soon the observatory was furnished with such instruments and pecuniary means as to raise it to the rank of a first-class establishment, where Struve, almost single-handed, produced results of a very high standard. Attracted by Struve's work the Emperor Nicholas in 1833 resolved to erect a

central observatory for the empire of Russia, and, largely to Struve's design, an observatory was completed in 1839, at Pulkowa near St. Petersburg, which was considered to be the finest and best equipped of the time. It may be described as a collection of buildings forming the home of a number of astronomers. Other observatories of the first half of the 19th century, though not on the magnificent scale of Pulkowa but associated with the names of distinguished astronomers, are those of Königsberg, established by the king of Prussia in 1813 and put in the charge of F. W. Bessel who had already made a reputation at the observatory at Lilienthal. The observatory at Altona near Hamburg, completed in 1823, was made famous because of its association with Schumacher, to whose personality is ascribed the encouragement given to astronomy by the Danish Government. The instruments of this observatory were not of great size for the work of Schumacher lay rather in the direction of geodesy and astronomical literature, and it is to him that astronomy owes the famous publication *Die Astronomische Nachrichten*. Schumacher died in 1850, and his successors, Petersen, Hansen and C. A. F. Peters are also remembered. In 1874, this observatory was transferred to Kiel, which had then become the chief German naval station, and formed the international central bureau for distribution of astronomical information until the World War, when this useful work was transferred to Copenhagen.

The Royal observatory at Berlin had its origin in the year 1705, and for 100 years or more consisted of instruments inadequately housed in the building that was the home of the Academy of Sciences, but was established as a separate building in the years 1832-35, and has accomplished successful work, mainly meridian, though its position in the midst of a populous city is to its detriment. It was with the gin. refractor of this observatory that the planet Neptune was first seen. The establishment of an observatory at the University of Bonn was decided on by the king of Prussia, in 1836, and Argelander, who had been director of the Abo observatory, Finland, transferred to Helsingfors in 1837, was chosen as director. Although the instruments of this observatory are not large, the stupendous work of Argelander, carried on by his successors, in star-cataloguing, indicates its principal branch of activity. The University of Strasbourg has an observatory attached to it completed by the German Government in 1881, consisting of three magnificent buildings placed in a large open garden. Its largest telescope, the great Equatorial, a refractor with object glass of 20 in. aperture, is said to have been the largest in Germany at the time of its erection. The University observatory, Vienna, built on a new site in the years 1874-80 to replace one that dated from the middle of the 18th century, is a large structure standing in grounds of 14 acres in extent, with an imposing façade and surmounted by four domes designed on the model of the Berlin observatory. Basle (1874), Bordeaux (1879), Breslau (1790), Budapest (1856), Cracow (1791), Kazan, Leipzig (1790, remodelled in 1861), Lund, are other universities of Europe that have observatories attached to them. At Heidelberg (Königstuhl), a private observatory founded by Dr. Max Wolf in 1877, was merged in a Grand-Ducal Institute, established in 1898, which combines two sections: one is an astrometric observatory that had existed successively at Schoetzingen, Mannheim and Karlsruhe since 1762 (*v. supra* Mannheim), and an astrophysical observatory under the direction of Dr. Wolf. This observatory has been successful in the discovery of comets and small planets, and in the observation of variable stars, nebulae and the Milky Way. To these may be added the municipal observatory of Hamburg, memorial to Repsold, and the private observatories of Dr. Engelmann at Leipzig, of Baron d'Engelhardt at Dresden, of von Kuffner and von Oppolzer at Vienna.

Before the World War there were ten French national observatories under the control of a consultative committee that reported annually to the Government. The Paris observatory of the 17th century has been mentioned. Some that were resuscitated or created in the ten years after the war of 1870-71, have history behind them. An observatory at Marseilles, founded by the order of Jesuits about the year 1700, was taken over in 1749, after the

2. Royal Observatory, Edinburgh, Scotland
3. Principal astronomical buildings of the U.S. Naval Observatory, Washington, D.C.
4. The Einstein Tower at Potsdam, an astrophysical Observatory used entirely for spectroscopy. The telescope is vertical and occupies practically the entire height of the building
5. Dome of the 24-in. refracting telescope of the Lowell Observatory, Flagstaff, Arizona
6. Sheepshanks Equatorial at the Cambridge Observatory, England. The refracting telescope is furnished with a mirror at the elbow-joint. The observer occupies the upper room
7. Great Equatorial building and dome at the U.S. Naval Observatory, Washington, D.C.

expulsion of the Order, as the Royal Naval observatory and made famous by Pons, Bernard, Gambart, Valz and Chacornac. A new observatory was built in 1862 with which the older one was incorporated and the names of Stephan, Coggia and Borrelly recall many discoveries of minor planets and comets made with its instruments. The observatory at Toulouse had a predecessor as early as 1718, but the existing establishment dates from about 1840 when it was erected and supplied with excellent instruments at the public expense, but with an inadequate staff, so that it was devoted for many years solely to meteors and meteorology. After being closed for three years it was reopened in 1873, the subsequent workers there including Tisserand, Perrotin, Bigourdan and Baillaud, all well-known names in astronomy.

There had nominally been an observatory at Bordeaux for 100 years because the Academy of Sciences of Bordeaux, soon after the transit of Venus of 1769, which had been observed from that city, built a tower 75ft. high, of 20ft. interior diameter that went by that name; but of this the existing observatory, founded in 1879 and completed in 1882, is quite independent. This observatory, together with those at Paris, Toulouse and Algiers, is taking a share in the international work of charting the heavens by photography. The Algiers observatory, about half a century old, is an imposing group of buildings set up on a hill at Boudzareah, near Algiers. The two observatories that complete the ten are the solar physical observatory at Meudon near Versailles, which is actually an old chateau that was converted for the purpose in 1876, and put under the direction of M. Janssen and carried on after his death by M. Deslandres, the present director of the Paris observatory, and the observatory at Nice. This observatory on Mt. Gros was built in 1881 at a cost of five million francs and placed under the direction of M. Perrotin, the principal instrument being an equatorially-mounted refracting telescope of 30in. aperture, which has been employed with considerable success in the observation of comets, asteroids and nebulae. It was bequeathed by the founder to the University of Paris in 1899 and now ranks as a national institution.

American Observatories.—In 1832, Airy closed his report on astronomy to the British Association by remarking that, as for the United States, he did not know of the existence of a single public observatory within the whole country. The first American observatory is said to have been erected at Chapel Hill (N.C.), in 1831-32. It was destroyed by fire in 1838. Projects for observatories were set on foot at Williams college, Mass., in 1836; at Hudson, O., 1836-37; and for the National observatory at Washington which was actually established by Lieut. J. M. Gilliss of the U.S. Navy in 1843-44. The movement was encouraged and in many cases observatories were created by collective financial help. By the efforts of Prof. D. M. Mitchel money was raised for shares

founded as an annex to the university in 1860, and was completed in 1867 through the liberality of Mr. W. Shand. The Dearborn observatory of the University of Chicago was built in 1864 at the expense of a liberal benefactor at a cost of \$30,000, and the instruments were paid for by public subscription. The Halsted observatory, attached to Princeton university, came into existence in 1866 by munificent gifts which paid for site and buildings. At the present time (1928) there are in the United States 70 observatories, some used merely for purposes of education, while others are doing original and brilliant astronomical work.

The U.S. Naval observatory at Washington is something akin to Greenwich, since it is a state-supported institution for the purposes of the Navy. Chronometers and compasses are tested, and the staple astronomical work has been the making of star catalogues. Excluding this, the most famous of these observatories of last century is that of Harvard college, Cambridge, Mass., whose origin is associated with the personality of William Cranch Bond, a member of a Cornish family that emigrated in 1786 and settled in Portland, Me., where he was born in 1789. Bond had great aptitude for scientific research, especially astronomy, and when, in 1837, it was decided to build an observatory for Harvard college, he, though engaged in a profitable manufacturing business, accepted the invitation to take charge. No salary was attached to the office until the year 1846. The original Harvard observatory (Dana House, 1839) and the new observatory (1843-47) were established by public subscription. Under the direction of Prof. E. C. Pickering, the work of this observatory was mainly photometric and spectroscopic. Harvard had no telescope of size, until the new observatory was furnished with a 15in. equatorial telescope, the largest made up to that time, though the observatory at Pulkowa had one of like dimensions. At the present time it has a refracting telescope of 24in. aperture, the gift of Miss Catherine Bruce. It had a branch observatory in Arequipa, Peru, at a high elevation in the Andes, built and largely supported by a sum of money bequeathed for the purpose by Uriah Boyden, but this branch was in 1928 transferred to South Africa. Yale university has an observatory, founded in 1882, which is known for its work on the determination of stellar parallaxes. The private observatory of Percival Lowell at Flagstaff, Arizona, has attracted attention because of the observations of the surfaces of the planets made there, for which it was founded in 1894.

As to South America, there had been an observatory at Buenos Aires in 1822, whose period of activity was short, so that the National observatory at Santiago (Chili) may be regarded as the first permanently founded (1856) on this continent. The National observatory of the Argentine Republic, established at Cordoba in 1870, has done good service in cataloguing the stars of the Southern hemisphere. There are other observatories in South America.

The last quarter of the 19th century may be said to have seen the beginning of the era of the large telescope, though the large specula of Parsonstown and Melbourne (4ft.) were earlier. The 26in. refractor at Washington dates from 1873, but a few years later, a telescope was made on a considerably larger scale through the benevolence of Mr. James Lick, who died in San Francisco on Oct. 1, 1876. On Jan. 9, 1887, Mr. Lick's body, transferred from its original place of burial, was deposited in the foundation pier of a great equatorial telescope, with object glass 36in. in diameter, that had been set up in a fine observatory on Mt. Hamilton, Calif., at a total cost of \$610,000, including \$50,000 invested as endowment. In 1895 a reflector with a silver-on-glass mirror of 36in. diameter, that had been used by Dr. Common, was presented by Mr. Crossley of Halifax, England, and with these two instruments and others, the Lick observatory, dedicated to the University of California, has done much photographic and spectroscopic observation. The size of the larger instrument was surpassed ten years later when at the instigation of Mr. George E. Hale, Mr. C. T. Yerkes presented a refracting telescope with object glass of 40in. aperture, together with a large observatory building containing it on the shore of Williams bay, Lake Geneva, Wis., to the University of Chicago in Oct. 1897. From that date the Yerkes observatory has been a centre of astronomical activity. The programme has been, to a great extent, spectroscopic and

in a public company to build an observatory at Cincinnati. The first meeting of stockholders was held on May 23, 1842, and an object glass 11in. in diameter, which was quite large for that epoch, was procured during the summer. The Litchfield observatory of Hamilton college, New York, was founded by public subscription in 1852. An observatory attached to the University of Missouri in 1853 was afterwards improved by a gift from Dr. S. S. Laws. In 1856, the Dudley observatory, Albany, was established by gifts from citizens of that city, and took its name from the largest donor, Mrs. Blandina Dudley. The Allegheny observatory was

astrophysical but micrometrical work on double stars, planets and satellites, has had a place, together with work in connection with the discovery and observation of comets.

TWENTIETH CENTURY

Modern Observatories.—The names and locations of nearly 300 active observatories will be found in the *Nautical Almanac* for 1930. The progress of astronomy and the changes in the aim of celestial research have brought changes in the characteristics of observatories. At the beginning of the 19th century the equipment of a public observatory may be said to have consisted of a meridian instrument with an equatorial as subsidiary; today the latter is generally the more important instrument, and often is supplemented by plate measuring apparatus.

The routine determination of the positions of sun, moon, the planets and stars still continues as staple work at Greenwich, Washington and other national observatories, for such records are necessary for the maintenance of fundamental astronomy. But the Government and university observatories have now added equatorial instruments, generally large, and frequently adapted for photography, to their equipment and pursue in addition some branch of astrophysical work.

Outstanding facts of the 20th century have been the making of large telescopes, in some cases of novel design for special researches, and the establishment of branches to existing observatories in places considered more suitable meteorologically than those of their parents. The earliest example is the solar observatory set up on Mt. Wilson, 5,700ft. above sea-level, near Pasadena, California, in 1904-05 as an offshoot of the Yerkes observatory. This observatory is now at the charge of the Carnegie Institution of Washington. In 1918 the word "solar" was dropped since the physical qualities of stars other than the sun are there studied. The instruments are on the mountain for observing. The library, laboratory and administrative offices of the observatory are in the valley below. A new type of telescope has been evolved for solar observation—the tower telescope. A revolving mirror known as a coelostat, and a fixed mirror on the top of a tower reflect the sun's light through an object-glass downwards, to form an image of the sun on the slit of a spectroscope in a pit below. The light then passes through the spectroscope to record itself on the photographic plate, or to be otherwise examined, the scheme obviating the difficulty of carrying long instruments on a moving frame. This observatory has a tower telescope 150ft. high and also a reflecting telescope with a mirror 100in. in diameter, the largest yet in use (See Plate), carried in the usual manner on an equatorial mounting, and with this is used an Interferometer for measuring the size of the stars. Another large telescope is the 72in. reflector (see Plate) at the Dominion of Canada Astrophysical observatory established in 1916 at Victoria, B.C., as a branch of the Dominion observatory at Ottawa, that itself had grown from a modest establishment used by the Survey department. In the eastern hemisphere an observatory specially adapted for solar investigation was established at Canberra by the Federal Government of Australia as a link in the chain of such institutions round the world, of which the Solar Physics observatory at Cambridge (England) (removed from South Kensington in 1911) and that at Kodaikanal, southern India (which was established as a Government institution about 1900 and replaces, in part, the observatory of the Government of Madras founded in 1792), are others. A site has been chosen in south-west Africa under the auspices of the Smithsonian institution of Washington for a station for the special study of solar radiation. The Harvard southern station has been transferred from Arequipa in Peru to Mazelspoort, 14m. from Bloemfontein, Yale university observatory has set up a southern branch at Johannesburg; and the Ann Arbor observatory of Michigan has lately done the same at Bloemfontein by the help of a generous donor, the principal instrument being a refractor of 27in. aperture, that is to be used largely for observing double stars. In the same connection it may be noted that the observatory of the Union of South Africa at Johannesburg which dates under its present name from 1912 (having previously been known as the Transvaal observatory, when it was

mainly a meteorological station) has lately procured a 26in. refracting telescope, so that, including the Royal observatory at Capetown, there are now five observatories with large instruments in this part of the globe as well as several belonging to amateurs who work on special lines. On the other hand the observatory at Durban, in charge of the colonial Government of Natal, was closed in 1912.

Some notable additions have been made to the observatories of Europe in the quarter of a century just passed. As the climate of Pulkowa was considered to be unfavourable for observation, through the influence of Oscar Backlund, who was its director for 21 years, branch establishments were founded—one at Odessa in 1898 for the astronomy of position; another at Nicolaieff, 75m. from Odessa, in 1912, for a similar purpose; and a third at Simeis in the Crimea. Backlund died in 1916, but in the last few years of his life the Russian Government sanctioned the expenditure of large sums of money for the purpose of procuring astrophysical and astrophotographic equipment for the new observatories, and recently (1926) a reflecting telescope with a mirror one metre in diameter and a photographic refractor with an objective of 41in. aperture have been supplied to the Simeis observatory by a British firm. The observatory of Geneva, which is of very early foundation (1772), now possesses a reflector with mirror, one metre in diameter, the gift of a member of the staff. The Astrophysical observatory at Potsdam, that dates from the year 1878, was enriched by the addition of a 32in. photographic refractor in the year 1890, and in 1921 a tower-telescope was erected in its grounds as a tribute to Prof. Einstein. The building is modern and original (see Plate). The primary purpose of the apparatus is to test the Einstein theory, so far as it refers to the shift of spectral lines, but it will be available for other astrophysical work.

A tower-telescope has been set up at the Royal Astrophysical observatory at Arcetri (Florence) designed for solar observation. A new object-glass was supplied to this institution in 1925 by the German Government, by way of war reparation. The Italian Royal Observatory at Milan, with which the name of Schiaparelli is associated, has been removed and improved by the help of resources similarly supplied. Another observatory that has been largely developed in this century is that of the City of Hamburg, at Bergedorf. Citizens supplied funds for buying instruments for the local school of navigation which already had a small equipment, and so the Hamburg municipal observatory developed and had a long and honourable career. In 1906 it was decided to transfer it to Bergedorf, about 5m. south of Hamburg, and the new establishment was completed in the course of the year 1909. This observatory continues to do star-cataloguing work and supplies a time service for the city, but it is well equipped for astronomical observations of other kinds. It has a reflector, one metre in aperture, and a large twin telescope for photography. This observatory has been specially successful lately in the discovery of comets.

In Great Britain, the Norman Lockyer observatory, originally the Hill observatory, is on the top of Salcombe Hill near Sidmouth, Devon. This observatory, at a height of 560ft., contains instruments from the observatory of the late Dr. Frank McClean at Rusthall, near Tunbridge Wells, and others used at the Government establishment formerly at South Kensington. The spectroscopic classification of stars and the determination of their parallaxes from examination of their spectra, are items in its programme.

Mention has not been made of all the observatories of past and present importance. Other countries of Europe besides those named have observatories in active work. The Society of Jesus has establishments in various parts of the world devoted to seismology, meteorology, and in some cases to astronomy. The Nizamiah observatory, Hyderabad, which is taking a share in the International Astrophysical Catalogue is a striking instance of an observatory devoted to a special line of work.

OBSERVER CORPS IN AIR DEFENCE. At the beginning of the World War the requirements of air defence had hardly been considered, but very soon the importance of knowing the movements of the hostile aircraft became evident. The information was required both for purposes of active defence, and also for the system of air raid warnings. At first, in Great Britain the defences were in the hands of the Admiralty, who arranged with the police to telephone reports of any aircraft heard or seen within 60 miles of London. Early in 1915 this system was extended to include East Anglia, Northampton, Oxfordshire, Hampshire and the Isle of Wight; and in April, 1915, chief constables were asked to telegraph similar messages to the War Office; there was much overlapping. The system was then extended to cover England and Wales, the reports to come to the Admiralty, who would inform the War Office. Direct interchange of intelligence was also arranged between the chief constables. In 1916 the War Office took over, and a more regular system of observers was introduced, cordons were organized 30 miles outside vulnerable areas, London was provided with two cordons, and coastal posts were organized.

Later Intelligence Arrangements.—The above system was in force when the London air defences were re-organized under General Ashmore in the autumn of 1917. The aeroplane patrol work was improving at the end of 1917, but information from the cordons, etc., was not quick or certain enough for the use of the pilots. Early in 1918 therefore a new system was inaugurated; the German activity was then confined to London and the south and east of it, and this area was well covered with the various units of the defence, coastal posts, squadrons, guns, searchlights and balloon aprons. A system of reporting from all these units was arranged by which their information came through certain centres, and so on to a big map in the headquarters. During operations the lines were always through, and no ringing up was required. The necessary telephone construction work was heavy, and the system was not ready until after May 19, 1918, the occasion of the last raid.

Beginnings of the Observer Corps.—On the revival of air defence in the beginning of 1924, it was plain that unless special measures were taken, large areas would be blank so far as any aircraft intelligence was concerned. The requirements were simple; no hostile aircraft must be allowed to move over any part of the country without its movements being known constantly and instantly at the headquarters of the air defences. To obtain the information it was necessary to cover the country, within range of bombing, with a series of posts, six to eight miles apart, provided with suitable watchers and a complete telephone organization for quick reporting. The first experiment was made in 1924. A few posts were organized at the required interval round Cranbrook, which was the reporting centre. The experiment went to show that the scheme was feasible, and valuable experience was gained.

Organization and Working.—In 1925 the system was extended to two zones covering the whole of Kent and Sussex; each zone consisting of a network of observer posts connected by direct telephones to an observation centre, the centres again being connected up to the headquarters of the air defences. The posts and centres were manned by special constables, enrolled for this object by the chief constables of counties and boroughs. The 1925 lay-out was well tested by day and night work with the R.A.F. After the 1925 work, the organization received the official sanction of the Home Office and the War Office, and the general terms of service for the special constables were fixed. In 1926, two further zones were organized, so that by 1927 the system was in working order from the west of Hampshire, through Hampshire, Sussex, part of Surrey, Kent, Essex and half Suffolk. The administration under the chief constables and regular police works smoothly. The observers, who do the work without pay, are keen and efficient. Each group of about 25 posts communicates direct to a centre.

In the centre is a large table map on to which the observer lines

are laid. Plotters sit round the table with telephone headsets on, three posts to each plotter. As the reports come in, they are plotted on the control map, and an independent recorder keeps a record. A teller overlooks the control map, and reports to the air defence headquarters the courses as they appear. Periodical exercises are held in which large numbers of bombing and fighting aeroplanes fly over the posts. The system transmits the courses with certainty and with great rapidity, and has proved itself an indispensable part of the air defence organization. (E. B. A.)

OBSIDIAN, a glassy volcanic rock of acid composition. Rhyolitic lavas frequently are vitreous, and when the glassy matter greatly predominates and the crystals are few and inconspicuous the rock becomes an obsidian; the chemical composition is essentially the same as that of granite; the difference in the physical condition of the two rocks is due to the fact that one consolidated at the surface, rapidly and under low pressures, while the other cooled slowly at great depths and under such pressures that the escape of the steam and other gases it contained was greatly impeded. Few obsidians are entirely vitreous; usually they have small crystals of felspar, quartz or a ferromagnesian mineral, and when these are numerous the rock is called a porphyritic obsidian. These crystals have, as a rule, good crystalline form, but the quartz and felspar are often filled with enclosures of glass.

All obsidians have a low specific gravity (about 2.4) both because they are acid rocks and because they are non-crystalline. Their lustre is vitreous except when they contain many minute crystals; they are then velvety or even resinous in appearance. Black, grey, yellow and brown are the prevalent colours of these rocks. In hand specimens they often show a well-marked banding which is sometimes flat and parallel, but may be sinuous and occasionally is very irregular, resembling the pattern of damascened steel. When crystals are present they generally have their long axes parallel to the fluxion.

Even when conspicuous and well formed crystals are not visible in the rock there is nearly always an abundance of minute imperfect crystallizations (microlites, etc.). They are often so small that high magnifications may be necessary to ascertain their presence. Some are globular and others are rod-shaped; they may be grouped in clusters, stars, rosettes, rows, chains or swarms of indefinite shape. In banded obsidians these microlites may be numerous in some parts but few or absent in others. The larger ones polarize light, have angular outlines like those of crystals, and may even show twinning and definite optical properties by which they can be identified as belonging to felspar, augite or some other rock-forming mineral.

These microlites or crystallites (*q.v.*) show that the glassy rock has a tendency to crystallize which is inhibited only by the very viscous state of the glass and the rapidity with which it was cooled. Another type of incipient crystallization which is excessively common in obsidian is spherulites (*q.v.*), or small rounded bodies which have a radiating fibrous structure. They are of globular shape, less frequently irregular or branching, and may be elongated and cylindrical (axiolites). In some obsidians from Tenerife and Lipari the whole rock consists of them, so closely packed together that they assume polygonal shapes like the cells of a honey-comb. In polarized light they show a weak grey colour with a black cross, the arms of which are parallel to the cross-wires in the eyepiece of the microscope and remain stationary when the section is rotated. Often bands of spherulites alternate with bands of pure glass, a fact which seems to indicate that the growth of these bodies took place before the rock ceased to flow.

As cooling progresses the glassy rock contracts and strain phenomena appear in consequence. Porphyritic crystals often contract less than the surrounding glass, which accordingly becomes strained, and in polarized light may show a weak double refraction in a limited area surrounding the crystal. Minute cracks are sometimes produced by the contraction; they are often more or less straight, but in other cases a very perfect system of rounded fissures arises. These surround little spherules of glass which are detached when the rock is struck with a hammer. There may be concentric series of cracks one within another. The minute globular bodies have occasionally a sub-pearly lustre, and glassy rocks

which possess this structure have been called *perlites* (*q.v.*).

Although rocks wholly or in large part vitreous are known from very ancient geological systems, such as the Devonian, they are certainly most frequent in recent volcanic countries. Yet among the older rocks there are many which, though finely crystalline, have the chemical composition of modern obsidians and possess structures, such as the perlitic and spherulitic, which are very characteristic of vitreous rocks. By many lines of evidence we are led to believe that obsidians in course of time suffer devitrification, in other words they pass from the vitreous into a crystalline state, but as the changes take place in a solid mass they require a very long time for their achievement, and the crystals produced are only of extremely small size. A dull stony-looking rock results, the vitreous lustre having entirely disappeared, and in microscopic section this exhibits a cryptocrystalline structure, being made up of exceedingly minute grains principally of quartz and felspar. Often this felsitic devitrified glass is so fine-grained that its constituents cannot be directly determined even with the aid of the microscope, but chemical analysis leaves little doubt as to the real nature of the minerals which have been formed. Many vitreous rocks show alteration of this type in certain parts where either the glass has been of unstable nature or where agencies of change such as percolating water have had easiest access (as along joints, perlitic cracks and the margins of dikes and sills). Obsidians from Lipari often have felsitic bands alternating with others which are purely glassy. In Arran there are pitchstone dikes, some of which are very completely vitreous, while others are changed to spherulitic felsites more or less silicified.

Obsidians occur in many parts of the world along with rhyolites and pumice. In Europe the best-known localities for them are the Lipari Islands, Pantellaria, Iceland and Hungary. Very fine obsidians are also obtained in Mexico, at the Yellowstone Park, in New Zealand, Ascension and in the Caucasus. Included in this group are some rocks which are more properly to be regarded as vitreous forms of trachyte than as glassy rhyolites (Iceland), but except by chemical analyses they cannot be separated. It is certain, however, that most obsidians are very acid or rhyolitic. The dark, semi-opaque glassy forms of the basic igneous rocks are known as tachylytes. The typical obsidians exhibit the chemical peculiarities of the acid igneous rocks (*viz.*, high percentage of silica, low iron, lime and magnesia, and a considerable amount of potash and soda) as shown in the following table.

	I. Yellowstone Park	II. Iceland	III. Mexico
SiO_2	74.70	75.28	73.63

(J. S. F.)

OBSTETRICS (MIDWIFERY). Obstetrics, together with Gynaecology (*q.v.*) and Paediatrics cover the greater part of the reproductive cycle (*i.e.*, from the parents of one generation to those of the next), the portion falling strictly within the sphere of Obstetrics being from conception through pregnancy, labour and lying-in up to the time of the return of the mother to her ordinary duties. The start may be made even before conception for the obstetrician may be called on to advise as to the marriageability of a woman, *i.e.*, of her capacity to be a wife and mother, because of some disease or deformity of the genital organs or bony pelvis, or general disease, as of the heart, lungs or elsewhere, on which his experience of the effects in pregnancy and labour will be required. Midwifery is associated in the minds of the public with attendance at a confinement, and the woman who engages a doctor thinks of his duties as seeing her safely through the crisis of childbirth and relieving her, so far as the resources of

medicine will allow, of the pains associated therewith.

Labour.—Labour comes on about 280 days after the first day of the last menstrual period and is divided into three stages. The first and longest is occupied by the opening up of the mouth of the womb; the second stage, lasting usually two hours or less, represents the time from full dilatation to the expulsion of the child; the third stage, half an hour or less, covers the period of the expulsion of the afterbirth. The motive power in all stages of labour is the contractions of the strong muscular wall of the womb, aided in the last two stages by the bearing down efforts of the abdominal muscles. The "pains of labour" are caused by the powerful colic-like contractions of the womb with, towards the end, the stretching of the passages as the child is being born.

The first stage may last even to days without harm to mother or child so long as the waters are unbroken, as the water-bag is an efficient protection to both, but danger to the child especially may result in those cases of premature breaking of the waters in which the presenting part does not come down and block the escape of all the water. The "dry" labour in which the water is lost is always a difficult one.

To be normal the head of the child, and the top of the head (vertex) should come first, that is, present, and does so in over 95 per cent. of cases and its position should be such that the hind part of the head is born before the forehead. The labour is often longer and more difficult when the back of the child is backwards in the womb.

The chief difficulties arise from other presentations than those of the top of the head,—sometimes the face presents (once in 300 cases) and may cause a long and difficult labour, and more rarely the brow (1 in 1,200), a still more difficult presentation, as the passage of a full-time child is not possible until the presentation is altered to a face or a vertex. The most frequent abnormal presentation is a breech, when the buttocks come first and the head last, as it occurs about 1 in 40 cases. It, however, is not more serious to the mother than a vertex presentation, but the child is more likely to be still-born, being suffocated owing to the head coming last. Another, and happily rare, malpresentation is the cross-birth (1 in 250) in which the child lies across the passage, as if not changed, it completely obstructs the birth. Twins occur about once in 80 births, and add slightly to the risks, because the children are often small and the labour premature and slow with the first child. The second child is usually born easily because the passages are already dilated. A single unduly large child is much more likely to give rise to difficulty; it is always unfortunate if the child weighs over 10 lb.—the more desirable weight is one of 6 to 7 lb.

Complications.—Among the more serious complications are those giving rise to (1) haemorrhage during birth (commonly due to misplacement of the after-birth which is in front of the child and to early separation of the placenta), (2) convulsions (eclampsia), occurring usually in women with kidney disease and (3) labour obstructed by deformity of the pelvic bones narrowing the bony canal through which the child must pass or by tumours blocking the canal. In the marked degrees of pelvic deformity the only chance of obtaining a living child is by Caesarean Section (*q.v.*). Delivery by the natural passages in such cases may be possible only by destroying the child and the risk of injury to, and death of, the mother in these destructive operations may be as great as the Caesarean operation.

Much the most common cause of failure of the woman to deliver herself is due to relative or absolute weakness of the uterine contractions (pains). Relative, if in a first confinement the soft passages, and especially the outlet, are rigid, or in any confinement in which owing to the size of the child or its position or the narrowness of the passages, some extra effort on the part of the womb is required and is not forthcoming. Absolute weakness is present in those cases in which no additional effort is called for and yet there is insufficient power to expel the child without great prolongation of labour.

Feeble action of the womb may be due to loss of the stimulus of the dilating bag by early breaking of the waters; if the presenting part comes down to take the place of the bag, all will go well,

but if it does not there is nothing to prevent all the waters dribbling away and a dry labour of this kind is always difficult, and the child may be stillborn. A loaded bowel or a full bladder also interferes with uterine action and these viscera must be kept empty. Fatigue is a very important factor in this regard for the womb of the tired out woman will not function efficiently. Anxiety, lack of confidence in her own powers and long continued pain act in the same way and hasten the production of fatigue. The relief of pain, the obtaining of rest and general management of the patient is, therefore, a most important part of the medical attendant's duties. The problem is not an easy one because sedatives, anaesthetics and means of relieving pain also tend to lessen, at any rate, for a time, the muscular activity of the uterus.

Lying-in Period.—During the lying-in period, rest and quiet are essential, particularly for highly-strung women, but rest to mind more than to body. The patient should sit up in bed and move about so as to promote free escape of the discharges. She is not an ill woman and is kept in bed to allow time for healing and the return of the enlarged and relaxed structures to their pre-pregnancy state. It is useless to say how long the woman should remain in bed or in her room; every case must be decided as an individual problem;—a longer stay being required by those who have had complications, who are worn out and require rest, sleep badly or are of a nervous and over-anxious temperament; a shorter by those in whose cases everything has been straightforward, who sleep well and are of an easy-going nature and do not worry. Much can be done in the way of massage and bed exercises and after rising by Swedish exercises to restore the abdominal and pelvic muscles,—a most important measure in preserving the figure and lessening the chances of dropping of the abdominal viscera and womb. The chief danger during the lying-in period is that of puerperal fever (*q.v.*) and its sequelae.

Preventive Obstetrics.—In the last 20 years a striking change has occurred in the science of obstetrics and its practice, chiefly as the result of its invigoration by the spirit of preventive medicine.

The term "preventive medicine" (*q.v.*) does not connote any special creed or peculiar doctrine in medicine. Its first object is to seek out the causes of disordered function and remove them before they can become operative and, in the second place, when these causes are unknown, to detect the early signs of deviation from normality and restore the normal before trouble arises. The maintenance of natural function in all bodily systems is its aim.

If obstetrics is regarded from this point of view the difference between the new and the old practice will become obvious. Its immediate purpose will be to secure normal reproduction by detecting and removing all known causes of disorder of function and by observing the healthy pregnant woman from conception onwards to discover any sign of departure from the normal. Though a physiological state, pregnancy imposes a strain on the efficient working of every system of the body, and the thorough examination of the state of health of mind and body of the woman early in her pregnancy and further observation to see how she is standing the test seem but reasonable precautions. Apart from those who have some organic weakness and may break down under the strain, there are disorders of function that may develop in those previously of sound physique. A special strain falls on the excretory organs, and the kidneys and the liver may be affected and lead to acute or chronic disease. Hence the need for the routine and repeated examination of the urine. The good health of the mother throughout childbearing increases her resistance to infection (*e.g.*, puerperal fever) and her efficiency in the rearing of her family.

The care of the pregnancy itself is likewise a matter of greater concern than in the older obstetrics, not only because of the loss of prospective life, but because miscarriage is a prolific cause of operative interference, during or after its occurrence, and of infective and other diseased conditions of the reproductive tract and thus of subsequent disability. Premature labour results in the birth of weakly infants difficult to rear and is a prominent factor in the persistent high mortality among new-born infants. Another important object of the supervision of the pregnant

woman, that of foreseeing and avoiding difficulties and complications during labour, provides the simplest illustration of the changed outlook in obstetrics.

The usual custom of a generation ago was for the woman to retain her doctor for attendance on her confinement and for the doctor to do little more than note the expected date on which his services might be required. Unless consulted by the patient because of some disturbance of health, he might not see her again until summoned at the onset of labour. He then made a thorough investigation to see if all was straightforward or if there was any malpresentation or other difficulty, and was prepared to do his best to remedy any untoward condition that might be present or arise later, often being exceedingly ingenious and resourceful in so doing. His obstetric training as a student had been directed largely toward teaching him the management of normal labour, the emergency treatment of abnormal presentations and obstructions to the passage of the foetus through the birth canal and other complications during labour, and his reputation as an accoucheur was largely determined by his capacity to cope with emergencies.

Modern Methods.—The training of the modern student is conducted on other lines, and whenever a complication occurs the first question discussed is, "Could this have been foreseen?" and if so, the next question is, "What should then have been done?" and a comparison of the case as he has seen it with what it might have been had the emergency been anticipated is used to impress on him that the sole criterion of sound obstetrics is the securing of natural parturition and the prevention of unexpected difficulties and complications so far as the present state of our knowledge allows.

To avoid difficulties in labour, examination is begun about six weeks before the expected date of confinement in order to determine that the child is presenting normally and that there is sufficient accommodation in the bony pelvic canal to allow of its easy passage. This examination is repeated two or three times to make sure that no change has occurred in the presentation and position and that the child does not become unduly large to pass readily. For the most part these matters can be determined with a fair degree of accuracy by the ordinary methods of obstetric examination, but in difficult and special cases examination under anaesthesia and by X-rays may be required. Should it be discovered that even at six weeks before full time there will be difficulty in the child being born by the natural passages, because of rickety or other deformity of the pelvic bones, the question arises whether it is better to resign all hope of the delivery of a living child by the natural passages and perform Caesarean section or to induce labour and learn if the natural powers can effect the delivery of a small and premature infant.

If there does not appear to be any obstruction at the time of the first examination but at a later one there is evidence of a tight fit, labour should be brought on then to avoid the risk of the child becoming too large to be born without difficulty. By eliminating difficulties due to disproportion in size between the child and the mother's pelvic canal and such malpresentations as those previously mentioned most of the serious difficulties in labour can be obviated in some way or other. The change in presentation and position of the child can be effected by manipulation through the abdomen, if done before the child is too large to be moved readily, and in favourable cases and under anaesthesia sometimes even up to and after the onset of labour, but if left until the waters have broken or labour is advanced, requires internal operative procedures with their additional risks of injury and infection.

In these instances the cause of difficulty can be anticipated and removed before labour begins, but there are also many conditions of which the cause is unknown so that the obstetrician must fall back on the second line of defence, that of discovering the earliest signs of disturbance, taking them as a warning of danger ahead and making the best possible dispositions. Premature detachment of the after-birth commonly shows itself by haemorrhage and all pregnant women whilst under supervision are warned to report at once any bleeding, so that immediate measures may be taken to

lessen the chances of serious consequences. Albuminuria, discovered by frequent examination of the urine, convulsions (eclampsia), excessive vomiting and visual disturbances are warnings of dropsy.

Pre-maternity supervision is in its infancy, but with experience of its working much more will be possible in the way of prevention. Many of its problems have scarcely begun to be worked out and an example of one of the most outstanding of them is worth a little consideration as an example of the problems that obstetrics has to face.

A Widened Outlook.—When these wider questions are looked into, there is little ground for complacency among those responsible for the obstetric practice of the country. There has been no reduction in maternal mortality equivalent to the drop in the general death-rate or to the remarkable fall in the infantile mortality, which has been halved since the beginning of this century. Further analysis of the registrar-general's figures in England and Wales shows that septicaemia, a form of blood-poisoning practically eliminated from general surgery by the antiseptic and aseptic technique, is still too prevalent and still causes (as puerperal sepsis) about a third of the deaths in childbearing. The annual rate of maternal deaths per 1,000 live births registered in England and Wales is a little under four. In the bad years immediately after the War, the rate was over four per 1,000. In the United States (1920) the rate was 7.99 per thousand. This may not appear large but means that about 3,000 women in the prime of life die in childbearing with the loss of their maternal care to many more young children, and of these mothers over 1,000 die from puerperal sepsis, a preventable disease. Its prevention is a more complicated matter than, and a somewhat different problem from, that of surgical sepsis, because septic organisms may be present in the lower genital tract and spread upwards and into the blood stream, apart from any question of failure of aseptic technique on the part of the attendant.

The statistics of all maternity hospitals show that fever in childbed increases with all complications and difficulties calling for internal manipulation, all of which tend to the introduction or upward spread of infective organisms. The more prolonged and the higher up the tract the manipulation, the greater is the incidence of fever. By far the commonest operative interference is delivery by the forceps because it is advocated by many merely in order to shorten the patient's suffering. Instead of trying to secure natural delivery in cases of weak uterine action, a substitute for the uterine power is adopted in the shape of the muscular power of the attendant exerted through the obstetric forceps. The causes of weak uterine power are difficult to determine and often impossible to foresee, but here is a direction in which investigation is necessary.

Particularly calling for solution are the questions, how far modern social conditions have lessened the power of the woman of to-day to stand the hardship, fatigue and mental and physical strain of child-birth and rendered her less capable of completing the expulsion of the child naturally than the mothers in the days before anaesthesia and frequent forceps delivery; what are the factors tending to produce this lessened capacity; and, how far are they removable?

The obstetrical centre of gravity has thus been shifted backwards from the care of labour to the supervision of pregnancy and a wider outlook over the reproductive cycle is taken so that the part played by obstetrics is seen as but part of the wider subject that is concerned with securing the health of the new generation at the minimum of cost to the old. The pre-maternity supervision looks forward to the nursing of the child and the rearing of the family. It anticipates the natural feeding of the infant by removing all causes that may interfere with breast feeding. It has an educational side and endeavours to inculcate sound principles of hygiene in the preparation for, and the care of, the babe when born, because success in this direction will mean a better start for the new generation. The observation of the developing child falls to paediatrics and the two subjects, as maternity and child welfare, have become a duty and charge to local health authorities, and as such are well known to the public.

In conclusion a tribute should be paid to the late Dr. Bantyne of Edinburgh, as the advocate of pre-maternity supervision and the pioneer of the antenatal clinic, which more than anything else has served to further the permeation of obstetrics by the spirit of preventive medicine. See J. S. Fairbairn, *Gynaecology with Obstetrics* (1926). (J. S. FA.)

OCALA, a city in the interior of Florida, U.S.A., 100 m. S.W. of Jacksonville; the county seat of Marion county. It is on Federal highway 41; has a municipal airport; and is served by the Atlantic Coast Line and the Seaboard Air Line railways. Pop. 6,721 in 1925 (State census), of whom 2,681 were negroes; estimated locally at 8,500 in 1928. The city has extensive lime quarries, phosphate mines, turpentine distilleries and hardwood factories, and is a shipping point for fruits and vegetables. Five miles east is Silver spring (so called from the remarkable transparency and refractive powers of its waters) which has a circular basin 300 ft. in diameter and 65 ft. deep, and discharges over 300,000 gal. a minute, its outflow forming a navigable stream 9 m. long, emptying into the Oklawaha river. Ocala was settled in 1845 and chartered as a city in 1848. It has a council-manager form of government. The name is Seminole, meaning green land.

OCAÑA, a town of central Spain, in the province of Toledo; on the extreme north of the tableland known as the Mesa de Ocaña, with a station on the railway from Aranjuez to Cuenca. Pop. (1920) 6,196. Ocaña is the Vicus Cuminarius of the Romans, and was the dowry that El Motamid of Seville gave his daughter Zaida on her marriage with Alphonso VI. of Castile (1072-1109).

BY COURTESY OF CARL FISCHER, INC., N.Y.
THE OCARINA, A WIND INSTRUMENT POPULAR AMONG STREET PLAYERS

OCARINA, a wind instrument invented in Italy, which must be classed with musical toys or freaks. It consists of an earthenware vessel in the shape of an egg with a pointed base and perforated with holes and a tube like a spout in the side, which contains the mouthpiece. In America, it is sometimes called a "sweet potato."

O'CAROLAN (or CAROLAN), TURLOGH (1670-1738), Irish bard, son of John O'Carolan, a farmer, was born at Newtown, near Nobber, Co. Meath. At eighteen he became blind from smallpox. He received special instruction in music, and used to wander with his harp round the houses of the surrounding gentry, mainly in Connaught. The number of Carolan's musical pieces, to nearly all of which he composed verses, is said to exceed two hundred. He died on March 25, 1738, and was buried at Kiltonan.

His poetical *Remains* in the original Irish, with English metrical translations by Thomas Furlong, were printed in Hardiman's *Irish Minstrelsy* (1831). Many of his songs were preserved among the Irish MSS. in the British Museum.

OCCAM, WILLIAM OF (c. 1300-1349), English schoolman, known as *Doctor invincibilis* and *Venerabilis inceptor*, was born at Ockham, Surrey, and after joining the Franciscans, studied from 1312 to 1318 at Merton college, Oxford, where he taught until 1324, when he was summoned to Avignon to account for some of his doctrines. While he was confined to his convent, in 1326, John XXII. ordered various theses from his works to be examined by the masters of theology, but his works were not actually condemned. Two years later his championship of the Spirituals brought him into a further conflict with the pope, and as a result, he and Michael of Cesena, general of the order, joined the emperor Louis of Bavaria who was at that time in contest with the papal curia. It was for Occam's share in this controversy that he was best known in his lifetime. Michael of Cesena died in 1342, and Occam, who had received from him the official seal of the order, was recognized as general by his party. He probably died at Munich in 1349, having tried to be reconciled with the Church after the death of the emperor.

Occam was one of the most interesting figures in the great contest between pope and emperor, which laid the foundation of modern theories of government, in the disintegration of scholasti-

cism and in the rise of theological scepticism. In the *Opus nonaginta dierum* (1330) (written in reply to John XXII's libellus against Michael of Cesena), and in its successors, the *Tractatus de dogmatibus Johannis XXII. papae* (1333-34), the *Compendium errorum Johannis XXII. papae* (1335-38) and in the *Defensorium contra errores Johannis XXII. papae* (1335-39), Occam only incidentally expounds his views as a publicist, the *Compendium* being of special interest because it selects four papal constitutions which involved a declaration against evangelical poverty, and insists that they are full of heresy. The *Super potestate summi pontificis octo quaestionum decisiones* (1339-42) attacks the temporal supremacy of the pope, insists on the independence of kingly authority, which he maintains is as much an ordinance of God as is spiritual rule, and discusses what is meant by the State. His views on the independence of civil rule were even more decidedly expressed in the *Tractatus de jurisdictione imperatoris in causis matrimonialibus*, in which he contends that it belongs to the civil power to decide cases of affinity and to state the prohibited degrees. By 1343 his great work the *Dialogus* (see Goldast ii. 398-957), in which he attempted to summarize his views, was in circulation. His last work, *De Electione Caroli IV.*, restates his opinions upon temporal authority.

In philosophy, Occam's most significant doctrines fall within the departments of psychology, metaphysics and theology. In the first, he contends that since singulars alone exist, the universal, which is a kind of mental label, has an objective value only inasmuch as it is thought; that the *intellectus agens* and the *species intelligibiles* are superfluous because abstraction follows naturally upon perceptions or intuition, the fundamental form of human knowledge; that will and not intellect is the primary faculty of the soul, and that both faculties, like memory, are identical with the substance of the soul; and that a *forma corporeitatis* must be admitted if the independence of the soul is to be preserved. In metaphysics, Occam teaches that matter has its own essence apart from form; that accidents are only aspects of substance; that the problem of individuation is meaningless because each thing is singular in itself, and that between essence and existence there is no real distinction. The famous dictum—*Essentia non sunt multiplicanda praeter necessitatem*—has become known as "Occam's Razor," but it was already stressed by Duns Scotus. In theology, Occam's scepticism is especially noticeable in his assertion that the existence of God and His attributes, including His unity and infinity, are not strictly provable. According to Occam, the most characteristic activity of God is willing, and moral laws are good only because God wills them and not in their own right.

BIBLIOGRAPHY.—Occam's political works were edited by Goldast (Frankfurt, 1614) and further mss. by R. Scholz (Rome, 1914). The *Dialogus* appeared separately in 1495, the *Defensorium contra Joannem XXII.* in 1513, and the *De Imperatorum et pontificum potestate* in 1927 (edit. C. K. Brampton). Of the non-political works, the *Commentary on the Sentences* appeared in 1483 and 1495, the *Quodlibet* in 1487 and 1491 and the logical treatises fairly frequently in the 15th and 16th centuries.

Full bibliography in Überweg, *Gesch. der Philosophie* (ed. 2, 1928).

OCCASIONALISM, in philosophy, a term applied to that theory of the relation between matter and mind which postulates the intervention of God to bring about in the one a change which corresponds to a similar change in the other. The theory thus denies any direct interaction between matter and mind. It was expounded by Geulincx and Malebranche to avoid Descartes's dualism of thought and extension, and to explain causation.

OCCLEVE (or HOCLEVE), **THOMAS** (1368-1450?), English poet, was born probably in 1368/9. What is known of Occleve's life has to be gathered mainly from his works. At eighteen

or nineteen he obtained a clerkship in the Privy Seal Office, which he retained on and off, in spite of much grumbling, for about thirty-five years. In 1399 he received a small annuity, which was not always paid as regularly as he would have wished. "The Letter to Cupid," his first poem to which we can affix a date, was translated from *L'Épître au Dieu d'Amours* of Christine de Pisan in 1402, evidently as a sort of antidote to the moral of *Troilus and Cressida*, to some mss. of which we find it attached. About 1410 he settled down to married life, and the composition of moral and religious poems. His longest work, *The Regement of Princes* or *De Regimine Principum*, written for Prince Hal shortly before his accession, is a tedious homily on the virtues and vices, imitated from Aegidius de Colonna's work of the same name, from the supposititious epistle of Aristotle, known as the *Secreta secretorum* and the work of Jacques de Cessoles (fl. 1300) rendered into English later by Caxton as *The Game and Playe of Chess*.

On the accession of Henry V. Occleve turned his muse to the service of orthodoxy and the Church, and one of his poems is a remonstrance addressed to Oldcastle, calling upon him to "ride up, a manly knight, out of the slough of heresy." Then a long illness was followed for a time, as he tells us, by insanity. His "Dialog with a Friend," written after his recovery, gives a naïve and pathetic picture of the poor poet, now fifty-three, with sight and mind impaired, but with hopes still left of writing a tale he owes his good patron, Humphrey of Gloucester, and of translating a small Latin treatise, *Scite Mori*, before he dies. His hopes were fulfilled in his moralized tales of "Jerusalem's Wife" and of "Jonathas," both from the *Gesta Romanorum*, which, with his "Learn to die," belong to his old age. After finally retiring from his privy seal clerkship, he was granted in 1424 sustenance for life in the priory of Southwick, Hants, on which, with his former annuity, he appears to have lived till about the middle of the century. A "Balade to my gracious Lord of Yorke" probably dates from 1448 or later.

The main interest for us in Occleve's poems is that they are characteristic of his time. They illustrate the blight that had fallen upon poetry on the death of Chaucer. The nearest approach to the realistic touch of his master is to be found in his "Male Regle," which, written about 1406, gives some interesting glimpses of his "misruly youth." But these pictures of 15th-century London are without even the occasional flash of humour that lightens up Lydgate's *London Lackpenny*.

A poem, "Ad beatam Virginem," generally known as the "Mother of God," and once attributed to Chaucer, is copied among Occleve's works in ms. Phillips 8151 (Cheltenham), and may thus be regarded as his work. Occleve found an admirer in the 17th century in William Browne, who included his "Jonathas" in the *Shepherds Pipe* (1614). Browne added a eulogy of the old poet, whose works he intended to publish in their entirety (*Works*, ed. W. C. Hazlitt, 1869, ii. 196-198). In 1796 George Mason printed six *Poems by Thomas Hoccleve never before printed*. . . ; "De Regimine Principum" was printed for the Roxburghe Club in 1860, and by the Early English Text Society in 1897. See Dr. F. J. Furnivall's introduction to *Hoccleve's Works; The Minor Poems, in the Phillips MS. 8151, and the Durham MS. III. 9*, ed. F. J. Furnivall; ii. *The Minor Poems in the Ashburnham MS. Addit. 133*, ed. Israel Gollancz; iii. *The Regement of Princes A.D. 1411-12, and fourteen of Hoccleve's minor poems*, ed. F. J. Furnivall (Early English Text Society, 3 vols., 1892-1925).

OCCULTATION, in astronomy, the hiding of one celestial body by another passing in front of it; commonly the passage of the moon or of a planet between the observer and a star or another planet.

OCCULTISM: see MAGIC.

OCEAN AND OCEANOGRAPHY. "Ocean" is the name applied to the great connected sheet of water which covers the greater part of the surface of the earth. But the ocean is less than the hydrosphere in so far as the latter term includes also the water lying on or flowing over the surface of the land. The conception of an encompassing ocean bounding the habitable world is found in the creation myths of the most ancient civilizations. The Babylonians looked on the world as a vast round mountain rising from the midst of a universal sheet of water. In the Hebrew scriptures the waters were gathered together in one place at the word of God, and the dry land appeared. The Ionian geographers looked on the circular disc of the habitable world

as surrounded by a mighty stream named Oceanus, the name of the primeval god, father of gods and men, and thus the bond of union between heaven and earth.

Since the Pythagorean school of philosophy upheld the spherical as against the disc-shaped world, some of the ancient geographers, including Eratosthenes and Strabo, looked upon the hydrosphere as forming two belts at right angles to each other, one belt of ocean following the equator, the other surrounding the earth from pole to pole as in the *terra quadrifida* of Macrobius; while others, including Aristotle and Ptolemy, looked upon the inhabited land, or *oikoumene*, as occupying the greater part of the earth's surface. Until the discovery of America and of the Pacific ocean the belief was general that the land surface was greater than the water surface. (See MAP.) Only in our own days has the existence of the southern continent been demonstrated within the limits of Antarctica.

Oceanography is the science which deals with the ocean. Of recent years the use of "hydrography" as the equivalent of physical oceanography has acquired a certain currency, but as the word is also used with more than one other meaning (see SURVEYING) it ought not to be used for oceanography. This article is restricted to general oceanography in its physical aspects and deals with phenomena common to the whole ocean.

History of Research and Organization.—Research in oceanography began in recent times, especially since the rapid increase in the study of the exact sciences during the 19th century. Observations at sea with accurate instruments became common, and the ships' logs of to-day are provided with headings for entering daily observations of the phenomena of the sea-surface. The contents of the sailors' scientific logs were brought together by the American enthusiast in the study of the sea, Matthew Fontaine Maury (1806-73), whose methods and plans were adopted at international congresses. Many millions of observations are recorded in ships' logs; this firsthand material is preserved in appropriate offices of various nations. The contents of these logs, it is true, refer more to maritime meteorology than to oceanography properly so-called.

This material for the study of the surface phenomena of the ocean has been supplemented in relation to the study of the depths of the ocean, by the records of numerous scientific expeditions and latterly by publications embodying systematic observations on a permanent basis. Valuable observations were made in oceanography during the expeditions of Captain James Cook and the polar explorers, especially those of Sir John Ross in the north and Sir James Ross in the south. The period of deep sea investigation began about 1850 when it became possible to measure ocean depths with precision. (See SOUNDING.) At this time, an exact knowledge of the depths of the ocean assumed an unlooked-for practical importance for the laying of telegraph cables at the bottom of the sea. Another stimulus came from the biologists, who began to realize the importance of a more detailed investigation of the life conditions of organisms at great depths in the sea.

These preliminary trips of scientific marine investigation were followed by the greatest purely scientific expedition ever undertaken, the voyage of H.M.S. "Challenger" round the world under the scientific direction of Sir Wyville Thomson and the naval command of Sir George Nares. This epoch-making expedition lasted from Christmas 1872 to the end of May 1876, and gave the first wide and general view of the physical and biological conditions of the ocean as a whole. Almost simultaneously with the "Challenger," a German expedition in S.M.S. "Gazelle" conducted observations in the south Atlantic, Indian and south Pacific oceans; and the U.S.S. "Tuscarora" made a cruise in the north Pacific, sounding out lines for a projected Pacific cable. Since that time investigation has been carried out by ships of all nations, on a scale too extensive for detailed record.

In 1902 at Stockholm was founded the International Council for the study of the sea, whose headquarters are in Copenhagen. At present (1928) all the north-east and north-west European States, with the exception of Russia, are represented there. The idea is to help and control the fisheries in the Baltic, the North

sea, the Norway sea and Barents sea, as well as in British and Irish waters. Portugal, Spain and Italy have also become members of this union, which has done much to improve the instruments and methods of oceanography. Generally, each Government has built or fitted out a research steamer for the work. The United States of America, Canada and Japan also take part.

Extent of the Ocean.—The hydrosphere covers nearly three-quarters of the earth's surface as a single and continuous expanse of water surrounding four great insular land-masses known as the continents. Water predominates in the unexplored north polar area, and it is very unlikely that new land of any great extent exists there. On the other hand, recent antarctic exploration makes it certain that a great continent surrounds the south pole with a total area of about 14,000,000 sq.km. Thus there is a total land area of 148,892,000 sq.km., and a total water area of 361,059,000 sq.km., 29% of land and 71% of water, or a ratio of 1:2.43.

Divisions of the Ocean.—The arrangement of the water surface on the globe is far from uniform, the ocean forming 61% of the total area of the Northern and 81% of that of the Southern Hemisphere. Of the whole ocean only 43% (154.7 million sq.km.) lies in the Northern Hemisphere and 57% (206.4 million sq.km.) in the Southern. A great circle can be drawn upon a globe in such a way as to divide it into two hemispheres, one of which contains the greatest amount of land and the other the greatest amount of sea of any possible hemispheres. The centre of the so-called land hemisphere lies near the mouth of the Loire (47½° N. and 2½° W.), while the centre of the so-called water hemisphere lies to the south-east of New Zealand and eastward of Antipodes island. Even in the land hemisphere the water area (135.6 million sq.km.) is in excess of the land area (119.4 million sq.km.), while in the water hemisphere the amount of land is quite insignificant, 29.6 million sq.km. compared with 225.4 million sq.km. of water.

The outline of the water surface depends on the outline of the basins in which it is contained. The four great continental masses, therefore, give the ocean a distinctly tripartite form, the three great divisions being known as the Atlantic, the Indian and the Pacific oceans, all three running together into one around Antarctica. Thus the connecting belt of water is narrow as compared with the extent of the oceans from north to south. The proportions are not readily grasped from a map of the world on Mercator's projection and must be studied on a globe.

Each of the three meridional oceans has an Antarctic facies in the southern part. Some authors prefer to consider these southern parts as a Great Southern ocean. Only the Atlantic possesses a really Arctic facies north from the narrowest part of Davis strait, north of Denmark strait and north of a line running from Iceland to Jan Mayen and Spitzbergen.

Where the ocean touches the continents the margin is in places deeply indented by peninsulas and islands marking off portions of the water surface which from all antiquity have been known as "seas." These seas are more or less dependent on the ocean for their régime, being filled with ocean water. These seas may be classified according to their form either as "enclosed" or as "partially enclosed" (or "fringing"). Enclosed seas extend deeply into the land and originate either by the breaking through of the ocean or by the overflowing of a subsiding area. They are connected with the ocean by narrow straits, the salinity of the water contained in them differs in a marked degree from that of the ocean, and the tidal waves are of small amplitude. Four great intercontinental enclosed seas are included between adjacent continents—the Arctic sea, the Central American or West Indian sea, the Australo-Asiatic or Malay sea and the Mediterranean sea. There are also four smaller continental enclosed seas each with a single channel of communication with the ocean, viz., the Baltic sea and Hudson bay with very low salinity, the Red sea and Persian gulf with very high salinity.

The fringing or partially enclosed seas adjoin the great land masses and are only separated from the oceans by islands or peninsulas. Hence their tidal conditions are quite oceanic, though their salinity is usually rather lower than that of ocean water. The four fringing seas of eastern Asia parallel the main lines of dis-

location in the neighbouring land masses, as do the Andaman sea and the Gulf of California. On the contrary, the North sea, the British fringing seas, and the Gulf of St. Lawrence cross the main lines of dislocation.

In addition to these seas notice must be taken of the subordinate marginal features, such as gulfs and straits. Gulfs may be classified according to their origin as due to fractures of the crust or overflowing of depressed lands. The former are either the extensions of oceanic depressions, *e.g.*, the Arabian sea, or such caldron-depressions as the gulf of Genoa or rift-depressions like the Gulf of Aden. Compound gulfs are formed seawards by fracture and landwards by the overflowing of depressed land, *e.g.*, the Bay of Biscay, Gulf of Alaska and Gulf of the Lion. Gulfs formed by the overflowing of depressed lands lie upon the continental shelf, *e.g.*, the Gulf of Maine, Bay of Fundy.

Straits have been formed (1) by fracture across isthmuses, longitudinally as in the Strait of Bab-el-Mandeb, or transversely as in the Strait of Gibraltar; (2) by erosion, *e.g.*, the Strait of Dover; (3) by overflowing subsided land, as in the straits of Bering, Torres and Formosa.

Surface of the Ocean.—If the whole globe were covered with a uniformly deep ocean and if it were of uniform density, the surface would form a perfect ellipsoid of revolution. At any point a sounding line would hang in the line of the radius of curvature of the water surface. But the water surface is broken by land, and the mean density of the substance of the land is 2.6 times as great as that of sea-water, so that the gravitational attraction of the land must necessarily cause a heaping up of the sea around the coasts, forming what has been called the continental wave, and leaving the sea-level lower in mid-ocean. Hence the geoid or figure of the sea surface is not part of an ellipsoid of rotation but irregular. The differences of level between different parts of the geoid have been greatly overestimated in the past; F. G. Helmert has shown that they cannot exceed 200 metres and are probably much less. Recent pendulum observations have shown great local differences in density in the earth's crust, a marked deficiency of mass under high mountains and excess under the bed of the ocean. There is thus a condition of isostasy or equilibrium between them as a general rule. The intensity of gravity at the surface of the sea far from land has been measured on several occasions. The inequalities of the geoid are not over 100 metres. Distortion of the ocean surface may also arise from meteorological causes and be periodic or unperiodic in its occurrence, but it does not amount to more than 1 or 2 metres. Atmospheric precipitation poured into the sea by the great rivers must necessarily create a permanent rise of the sea-level at their mouths, and from this cause the level round the coasts of rainy lands must be higher than in mid-ocean. The level of the Skagerak should be about 0.6 metre higher than that of the open Norwegian sea between Jan Mayen and the Lofoten islands, the level of the Gulf of Finland at Kronstadt and of the Gulf of Bothnia at Haparanda should similarly be 0.4 metre higher than that of the Skagerak. The level of the Mediterranean has also been determined by exact measurements to be from 0.4 to 0.6 metre lower than that of the Atlantic on account of evaporation. The atmosphere affects sea-level also by its varying pressure, the difference in level of the sea surface from this cause between two given points being 13 times as great as the difference between the corresponding readings of the mercurial barometer. In the north tropical belt of high pressure south of the Azores the atmospheric pressure in January is 22mm. higher than in the Irminger sea; hence the sea-level near the Azores is almost 0.3 metre lower than in the northern sea. The Baltic is fuller in the time of the summer rains than in winter, when the rivers and lakes are frozen and most of the precipitation on the land is snow. A similar range occurs on the Dutch coast in the North sea, where the maximum level is reached in October, the month of highest rainfall, and there is a range of 200mm. to the minimum level at the time of least rainfall in early spring.

In the monsoon regions the half-yearly change from on-shore to off-shore winds produces noticeable differences in level, the total range being 237mm. The influence of wind on water-level is

most remarkable in heavy storms on the flat coasts of the North sea and Baltic, when the rise may amount to very many feet. In the region of tropical hurricanes the converging wind system of a circular storm causes a heaping up of water capable of devastating the low coral islands of the Pacific. The old speculations as to a great difference of level between the Mediterranean and the Red sea, and on the two sides of the Isthmus of Panama, have been proved by precision levelling to be totally erroneous.

Deep-sea Soundings.—The hand-lead attached to a line divided into fathoms was a well-known aid to navigation even in high antiquity, and its use is mentioned in Herodotus (ii. 5) and Acts (xxvii. 29). The earliest deep-sea sounding on record is that of Capt. Phipps on Sept. 4, 1773, in the Norwegian sea, in 65° N. 3° E., on his return from his expedition to Spitsbergen. He spliced together all the sounding-lines on board, and with a weight of 150lb. attached he found bottom in 683 fathoms and secured a sample of fine soft blue mud. He detected the moment of the lead touching the bottom by the sudden slackening in the rate at which the line ran out. The honour of first sounding really oceanic depths belongs to Sir James Clark Ross, who made some excellent measurements in very deep water using expensive kilometre-long stout hemp lines. Captain Matthew Fontaine Maury, U.S.N., introduced a ball of strong twine attached to a cannon shot, which ran it out rapidly; when the bottom was reached the twine was cut and the depth deduced from the length of string left in the ball on board. The time of touching bottom was judged by timing each 100-fathom mark and noting the sudden increase in the time interval when the shot reached the bottom. In 1854, J. M. Brooke, a midshipman of the United States Navy, invented a method of sounding by means of an automatically released heavy weight.

Modern surveying ships sound with steel piano wire not more than 0.6 to 0.9mm. in diameter and a detachable lead seldom weighing more than 70lb. (See SOUNDING.)

Since 1920 the acoustic method has been used to measure the ocean depths. The first results are satisfactory and the so-called "echo-data" are increasing rapidly in number and value. When the sound wave is engendered in the water, one must measure the time (in seconds) which the wave takes to reach the sea bottom and the time the echo takes to get back from there to the ship. The speed of the sound increases with the temperature, with the salt content and with the pressure, and varies between 1,400 and 1,620 metres per second. Generally the results of echo-observations and wire loosening are in fairly close agreement; but formerly one was not sure whether the wire dropped vertically or whether it was deflected by currents and thus registered too great a depth.

Relief of the Ocean Floor.—Recent soundings have shown that the floor of the ocean on the whole lies some 3 or 4 km. beneath the surface and E. Kossinna has, 1921, calculated the mean depth to be 3,800 metres, while the mean elevation of the surface of the continents above sea-level is only 840 metres. Viewed from the floor of the ocean the continental block would thus appear as a great plateau rising to a height of 4,640 metres. The greatest depths of the ocean below sea-level and the greatest heights of the land above it are not of the same order of magnitude, the summit of Mt. Everest rising to 8,800 metres above the sea-level, while the Philippine Trench near Mindanao sinks to 10,800 metres (5,900 fathoms) below sea-level. Of course the area at great heights is very much less than the area at corresponding depths. According to Kossinna's calculation the areas of the ocean beyond various depths are as follows:—

Metres	Millions sq. km.	$\frac{C}{100}$ of 361.06 million sq. km.
More than		
200 . . .	333.5	65.3
1,000 . . .	318	62.3
2,000 . . .	303	59.4
3,000 . . .	278.5	54.6
4,000 . . .	207.5	40.7
5,000 . . .	88.5	17.4
6,000 . . .	4.5	0.9

Considering these areas and those of continental lands of various elevations, it is possible to classify the whole into three groups, (1) the area of the continents and their shelves down to the 200 metre submarine contour, this makes up 34.7% of the earth's surface; (2) The area between the 200 metre and 3,000 metre submarine contour, 10.7% of the earth's surface; (3) The area below the 3,000 metre submarine contour, 54.6% of the earth's

FIG. 1

surface. (Fig. 1.) If land and water were evenly balanced on the earth the most widespread depth figure for the ocean should be about 2,400 metres, but the actual facts are surprisingly different. Several students, including A. Wegener, interpret matters by supposing that the continental masses are of material different from that of the deep-sea floor. The first, which they call sial, rich in silica, has a specific gravity of 2.6. The second, which they call sima, is formed of basic material and has a specific gravity of 2.9. They think that the continental masses float in the deep-sea floor rocks, much as icebergs float in the sea. This interpretation makes the deep-sea floor something quite different from the continents and is, at any rate, a useful working hypothesis. On the whole the floor of the ocean is not so smooth in its contours as had been believed until recently. According to the new "echo data" the apparent great flat stretches show marked variations of relief. Modern orometry has introduced the calculation of the mean angle of the slope of a given uneven surface provided that maps can be prepared showing equidistant contour lines. If the distance between the contour lines is h and the length of the individual contour lines l , the sum of their lengths $\Sigma(l)$, and A the area of the surface under investigation, then the mean angle of slope is obtained from the equation

$$\alpha = \frac{h \Sigma(l)}{A}.$$

Calculating from sheets of the prince of Monaco's *Atlas of Ocean Depths*, Krümmel obtained a mean angle of slope of $0^\circ 27' 44''$ or an average fall of 1 in 124 for the north Atlantic between 0° and 47° N., the enclosed seas being left out of account. Large angles of slope may, however, occur on the flanks of oceanic islands and the continental borders. On the submarine slopes leading up to isolated volcanic islands, angles of 15° to 20° are not uncommon, at St. Helena the slopes run up to $38\frac{1}{2}^\circ$ and even 40° , at Tristan d'Acunha to $33\frac{1}{2}^\circ$. E. Hull found a mean angle of slope of 13° to 14° for the edge of the continental shelf off the west coast of Europe, and off Cape Torifana ($43^\circ 4' N.$) as much as 34° . Where the French telegraph cable between Brest and New York passes from the continental shelf of the Bay of Biscay to the depths of the Atlantic the angle of slope is from 30° to 41° . Such gradients are of a truly mountainous character; the angle of slope from the Eibsee to the Zugspitze is 30° . Particularly steep slopes are found in the case of submarine domes, usually incomplete volcanic cones, and there have been cases in which after such a dome has been discovered by the soundings of a surveying ship it could not be found again as its whole area was so small and the deep floor of the ocean from which it rose so flat that an error of 4 or 5 km. in the position of the ship would prevent any irregularity of the bottom from

appearing.

In spite of the increase of deep-sea soundings in the last few decades, they are still very irregularly distributed in the open ocean, and the isobaths (lines of equal depth) on a chart of the world include wide generalizations. Bearing this caution in mind, the existing bathymetrical charts, amongst which that of the prince of Monaco stands first, give a very fair idea of the great features of the bed of the oceans. (*Carte générale bathymétrique des océans dressée par ordre de S.A.S. le Prince Albert de Monaco*, 24 sheets [Paris, 1904]; 2nd edition, Paris, 1913 seq.) A definite terminology for the larger forms of sub-oceanic relief was put forward by the International Geographical Congress at Berlin in 1899 and adopted by that at Washington in 1904. Equivalent terms, which are not necessarily identical or literal translations, were adopted for English, French and German.

The larger forms designated by special generic terms include the following: The *continental shelf* is the gentle slope which extends from the edge of the land to a depth usually about 100 fathoms or 200 metres, though in some cases as much as 300 fathoms or about 600 metres, and is there demarcated by an abrupt increase in the steepness of the slope to ocean depths. In the deep sea two types of feature are recognized under the general names of *depression* and *elevation*. The depression is distinguished according to form and slope as (1) a *basin* when of a roughly round outline, (2) a *trough* when wide and elongated, or (3) a *trench* when narrow and elongated lying along the edge of a continent. The extension of a basin or trough stretching towards the continent is termed an *embayment* when relatively wide and a *gully* when narrow. The elevation includes (1) the gently swelling *rise* which separates troughs and basins in the middle of the ocean, (2) the steeply sloping *ridge* which interposes a narrower barrier between two depressions, and (3) the *plateau* or wide elevation rising steeply on all sides from a depression. The deepest part of a depression is termed a *deep*, and the highest part of an elevation when not reaching the surface a *height*. In addition to these larger forms a few minor forms must be recognized. Amongst these are the *dome*, an isolated elevation rising steeply but not coming within 100 fathoms (200 metres) of the surface; the *bank*, an elevation coming nearer the surface than 100 fathoms, but not so near as 6 fathoms (10-11 metres); and finally the *shoal* or *reef*, which comes within 6 fathoms of the surface, and so may constitute a danger to shipping. Similarly we may note the *caldron* or small steep depression of a round outline, and the *furrow* or long narrow groove in the continental shelf.

According to the resolutions of the International Geographical Congress the larger individual forms which have been described by generic terms shall have specific names of a purely geographical character; but in the case of the minor forms the names of ships and persons are considered applicable. In 1899 A. Supan published a chart of the oceans with a suggested nomenclature based on these principles; and the larger forms in the prince of Monaco's great chart also are named in accordance with the rule. This system is not yet general. Sir John Murray considers that only deeps exceeding 3,000 fathoms in depth should be named.

The Continental Shelves.—The continental shelves are those parts of the continental blocks which have been covered by the sea in comparatively recent times, and their surface consequently presents many similarities to that of the land, modified of course by the destructive and constructive work of the waters. Waves and tidal currents produce their full effects in that region, and in high latitudes the effect of transport of materials by ice is very important; while in the warm water of the tropics the reef-building animals and plants (corals and calcareous algae) carry on their work most effectively there. The continental shelves include not only the oceanic border of the continents but also great areas of the enclosed seas and particularly of the fringing seas, the origin of which through secular subsidence is often very clearly apparent, as for instance in the North sea and the tract lying off the mouth of the English channel. A closer investigation of the numerous long narrow banks which lie off the Flemish coast and the Thames estuary shows that they are composed of fragments of rock abraded and transported by tidal currents and

storms. Numerous old river valleys and furrows entrenched in the continental shelf bear witness to its land origin. Such valleys are very clearly indicated in the belts of the western Baltic, the Cape Breton deep, the Hudson Furrow, the so-called Congo Cañon, the Swatch of No Ground off the Ganges delta, and numerous similar furrows.

The seaward edge of the continental shelf often falls steeply to the greatest depths of the ocean, and not infrequently forms the slope of a *trench*, a form of depression which has usually a steep slope towards a continent or an island-bearing rise on one side and a gentler slope towards the general level of the ocean on the other. Soundings exceeding 7,000 metres occur in trenches; there are few trenches known (on west coast of Central America) in which the maximum depth is less than 5,000 metres. Most trenches are narrow, but of considerable length, and their steeper side is believed to be due, not to a fracture, but to a folding of the earth's crust, because these trenches are only found parallel to young fold mountains like the Cordillera of North and South America. The deep trenches are distributed chiefly around the Pacific near to the shore or near the limits of former lands (Mindanao, 10,800m.). Outside the Pacific we find a trench (8,526m.) north of Porto Rico, and another north of the south Sandwich Islands in the south Atlantic. In the Indian ocean there is a trench (7,450m.) west and south of Sumatra-Java, where a double-folding occurs. On a coast with old block mountains, as around Africa and the Deccan, these trenches are absent. The region of these depressions is also specially subject to great earthquakes. These submarine trenches occupy only 1% of the area of the oceans. There are also numerous "fossil" trenches, filled with various deposits, at the foot of fold mountains, as, for example, the Ganges valley.

TABULAR VIEW OF OCEANS AND SEAS

The following table gives the average depth, the area, and the volume of the oceans, seas and the hydrosphere according to the 1921 computations of E. Kossinna:—

Mean Depth, Area and Volume of Oceans and Seas.

Name	Depth		Area	Volume
	Metres	Fathoms	Sq. km.	Cu. km.
Atlantic ocean	3,926	2,147	82,441,500	323,613,000
Indian ocean	3,963	2,167	73,442,700	291,030,000
Pacific ocean	4,282	2,342	165,246,200	707,555,000
I. Oceans	4,117	2,251	321,130,400	1,322,198,000
Arctic sea	1,205	659	14,090,100	16,980,000
Malay sea	1,212	663	8,143,100	9,873,000
Central American sea	2,216	1,212	4,319,500	9,573,000
Mediterranean sea	1,429	782	2,965,900	4,238,000
Inter-continental seas	1,378	754	29,518,600	40,664,000
Baltic sea	55	30	422,300	23,000
Hudson bay	128	70	1,232,300	158,000
Red sea	491	269	437,900	215,000
Persian gulf	25	14	238,800	6,000
Smaller enclosed seas	172	94	2,331,300	402,000
II. Enclosed seas	1,289	705	31,849,900	41,066,000
Bering sea	1,437	786	2,268,200	3,259,000
Okhotsk sea	838	458	1,527,600	1,279,000
Japan sea	1,350	738	1,007,700	1,361,000
East China sea	188	103	1,249,200	235,000
Andaman sea	870	476	797,600	694,000
Californian gulf	813	445	162,200	132,000
North sea	94	52	575,300	54,000
English channel and Irish sea	58	32	178,500	10,000
Laurentian sea	127	70	237,800	30,000
Bass sea	70	39	74,800	5,000
III. Fringing seas	874	478	8,078,000	7,059,000
Seas (enclosed and fringing)	1,205	659	39,928,800	48,125,000
Hydrosphere	3,795	2,075	361,059,200	1,370,323,000

Oceanic Deposits.—It has long been known that the deposits which carpet the floor of the ocean differ in different places, and coasting sailors have been accustomed from time immemorial to use the lead not only to ascertain the depth of the water but also to obtain samples of the bottom, the appearance of which is often characteristic of the locality. Various devices have been attached to leads intended to catch and hold the material when soft enough to be penetrated. One of the most effective early forms was the snapper or "deep-sea clamm" of Sir John Ross, a pair of powerful spring jaws held apart by an arrangement which, when released on striking the bottom, allowed the jaws to close, biting out and holding securely a substantial portion of the ground. A simpler form of collector, now almost universally used, is a plain brass tube, which is driven into the bottom of the sea by the weight of the sounding lead, and in which the deposit may be retained by a valve or other contrivance, though in many cases friction alone suffices to hold the punched-out core. Larger quantities of deposit may be conveniently collected by means of the Monaco snapper or of the dredge, which can be worked in any depth and brings up large stones, concretionary nodules or fossils, which a sounding-tube could not collect.

The voyage of the "Challenger" supplied for the first time the nucleus of a collection of deep-sea deposits sufficient to serve as the basis for comprehensive classification and mapping. The "Challenger" collections supplemented by those of other expeditions and of many telegraphic and surveying-ships were studied in detail by Sir John Murray and Prof. A. Renard, whose monograph ("*Challenger*" Reports, "Deep Sea Deposits"), published in 1891, laid the foundations and reared the greater part of the structure of our present knowledge on the subject. The classification adopted was a double one, thus:—

I. Deep sea deposits (beyond 100 fathoms or 200 metres)	1. Red clay	A. Pelagic deposits (formed in deep water remote from land)
	2. Radiolarian ooze	
	3. Diatom ooze	
	4. Globigerina ooze	
	5. Pteropod ooze	
	6. Blue mud	
	7. Red mud	
	8. Green mud	
	9. Volcanic mud	
	10. Coral mud	
II. Shallow water deposits (in less than 100 fathoms)	Sands, gravels, muds, etc.	B. Terrigenous deposits (formed in deep or shallow water close to land)
III. Littoral deposits (between high and low-water marks)	Sands, gravels, muds, etc.	

Krömmel preferred, 1907, to simplify this by grouping the deposits in a single category arranged according to position:

(a) *Littoral* (including Murray and Renard's littoral and shallow water deposits [II. and III.]).

(b) *Hemipelagic* (including Nos. 6-10 of deep sea deposits).

(c) *Eupelagic* (including Nos. 1-5 of deep sea deposits).

As so defined the hemipelagic deposits are those which occur in general on the slope from the continental shelves to the ocean depths and in the deep sea basins of enclosed and fringing seas. K. Andrée (*Geologie des Meeresbodens*, 1920) adopts this.

Littoral and Shore Deposits.—The littoral deposits include those of the actual shore on the wash of the waves and of the surface of the continental shelf. Shore deposits are the product of the waste of the land arranged and bedded by the action of currents or tidal streams. On the rocky coasts of high latitudes blocks of stone detached by frost fall on the beach, and becoming embedded in ice during winter, are often drifted out to sea and so carry the shore deposits to some distance from the land. Where the force of the waves on the beach produces its full effect the coarser material gets worn down to gravel, sand and silt, the finest particles remaining long suspended in the water, to be finally deposited as mud in quiet bays. A particularly fine-grained mud is formed on the low coasts of the eastern border of the North sea by a mixture of the finest sediment carried down by the slow-running rivers with the calcareous or siliceous remains of plankton. Pure calcareous sand and calcareous mud are formed by

wave action on the shores of coral islands where the only material available is coral and the accompanying calcareous algae, crustacea, molluscs and other organisms secreting carbonate of lime. Recent limestones are being produced in this way and also in some places by the precipitation of calcium carbonate by sodium or ammonium carbonate which has been carried into the sea or formed by organisms. The precipitated carbonate may agglomerate on mineral or organic grains which serve as nuclei, or it may form a sheet of hard deposit on the bottom, as occurs in the Red sea, off Florida, and round many coral islands in the Pacific. The very finest sediment is kept in a state of movement until it drops into the gulleys or furrows of the shelf, where it can come to rest together with the finer fragments of the remains of littoral or bank vegetation. Thus are formed the "mud-holes" of the Hudson Furrow. Sand may be taken as the predominating deposit on the continental shelves, often with a large admixture of remains of calcareous organisms, for instance the deposits of *maërl* made up of nullipores off the coasts of Brittany and near Belle Isle. Amongst the most widely-distributed of the deposits actually formed on the continental shelf are phosphatic nodules; these are especially abundant on the east coast of the United States and on the Agulhas bank, where the amount of calcium phosphate in the nodules is as much as 50%. Sir John Murray finds the source of the phosphoric acid to be the decomposition of large quantities of animal matter.

Hemipelagic Deposits.—These are a mixture of deposits of terrigenous and pelagic origin. The most abundant of the terrigenous materials are the finest particles of clay and calcium carbonate as well as fragments derived from land vegetation, of which twigs, leaves, etc., may form a perceptible proportion as far as 350 to 400 km. from land. Blue mud, according to Murray and Renard, is usually of a blue or slatey or grey-green colour when fresh, the upper surface having, however, a reddish tint. The proportion of calcium carbonate varies greatly according to the amount of foraminifera and other calcareous organisms it contains. Blue mud prevails in large areas of the Pacific ocean, the Indian ocean, and the Atlantic. As a glacial-marine mud it occurs round the whole of the Antarctic shelf, down to depths of 4,500 metres. A blue and brown mud is the chief deposit of the North Polar basin and of the Norwegian sea also. Max Weber states that blue mud occurs in the deep basins of the eastern Malay sea.

Red mud may be classed as a variety of blue mud, from which it differs on account of the larger proportion of ochreous substance. This variety surrounds the tropical parts of the continental shelves of South America, South Africa and eastern China.

Green mud differs to a greater extent from the blue mud, and owes its characteristic nature and colour to the presence of glauconite, the spines of echini and the spicules of sponges. It occurs in such abundance in certain geological formations as to give rise to the name of green-sand. Green mud abounds off Cape Hatteras, the north of Cuba, and off the coast of California. The "Challenger" expedition found it on the Agulhas bank, on the eastern coasts of Australia, Japan, South America and on the west coast of Portugal. When the proportion of calcium carbonate in the blue mud is considerable a calcareous ooze results. The floors of the Caribbean, Cayman and Mexican basins in the Central American sea are covered with a white calcareous ooze with calcareous concretions. Similar formations are found in the Mediterranean, where a dark mud predominates in the western part, passing into a grey, marly slime in the Tyrrhenian basin and replaced by a calcareous ooze in the Eastern basin. The bottom of the Black sea is covered by a stiff blue mud. Sir John Murray found pyrites make up nearly 50% of the deposit. In the Red sea the "Pola" expedition discovered a calcareous ooze similar to that of the Mediterranean, and the formation of stony crust by precipitation of calcium and magnesium carbonates may be recognized as giving origin to a recent dolomite.

The terrigenous ingredients in the deposits become less and less abundant as one goes farther into the deep ocean. Finely-divided colloidal clay is found in all parts of the ocean, however remote from land, in very small amount, and there is less in tropical than

in cooler waters. There is present in sea-water far from land a different clay derived from the decomposition of volcanic materials. To this very slowly-growing deposit of inorganic material over the ocean floor there is added an overwhelmingly more rapid contribution of the remains of calcareous and siliceous planktonic and benthonic organisms, which tend to bury the slower accumulating material under a blanket of globigerina, pteropod, diatom or radiolarian ooze. When those deposits of organic origin are wanting or have been removed, the red clay composed of the mineral constituents is found alone. It is a remarkable geographical fact that on the rises and in the basins of moderate depth of the open ocean the organic oozes preponderate, but in the abyssal depressions below 5,000 metres there is found only the red clay, with a minimum of calcium carbonate, though sometimes with a considerable admixture of the siliceous remains of radiolarians.

Eupelagic Deposits.—Globigerina ooze was recognized as an important deposit as soon as the first successful deep-sea soundings had been made in the Atlantic. Murray and Renard define globigerina ooze as containing at least 30% of calcium carbonate, in which the remains of pelagic (not benthonic) foraminifera predominate. In many parts of the Atlantic, as Lohmann points out, 70% of the globigerina ooze consists of coccoliths (minute calcareous algae). The striking absence of mineral constituents distinguishes the eupelagic globigerina ooze from the hemipelagic calcareous mud. Out of 118 samples of globigerina ooze by the "Challenger" expedition, 84 came from depths of 3,000 to 4,500 metres, and only 16 from depths greater than 4,500 metres. Viewed as a whole, this deposit may be taken as a partial precipitation of the plankton living in the upper waters of the open sea. Globigerina ooze is the characteristic deposit of the Atlantic ocean, where it covers not less than 48,500,000 sq. kilometres. In the Indian ocean the area covered is 31,000,000 sq. km., and in the huge Pacific ocean only 30,000,000 sq. kilometres.

Pteropod Ooze.—This is merely a local variety of globigerina ooze in which the comparatively large but very delicate spindle-shaped shells of pteropods happen to abound. These shells do not retain their individuality at depths greater than 3,000 metres, and, in fact, pteropod ooze is only found in small patches on the ridges.

Diatom Ooze.—This was recognized by Sir John Murray as the characteristic deposit in high latitudes in the Indian ocean, and later it was found to be characteristic also of the corresponding parts of the Atlantic and Pacific, covering a total area of about 23,000,000 sq. kilometres. It is in these latitudes not seldom combined with marine glacial deposits. It has been found sporadically near the Aleutian islands, between the Philippines and Marianne islands and to the south of the Galapagos group. It is made up to a large extent of the siliceous frustules of diatoms. It is usually yellowish-grey and often straw-coloured when wet, though when dried it becomes white and mealy.

Red Clay.—This was discovered and named by Sir Wyville Thomson on the "Challenger" in 1873 when sounding in depths of 5,000 metres and more on the way from the Canary islands to St. Thomas. The reddish colour comes from the presence of oxides of iron, and particles of manganese also occur in it, especially in the Pacific region, where the colour is more that of chocolate; but when it is mixed with globigerina ooze it is grey. Red clay is the deposit peculiar to the abyssal area; 70 carefully investigated samples collected by the "Challenger" came from an average depth of 5,000 metres. Red clay has not yet been found in depths less than 3,500 metres. The main ingredient of the deposit is a stiff clay which is plastic when fresh, but dries to a stony hardness. Isolated gritty fragments of minerals may be felt in the generally fine-grained homogeneous mass. The dredge often brings up large numbers of nodules formed upon sharks' teeth, the ear-bones of whales or turtles, or small fragments of pumice or other volcanic ejecta, and all more or less incrustated with manganese oxide until the nodules vary in size from that of a potato to that of a man's head. A very interesting feature is the small proportion of calcium carbonate, the amount present being usually less as the depth is greater; red clay from depths exceeding 5,500 metres does not contain so much as 1% of calcareous matter. The

red clay is the characteristic deposit of the Pacific ocean, where about 101,000,000 sq.km. are covered with it, while only 15,000,000 sq.km. of the Indian ocean and 14,000,000 sq.km. of the Atlantic are occupied by this deposit; it is, indeed, the dominant submarine deposit of the water-hemisphere, just as globigerina ooze is the dominant submarine deposit of the land-hemisphere.

Radiolarian Ooze.—This was recognized as a distinct deposit and named by Sir John Murray on the "Challenger" expedition, but it may be viewed as red clay with an exceptionally large proportion of siliceous organic remains, especially those of the radiolarians which form part of the pelagic plankton. It does not occur in the Atlantic ocean at all, and in the Indian ocean it is only known round Cocos and Christmas islands; but it is abundant in the Pacific.

Murray and Renard recognized a progressive diminution of carbonate of lime with increase of depth as a characteristic of all eupelagic deposits. The whole collection of 231 specimens of deep sea deposits brought back by the "Challenger" shows the following general relationship:—

Proportion of Calcium Carbonate in Deep Sea Deposits

68 samples from less than 2,000 fathoms (3,600 metres)	= 60-80%
68 samples from 2,000-2,500 fathoms (3,600-4,600 metres)	= 46-76%
65 samples from 2,500-3,000 fathoms (4,600-5,500 metres)	= 17-46%
8 samples from more than 3,000 fathoms (5,500 metres)	= 0-9%

New studies of the "Meteor" expedition show that near the great depths the configuration of the floor plays an important part. Where, as a result of an elevation of the ocean floor, the water in a basin is stagnant or moves only slowly, e.g., in the Congo deep, north of the Walfisch ridge, the diminution of the calcium carbonate with increasing depth is much less marked than where the ground currents bring a continuous inflow of new water. Thus we find in the floor deposits at about 5,000 metres depth west of the mid-Atlantic ridge in the Brazil deep only 2% of calcium carbonate, while eastward in the Congo deep we have 46%.

Opinions are still varied as to the time necessary for the formation of 1 cm. or 1 ft. of deep sea deposit. It is generally believed that the red clay accumulates extremely slowly because sharks' teeth and whales' ear-bones which serve as nuclei in it belong, in some cases, to extinct species and are not found in the globigerina ooze, although there is no reason to suppose that at any one time they were unequally distributed over the ocean floor. Cable engineers report that a layer of globigerina ooze 2 cm. thick can be formed in ten years. For 2 cm. of coccolith ooze to be formed, however, it is computed that 4,000 years are necessary.

The frequently observed stratification within a sample is also important. All samples are not homogeneous, one of 50 cm. depth can include very varied deposits. In some samples sand which can be deposited only near a coast is found under a layer of globigerina ooze, whence it is evident that the study of marine deposits is of great importance in connection with investigations of geomorphological evolution.

Permanence of the Ocean Beds.—There are no known sedimentary rocks that appear to have been deposited at the bottoms of oceans comparable in depths with those we know—that is, there are no formations known that resemble, for instance, the globigerina ooze now being deposited on the Atlantic floor. On the other hand, the geographical distribution of many species of plants and animals points very decidedly towards the existence in the past of land connections between the various continents, and this evidence cannot be put aside. It was therefore given as another theory by Neumayer, Frech and others (1885, 1902) that, in the north and south Atlantic, in the central part of the Indian ocean, and possibly in the central part of the Pacific, there were, during the Mesozoic period, extensive land regions that have now subsided. Thus there are indications that large regions of continental land have been depressed to form the floors of deep oceans, but there are no clear indications that deep ocean beds have ever been elevated to form dry land.

A third hypothesis set out by A. Wegener in 1915, suggests that the great continental land elevations actually slip on the plastic layer beneath. The Atlantic basin has been formed by the slipping

westward of the Americas. The coastal mountain ranges on the Pacific margin of the Americas were formed by the crumpling of the crust under the westward drift of the American continents, and so on. The hypothesis requires that there should be evidence of progressive change of longitude. Observed changes are doubted. It also requires some stress-difference under which the continental land masses yield and shift place relative to the earth-axis. All these three very different theories—that of permanence, that of bridge continents and that of slipping continents—have their difficulties and objections. It follows that there can be no agreement as to the age of the oceans.

AGE OF THE OCEANS

According to Wegener the Atlantic is the youngest, the Indian older, and the Pacific the oldest of the oceans. Certainly the Atlantic, in the zone stretching from the West Indies to the Mediterranean, has experienced great changes since Tertiary times. Other investigators suggest that the Atlantic, with the exception of the West Indian region, is the oldest ocean, and that the Pacific is still, so to speak, in the making. As proofs of this are mentioned the many deep trenches or geosynclines around its borders and the numerous earthquakes which point to the continuation of the folding and subsidence. Some data now exist for the formation of estimates of the age of the oceans. The evidence comes partly from the study of radioactivity (*q.v.*); it is known that helium and lead are the end-products of radioactive disintegration of certain minerals, and from the ratios of these materials to their parent substances it is believed that a period of several thousands of millions of years must have elapsed since the first solid and cool earth-crust was formed. Some cosmographic investigations (due mainly to Jeans and Jeffreys) suggest that at least about 1,300,000,000 years have elapsed since the first oceans were formed.

Salts of Sea Water.—Common salt, Epsom salts, gypsum and magnesium chloride were early recognized amongst the constituents of sea water. Modern analyses reveal the existence of 32 out of the 80 known elements as dissolved in sea water. Copper, lead, zinc, nickel, cobalt and manganese have been found only in the substance of sea weeds and corals. Silver and gold also exist in solution in sea water. E. Sonnstadt detected first, in 1870, gold by means of a colour test, Haber's analyses 1926-27 give 4 (10⁻⁶) grains of gold per kgm. of sea water, making any ideas of recovery hopeless.

The elements in addition to oxygen which exist in largest amount in sea salt are chlorine, bromine, sulphur, potassium, sodium, calcium and magnesium. Since the earliest quantitative analyses of sea water were made by Lavoisier in 1772 the view has been held that the salts are present in sea water in the form in which they are deposited when the water is evaporated. The most numerous analyses have been carried out by Forchhammer, who dealt with 150 samples, and Dittmar, who made complete analyses of 77 samples obtained on the "Challenger" expedition. Dittmar found the following average proportions of the salts in ocean water:—

The Salts in Ocean Water

	Per 1,000 parts water	% Total salts	Per 100 molecules MgBr ₂
Common salt, sodium chloride (NaCl)	27.213	77.758	112.793
Magnesium chloride (MgCl ₂)	3.807	10.878	9.690
Magnesium sulphate (MgSO ₄)	1.658	4.737	3.338
Gypsum, calcium sulphate (CaSO ₄)	1.260	3.600	2.239
Potassium sulphate (K ₂ SO ₄)	0.803	2.465	1.200
Calcium carbonate (CaCO ₃) and residue	0.123	0.345	.298
Magnesium bromide (MgBr ₂)	0.076	0.217	1.00
	35.000	100.000	

The variations in the proportion of individual salts to the total salts are very small; all analyses since Dittmar's have confirmed this result. Although the salts have been grouped in the above table it is not to be supposed that a dilute solution like sea water contains all the ingredients thus arbitrarily combined. There must be considerable dissociation of molecules and as a first approximation it may be taken that of ten molecules of most of the components about nine (or in the case of magnesium sulphate five) have been separated into their ions, and that it is only during slow concentration as in a natural saline that the ions combine to produce the various salts in the proportions set out in the above table. One can look on sea water as a mixture of very dilute solutions of particular salts, each one of which after the lapse of sufficient time fills the whole space as if the other constituents did not exist, and this inter-diffusion accounts easily for the uniformity of composition in the sea water throughout the whole ocean, the only appreciable difference from point to point being the salinity or degree of concentration of the mixed solutions.

The origin of the salt of the sea was attributed by some authorities entirely to the washing out of salts from the land by rain and rivers and the gradual concentration by evaporation in the oceans. This hypothesis, however, does not accord with the theory of the development of the earth from the state of a sphere of molten rock, surrounded by an atmosphere of gaseous metals, by which the first-formed clouds of aqueous vapour must have been absorbed. The great similarity between the salts of the ocean and the gaseous products of volcanic eruptions at the present time, rich in chlorides and sulphates of all kinds, is a strong argument for the ocean having been salt from the beginning. Two other facts are totally opposed to the origin of all the salinity of the oceans from the concentration of the washings of the land. The proportions of the salts of river and sea water are quite different, as Julius Roth shows thus:—

	Carbonates	Sulphates	Chlorides
River water	80	13	7
Sea water	0.2	10	89

The salt of salt lakes which have been formed in the areas of internal drainage in the hearts of the continents by the evaporation of river water are entirely different in composition from those of the sea, as the existence of the numerous natron and bitter lakes shows. Magnesium sulphate amounts to 4.7% of the total salts of sea water according to Dittmar, but to 23.6% of the salts of the Caspian according to Lebedinzeff; in the ocean magnesium chloride amounts to 10.9% of the total salts, in the Caspian only to 4.5%; on the other hand calcium sulphate in the ocean amounts to 3.6%; in the Caspian to 6.9%. These two disparities make it extremely difficult, if not impossible, to view ocean water as merely an extract of the salts in the rocks.

The determination of salinity was formerly carried out by evaporating a weighed quantity of sea water to dryness and weighing the residue. This method was inexact. Sørensen and Knudsen after a careful investigation abandoned the old definition of salinity as the sum of all the dissolved solids in sea water and substituted the weight of the dissolved solids in 1,000 parts by weight of sea water on the assumption that all the bromine is replaced by its equivalent of chlorine, all the carbonate converted into oxide and the organic matter burnt. The advantage of the new definition lies in the fact that the estimation of the chlorine (or rather of the total halogen expressed as chlorine) is sufficient to determine the salinity. According to Knudsen the salinity is given in weight per thousand parts by the expression $S = 0.030 + 1.805C$, where S is the salinity and C the amount of total halogen in a sample. This definition was adopted by the International Council for the Study of the Sea in 1902.

Besides the determination of salinity by titration of the chlorides, the method of determination by the specific gravity of the sea water is still used. In the laboratory the specific gravity is determined in a pycnometer by actual weighing, and on board ship by the use of an areometer or hydrometer. In all areometer work it is necessary to ascertain the temperature of the water

sample under examination with great exactness, as the volume of the areometer as well as the specific gravity of the water varies with temperature. All determinations must accordingly be reduced to a standard temperature for comparison. Following the practice of J. Y. Buchanan on the "Challenger," it has been usual for British investigators to calculate specific gravities for sea water at 60° F compared with pure water at the maximum density point (39.2°) as unity. On the continent of Europe it has been more usual to take both at 17.5° C (63.5° F), which is expressed as

$$\frac{S_{17.5}}{17.5}$$

A careful investigation of the relation between the amount of chlorine, the total salinity and the specific gravity of sea water of different strengths including an entirely new determination of the thermal expansion of sea water was made by M. Knudsen, 1899; the results are published in his *Hydrographical Tables* in a convenient form for use (1901).

The temperature of maximum density of sea water of any specific gravity was determined by Knudsen, the temperature of maximum density is lower as the concentration of the sea water is greater, as is shown in the following table:—

Maximum Density Point of Sea Water of Different Salinities

Salinity per mille	0	10	20	30	35	40
Temperature θ° C	3.95°	1.86°	-0.31°	-2.47°	-3.52°	-4.54°
Density σθ	1.00000	1.00818	1.01607	1.02415	1.02822	1.03232

In this table density σθ signifies the specific gravity of the sea water in question at θ temperature.

Further Physical Properties of Sea Water.—The laws of physical chemistry relating to complex dilute solutions apply to sea water, and hence there is a definite relation between the osmotic pressure, freezing-point, vapour tension and boiling-point by which when one of these constants is given the others can be calculated.

Salinity per mille	10	20	30	35	40
Freezing-point (C)	-0.53	-1.07	-1.63	-1.91	-2.20
Osmotic pressure (atmospheres)	6.4	13.0	19.7	23.1	26.6
Elevation of boiling-point (C)	0.16	0.31	0.47	0.56	0.64
Reduction of vapour pressure (mm.)	4.2	8.5	13.0	15.2	17.6

The biologic importance of the osmotic pressure of sea water will be easily understood from the fact that a frog placed in sea water loses water by exosmosis and soon becomes 20% lighter than its original weight, while a true salt water fish suddenly transferred to fresh water gains water by endosmosis, swells up and quickly succumbs. The elevation of the boiling-point is of little practical importance, but the reduction of vapour pressure means that sea water evaporates more slowly than fresh water, and the more slowly the higher the salinity. The fact that sea water does evaporate more slowly than fresh water has been proved by the observations of Mazelle at Trieste and of Okada in Azino (Japan). Their experiments show that in similar conditions the evaporation of sea water amounts to from 70 to 91% of the evaporation of fresh water. G. Wüst calculates that in one year on an average 0.82 metre of water is evaporated over all the seas of the world; in the trade wind zone something like 1.10 metres and in high latitudes only 0.5 metre or less.

Transparency and Colour of Sea Water.—The optical properties of sea water are of direct importance in biology, as they affect the penetration of sunlight into the depths. The transparency of sea water has frequently been measured at sea by the simple experiment of sinking white-painted discs and noting the depth at which they become invisible. In the North sea north of the Dogger bank, for instance, the disc is visible in calm weather to a depth of from 20 to 30 metres, but in rough weather only to 10 metres. The greatest transparency hitherto reported is in the Sargasso sea, where Krümmel observed a 2 metre disc to depths of 66 metres, but in the cold currents of the north Atlantic and also in the equatorial current the depth of visibility was only from

20 to 30 metres. In the tropical Indian and Pacific oceans the depth of visibility increases to from 40 to 50 metres.

Spindler and Wrangell in the Black sea studied transparency by sinking an electric lamp; experiments have also been made by using photographic plates to find the greatest depths to which light penetrates. Fol and Sarasin detected the last traces of sunlight in the western Mediterranean at a depth of 370 metres, and Murray and Hjort observed that photographic plates, after an exposure of two hours at a depth of 1,500 metres in mid-Atlantic, had become dark. The chief cause of the different transparency is the varying quantity of mineral particles in suspension or of plankton. Schott gives the following as the result of measurements of transparency by means of a white disc at 23 stations in the deep ocean, where quantitative observations of the plankton under 1 square metre of surface were made at the same time.

	Volume of plankton	Depth of visibility	Colour
	ccm.	metres	
Mean of 11 stations poor in plankton	85	26	Blue
Mean of 12 stations rich in plankton	530	16	Green

The colour of ocean water far from land is an almost pure blue, and all the variations of tint towards green are the result of local disturbances, the usual cause being turbidity of some kind, and this in the high seas is almost always due to swarms of plankton. The colour of sea water as it is seen on board ship is most readily determined by comparison with the tints of Forel's xanthometer which consists of a series of glass tubes filled with a mixture of blue and yellow liquids in varying proportions. Observations with the xanthometer have shown that the purest blue (0.1 on Forel's scale) is found in the Sargasso sea, in the north Atlantic and in similarly situated tropical or subtropical regions in the Indian and Pacific oceans. The northern seas have an increasing tendency towards green, the Irminger sea showing 5.9 Forel, while in the North sea the water is usually a pure green (10-14 Forel), the western Mediterranean shows 5.9 Forel, but the eastern is as blue as the open ocean (0.2 Forel). A pure blue colour has been observed in the cold southern region, where the "Valdivia" found 0.2 Forel in 55° S. between 10° and 31° E., and even the water of the North sea has been observed at times to be intensely blue. Over shallows even the water of the tropical oceans is always green. There is no relationship between colour or transparency on the one side and the temperature or salinity on the other, but a distinct relationship between colour, transparency and plankton or mineral particles in suspension in the ocean. The most transparent water which is the most free from plankton is always the purest blue, while an increasing turbidity is usually associated with an increasing tint of green. The physical explanation for these facts, according to the investigations of K. Grien near Capri, is the selective absorption of light in water. In the following table the originally existing amount of light is supposed to equal 1,000.

Colours of the spectrum	Red	Yellow	Green	Blue	Violet
Wave lengths in μ	650	600	550	450	410
Depth 5 metres	3.7	2.5	250	450	866
" 20 "	0.03	1.2	5.8	277	666
" 50 "	0.002	0.03	2.2	201	200
" 100 "	..	0.001	0.03	5.5	10
" 200 "	0.004	0.04	1

At a depth of 50 metres red and yellow are wholly absorbed, while $\frac{200}{1,000}$ of the blue and violet rays of the original amount of light still exist. Blue is the natural colour of water over the greater depths and the colour seen by divers. Clear sea water looks blue from the surface because some of the non-absorbed rays are reflected, but if the water contains mineral substances or plankton the red and yellow rays may also be reflected and the colour of the water is green. Discoloration is always due to foreign sub-

stances. Brown or even blood-red stripes have been observed in the north Atlantic when swarms of the copepod *Calanus finmarchicus* were present; the brown alga *Trichodesmium erythraeum*, as its name suggests, can change the blue of the tropical seas to red; swarms of diatoms may produce olive-green patches in the ocean, while some other forms of minute life have at times been observed to give the colour of milk to large stretches of the ocean surface.

Other Properties.—On account of its salinity, sea water has a smaller capacity for heat than pure water. The specific heat diminishes as salinity increases, so that for 10 per mille salinity it is 0.968, for 35 per mille it is only 0.932, that of pure water being taken as unity. The internal friction or viscosity of sea water has been shown by E. Ruppini to increase with the salinity. Thus at 0° C the viscosity of sea water of 35 per mille salinity is 5.2% greater and at 25° C 4% greater than that of pure water at the same temperatures; in absolute units the viscosity of sea water at 25° C is only half as great as it is at 0° C.

The compressibility of sea water increases with decreasing temperature, salt content and pressure. The difficult calculation of the amount of compressibility has recently been carried out by W. Ekman, Bjerknes and Sandström. The following series from the Philippine trench shows the variations.

Depth (metres)	Temperature °F	Salinity ‰	Specific gravity	
			Without compression	With compression
0.	80.8	34.32	1.02220	1.02220
100.	76.6	34.86	1.02331	1.02376
1,000.	40.1	34.53	1.02730	1.03215
5,000.	34.7	34.68	1.02777	1.05107
10,000.	36.7	34.68	1.02768	1.07123

One litre of water at this last depth therefore weighs not 1027.68 grams but actually 1071.23 grams. If the whole mass of water in the ocean were relieved from pressure its volume would expand from 1,369 million cub. km. to 1,381 million cub. km., which, for a surface of 361 million sq. km., means an increased depth of 32 metres.

THE GASES OF SEA WATER

The water of the ocean, like any other liquid, absorbs a certain amount of the gases with which it is in contact, and thus sea water contains dissolved oxygen (O₂), nitrogen (N₂), and carbonic acid (CO₂) absorbed from the atmosphere. Great quantities of CO₂ are, in addition, present in carbonates. It is important for the sea organisms, particularly for fish which breathe through gills, that the absorbed air, although the amount is very small, contains more oxygen per cent than that of the atmosphere. At the surface one litre of sea water of 35‰ salinity and at a temperature of 50° F contains normally 18.7 c.c. of gas, consisting of 6.4 c.c. of oxygen, 12.0 c.c. of nitrogen and 0.3 c.c. of carbonic acid gas. These 6.4 c.c. of oxygen are 34% of the whole absorbed air, while oxygen forms only 21% of the atmosphere. The quantity of oxygen usually increases with decreasing temperature and decreasing salt content; it is also greater at the surface than in the depths, where the oxygen is consumed by the breathing of organisms and cannot be directly replaced.

In the last 20 or 30 years the distribution of oxygen in time and place, in the Atlantic and European enclosed seas, at least, has been fairly thoroughly examined. It has been found that in the Tropics, between 20° S. and 20° N., the water between 100 and 1,000 metres deep is very poor in oxygen, having generally only 2 or 3 c.c. per litre, but in the high polar latitudes the water contains 7 or 8 c.c. of oxygen per litre at the surface and even in the depths. In these high latitudes the water evidently sinks at times from the surface to the sea floor and maintains the oxygen at the bottom. This polar ground water flows away towards the Equator and so the water at the bottom of tropical seas has enough oxygen to enable organisms to exist. Where this vertical sinking of the surface water does not occur, as in the Baltic, the bottom water is very poor in oxygen; often oxygen is absent, e.g., north of

FIG. 2

Gothland, and animal life is then limited. In the Black sea the deep water is always and everywhere free from oxygen, and organisms are quite absent. On the other hand, one observes in the upper, sun-penetrated layers an abundance of oxygen, when in spring the plankton plants develop and produce oxygen through the so-called assimilation process. Where oxygen is scarce or absent there is generally a marked increase of CO_2 , e.g., on the floor of some Baltic hollows. This increase in the amount of CO_2 up to 12 times the normal amount, is caused by slow accumulation in the absence of renewal of the water and by the breathing of the sea animals; the water in these hollows is thus in the end poisoned. In contrast with the Baltic the North sea depths are sufficiently supplied with oxygen, and there is no marked increase in carbonic acid. For these reasons conditions are much more favourable for fish in the North sea than in the Baltic.

The gaseous, absorbed nitrogen plays no part here; its significance arises from the fact that nitrogen compounds have a nutritive value for plants, as on dry land. It has already been pointed out that in addition to carbonic acid gas, there is a large amount of CO_2 present in the dissolved carbonates. The greater part of the CO_2 occurs as carbonate and bicarbonate.

In the open ocean the alkali proportion of the salt content is set out in the formula

$$A \text{ (alkalinity)} = 0.77 S \text{ (salinity)}$$

where S is in ‰ and A in c.c. per litre. In this case, where the salt content is 35‰ the average alkalinity is 27 c.c. But great deviations appear, especially a great increase near coasts, where rivers bring down a large amount of carbonate.

Since 1851 it has been known that all sea water has an alkaline reaction. Absolutely pure water, which does not exist naturally, is neutral, it contains an equal amount of hydrogen ions and hydroxyl ions; it does not conduct an electric current and is neither alkaline nor acid. In sea water a considerable part of the water is resolved into the two components, (1) the positive hydrogen ion (H^+), and (2) the negative hydroxyl ion (OH^-), because weak acids, such as carbonic acid, and their salts in aqueous solution are subject to hydrolytic dissociation. The estimation of the hydrogen ions is used as a means of measuring the alkaline reaction of sea water, which depends both on the amount of free CO_2 and on the alkalinity discussed above. This hydrogen ion concentration of the sea varies around 10^{-8} grams per litre. All these factors have fixed relations to one another.

DISTRIBUTION OF SALINITY

In each of the three oceans there are two maxima of salinity of the surface water—one in the north, the other in the south

tropical belt, separated by a zone of minimum salinity in the equatorial region, and giving place poleward to regions of still lower salinity. The three oceans differ somewhat between themselves. The north Atlantic maximum is the highest with water of 37.9 per mille salinity; the maximum in the south Atlantic is 37.4; in the north Indian ocean, 36.7; the south Indian ocean, 36.4; the south Pacific, 36.9; and the north Pacific has the lowest maximum of all, only 35.7. The comparatively fresh equatorial belt of water has a salinity of 35.0 to 34.0 in the Atlantic and in the Indian ocean, 34.5 in the western and 33.5 in the eastern Pacific. Taking each of the oceans as a whole, the Atlantic has the highest general surface salinity with 35.37.

The salinity of enclosed seas naturally varies much more than that of the open ocean. The saltiest include the eastern Mediterranean with 39.5 per mille, the Red sea with 41 to 42 per mille in the Gulf of Suez, and the Persian gulf with 40 near Bushire. The fresher enclosed seas include the Malay and the East Asiatic fringing seas with 30 to 34.5 per mille, the Gulf of St. Lawrence with 30 to 31, the North sea with 35 north of the Dogger bank, diminishing to 32 further south, and the Baltic, which freshens rapidly from between 25 to 31 in the Skagerak to 7 or 8 eastward of Bornholm and to practically fresh water at the heads of the Gulfs of Bothnia and Finland. The Arctic sea presents a great contrast between the salinity of the surface of the ice-free Norwegian sea with 35 to 35.4, and that of the central Polar basin, which is dominated by river water and melted ice, and has a salinity less than 25 per mille in most parts.

The causes of difference of surface salinity are mainly meteorological. The belt of equatorial minimum salinity corresponds with the excessively rainy belt of calms and of the equatorial counter-current, the salinity diminishing towards the east. The tropical maxima of salinity on the poleward side of the trade-winds coincide with the regions of minimum rainfall, high temperature, strong trade-winds and consequently of maximum evaporation. Evaporation is naturally greatest in the enclosed seas of the nearly rainless subtropical zone such as the Mediterranean and Red sea. Where the evaporation is at a minimum, the inflow of rivers from a large continental area and the precipitation from the atmosphere at a maximum, there is necessarily the greatest dilution of the sea water, the Baltic and the Arctic seas being conspicuous examples.

The salt content of the sea water in the depths of the oceans has been investigated with certainty only during the last 10 or 20 years. While the variation at the surface is somewhere between 30 and 40‰, the variation at depths of more than 200 metres lies only between 35.5‰ and 34.5‰. These variations are there occa-

sioned not by meteorological phenomena, but by the currents of the deep sea. If we study the Atlantic, which is best known (fig. 2), we see that there is a great difference between the part in the northern hemisphere and that in the southern. In north latitudes the salt content diminishes steadily with the depth from 37 to 34.8‰ but in south latitudes the diminution proceeds only to a depth of 800 or 1,000 metres, where a first minimum of 34.3‰ is reached. From 800 metres or 1,000 metres to 2,000 or 3,000 metres the salt content increases to 34.9‰ in order to decrease from this layer again down to the sea floor, where a second minimum of 34.6‰ is observed. The particulars of the course of the isohalines or lines of equal salinity are explained best through looking at the deep currents along the arrow lines in the figure. In high south latitudes the heavy water, poor in salt, sinks from the surface into the depths and moves northward right over the Equator into the northern hemisphere at a moderate depth of from 600–1,000 metres as the so-called Intermediate Current or *Zwischenstrom*. In the northern mid-latitudes the salty, heavy water sinks from the surface into the depths and moves, at a depth between 1,000 and 3,000 metres, towards the southern hemisphere as the Depth current or *Tiefenstrom*. Finally at a still deeper level, on the ocean floor, the water moves from the southern to the northern hemisphere (the Floor current or *Bodenstrom*). Thus one finds currents with very different origins and varying salt content moving in various directions resulting from a combination of both vertical and horizontal movements. This scheme of the divisions of salt content and movement of water applies also to the Indian sea depths, and, fundamentally at least, to the Pacific. Most important for the origin of these movements is the fact that round the earth in the neighbourhood of Antarctica are present immense masses of water of high specific gravity which flow away northward at the surface of the sea and which then, somewhere around Lat. 50° S., sink towards the depths as the Intermediate current or *Zwischenstrom*. Without this immense south polar sea the properties of the deep sea water would be very different; the north polar seas, shut off from the south by ridges, can send forth no such great streams.

In general, the salt content of the depths of the great oceans is less than that of the surface; it is only the manner and rate of the decrease that is different in northern and in southern latitudes. In addition the polar seas have another factor of vertical distribution of salt content. In the icy seas, down to a depth of 100 or 200 metres, as a result of freezing, the water is very cold but poor in salt; under this, from 200 to 1,000 metres, is a layer of warmer, saltier water; from there to the bottom the temperature diminishes, but only a very little, and the salt content remains almost unaltered (fig. 2). The following table combines the latest figures for salt-content and temperature at five latitudes along meridian 30° W.

Salinity ‰					
Depths (metres)	South			North	
	60°	30°	0°	30°	60°
0	33.96	36.07	35.20	36.82	35.30
100	34.42	36.03	35.65	36.75	35.20

In a few enclosed seas—differing from the ocean—the salt content increases with the depth, e.g., in the Baltic and Black seas, because salty water flows into the seas along the floor from the North and Mediterranean seas respectively; the result is that in the middle of the Baltic, near Gothland, the salt content at the surface is only 6 or 7‰ while from a depth of 100 metres it rises to 11 or 13‰.

Temperature of the Oceans.—The temperature of the surface of the sea is obtained from samples dipped by a bucket. The measurement of temperature in the depths involves stopping the ship and employing thermometers of special construction. The best instrument and the one in general use to-day is the outflow or reversing thermometer, first introduced by Aimé in the Mediterranean in 1841–45, but greatly improved and simplified by Negretti and Zambra, London, and Richter Wiese, Berlin. The principle is to have a constriction in the tube above the bulb so proportioned that when the instrument is upright it acts in every way as an ordinary mercurial thermometer but when it is inverted the thread of mercury breaks at the constriction. Magnaghi introduced a convenient method of inverting the thermometer by means of a propeller actuated on beginning to heave in the line; greater precision and certainty are obtained by using a lever actuated by a weight slipped down the line to cause the reversal. All thermometers sunk into deep water must be protected against the enormous pressure to which they are exposed.

The warming of the ocean is due practically to solar radiation alone; such heat as may be received from the interior of the earth can only produce a small effect and is fairly uniformly distributed. On account of the high specific heat and of the turbulence of sea-water the diurnal range of temperature at the surface is very small. According to A. Buchan's discussion of the two-hourly observations on the "Challenger" the total range between the daily maximum and minimum in the warmer seas is between 0.7° and 0.8° F, and for the colder seas still less (0.2° F), compared with 3.2° F in the overlying air. The maximum usually occurs between 1 and 2.30 P.M., the minimum shortly before sunrise. The temperature of the surface water is generally a little higher than that of the overlying air, the daily average difference being about 0.6° F, varying from 0.9° lower at 1 P.M. to 1.6° higher at 1 A.M. There are few observations available for ascertaining the depth to which warmth from the sun penetrates in the ocean. The investigations of Aimé in 1845 and Hensen in 1889 indicate that the amount of cloud has a great effect. Aimé showed that on a calm, bright day in the Mediterranean the temperature rose 0.1° C between the early morning and noon at a depth of about 20 metres. The penetration of warmth from the surface is effected by direct radiation, by convection by particles rendered dense by evaporation increasing salinity, and through the turbulence of movement in the upper layers. After a storm the whole of the water in the North sea assumes a homothermic condition, i.e., the temperature is the same from surface to bottom, and this occurs not only south of the Dogger bank, where the condition is normal, but also, though less frequently, in the deeper water farther north. Similar effects are produced in narrow waters by the action of tidal currents, and the influence of a steady wind blowing on or off-shore has a powerful effect in mixing the water.

The warmest parts of the Indian ocean and Western Pacific have a mean annual temperature of 82° to 84° F, but such high temperatures are seldom found in the tropical Atlantic. In the Indian ocean between 15° N and 5° S. the surface temperature in May averages 84° to 86° F, and in the Bay of Bengal the temperature is 86°, and no part of the Atlantic has so high a monthly mean temperature at any season. G. Schott's investigations show that the annual range of surface temperature in the open ocean is greatest in 40° N., with 18.4° F, and in 30° S., with 9.2° F; on the contrary, near the equator it is less, only 4° F in 10° N., and in high latitudes it is also small, 5.2° F in 50° S. The figures quoted above are differences between the average surface temperatures of the warmest and of the coldest month. As to the absolute extremes of surface temperature, Sir John Murray points out that 90° F frequently occurs in the western part of

the tropical Pacific, while among seas the Persian gulf in summer months reaches 96° F, only 2° under blood-heat, and the Red sea follows closely with a maximum of 94° . The greatest change of temperature at any place has been recorded to the north-east of Japan with a minimum of 27° F and a maximum of 83° . In those localities, however, it is not the same water which varies in temperature with the season, but the water of different warm and cold currents which periodically occupy the same locality as they advance and retreat. The zones of surface temperature are arranged roughly parallel to the equator, especially in the southern hemisphere. Between 40° N. and 40° S. the currents produce a considerable rearrangement of this order. The arrangement of the isotherms thus affords a basis for valuable deductions as to the direction of ocean currents.

Krümmel's calculation gives the proportional areas at a high temperature as follows:—

Percentage of Ocean Surface

With temperature	Atlantic	Indian	Pacific
Over 77° F (25° C).	22.4	38.0	40.1
Over 68° F (20° C).	50.1	51.7	58.4

The vertical distribution of temperature in the open ocean is better known than that of salinity. Such information has already been given above (p. 689) in the table of salinity. The regional differences of temperature at like depths become less as the depth increases. Thus at 300 fathoms or roughly 500 metres greater differences than 22° F hardly ever occur between 60° N. and 60° S., in 800 fathoms or 1,500 metres the differences are less than 15° , and in 1,500 fathoms or 3,000 metres less than 7° . Even in the tropics the high temperature of the surface is confined to a very shallow layer; thus in the Central Pacific where the surface temperature is 82° F the temperature at 200 metres is only 52° F. The whole ocean must thus form but a cold dwelling-place for the organisms of the deep sea. Sir John Murray calculates that at least 80% of the water in the ocean has a temperature always less than 40° F, and a recent calculation by Krümmel gave in fact a mean temperature of 39° F for the whole ocean.

The vertical distribution of temperature in mid-ocean in the greater depths, i.e., depths of more than 200 metres or 100 fathoms, shows first a peculiar situation under the equator and secondly a great difference between the same latitudes north and south. If we use the above table of five points in the Atlantic we find that the water, from a depth of 100 metres to one of at least 600 metres, is colder under the equator than at lat. 30° S. and lat. 30° N., e.g., the water, 200 metres down at the equator, is 9° F colder than at the Bermudas (54.7° and 63.7° respectively). One gathers from this that even at these moderate depths much water in the equatorial zone is rising from the underlying depths, while in mid-latitudes it is sinking. Particularly is this the case in the Sargasso sea between the Azores and the Bermudas. This region shows relatively the highest temperature even down to depths of 2,000 or 3,000 metres; it is considered as the starting point of the North Hemisphere Depth Current or *Tiefenstrom*. (See fig. 2.) The North Atlantic is on the whole much warmer than the South Atlantic; this is seen by a comparison of the temperatures at equal depths at 30° lat. N. or S., and still more at 60° lat. In the region 60° N. and 30° W., south of Iceland, one does not find polar or arctic temperatures in the depths, but at 60° S. and 30° W., near South Georgia, they are well marked. Similarly in the Indian and Pacific oceans, the water at a depth of from 100 to 600 metres, near the equator is colder than that north and south of it; and in both these oceans the water at greater depths in middle latitudes is colder in the Southern than in the Northern hemispheres, depth for depth. Everywhere, as in the case of salt content, one finds the northward-reaching influence of the huge, cold, antarctic body of water. The Indian ocean has no connection with the north polar region, the Pacific has ice in quantity only in the Sea of Okhotsk and parts of the Bering sea, and it is separated from the Arctic basin by the narrow Bering strait. But in the depths the Atlantic

is also well sheltered from the north polar water by great submarine ridges. Thus it happens that the world ocean is much colder in southern than in northern latitudes.

Generally, the temperature, like the salt content, decreases with the depth. In polar waters this is not the case; here the temperature increases below the surface layers, which had been cooled by ice and cold air to 29.5° F, until at 1,000 metres it is somewhere around 32° or 33° F, and diminishes slowly thence to the bottom. Therefore the arrangement of the temperature is usually *anatherm* (*ἀνά* above *θερμὸς* warm) but in the polar seas it is *katatherm* (*κάτά* under) or *dichotherm* (*διχα* apart). There are also deep regions described as *homotherm*, where from the level of the barrier to the bottom, the temperature remains uniform. Thus south-west of Cape Province (S. Africa) in the Cape Trough, the temperature decreases continuously until it reaches 33.3° F in the greatest depths, while north of the Wal-fisch ridge and east of the south Atlantic rise in the so-called Congo Deep the temperature remains uniform at 36.4° F from 3,500 metres down to the bottom. Thus in the Central American sea below 1,700 metres, the depth on the bar, no water is found at a temperature lower than that prevailing in the open ocean at that depth, viz., 39.6° F, not even at the bottom of the great Bartlett Deep in 6,200 metres. Such homothermic masses of water are characteristic of all deep enclosed seas. Thus in the Malay sea the various basins are homothermic below the depth of the rim, at the temperature prevailing at that depth in the open ocean. In other enclosed seas shut off from the ocean by a very shallow sill the rule holds good that the homothermic water below the level of the sill is at the lowest temperature reached by the surface water in the coldest season of the year, provided always that the stratification of salinity is such as to permit of convection being set up. To this group belongs the Arctic sea. The Mediterranean sea also belongs to this group; its various deep basins are nearly homothermic (at the winter surface temperature) below the level of their respective sills.

An undercurrent flows out from the Red sea through the Strait of Bab-el-Mandeb, and from the Mediterranean through the Strait of Gibraltar, raising the salinity as well as the temperature of the part of the ocean outside the gates of the respective seas. The action of the Red sea water affects the whole of the Gulf of Aden and Arabian sea, raising the temperature at the depth of 1,000 metres to 52° or 53° F or 9° F higher than the water of the Bay of Bengal at the same depth. The effect of the Mediterranean water in the North Atlantic does not require such large figures to express it, but is extraordinarily far-reaching. There are clear traces of the warm and salty Mediterranean water northward as far as Ireland, westward as far as the Azores and southward as far as the Canaries, at a depth of from 1,000 to 1,600 metres. In shallow seas as the North sea and the British fringing seas, where tidal currents run strong, there is a general mixing together of the surface and deeper water, thus making the arrangement of vertical temperature anathermic in summer and katathermic in winter, while at the transitional periods in spring and autumn it is practically homothermic. Thus at Station E₂ of the international series at the mouth of the English channel in $49^{\circ} 27' N.$, $4^{\circ} 42' W.$, the following distribution of temperature F has been observed by Matthews:—

	Aug., 1904	Nov., 1904	Feb., 1905	May, 1905
Surface	63.7°	56.2°	50.7°	51.3°
30 metres	55.5	56.5	50.8	50.5
100 metres	55.4	56.5	50.8	50.5

It is noticeable that there is a marked vertical temperature gradient only at the end of summer when a warm surface layer is formed, though in Aug. 1904 that was only 14 metres thick. The heat content of the water column, at Station E₂ and other places where investigations have occurred in great detail, has been shown by Harvey to vary greatly from year to year.

Sea Ice.—The freezing-point of sea water is lower as the salinity increases and normal sea water of 35 per mille salinity freezes at 28.6° F. Experience shows that sea water can be cooled

considerably below the freezing-point without freezing if there is no ice or snow in contact with it. The dissolved salts are excluded in the process in a regular order according to temperature. As very low air temperatures seldom occur, freshly formed sea ice always has a salt content of from 12 to 18‰ if the original salt content of the water was 34‰, and the sea ice is therefore not suitable as a source of drinking water. In general the salt is returned to the lower unfrozen water, but during a continued hard frost it may appear as crystals on the surface; these crystals are known to polar explorers by the Siberian name of *rassol*. Ice is a very poor conductor of heat and accordingly protects the surface of the water beneath from rapid cooling; hence new-formed pancake ice does not increase excessively in thickness in one winter, and even in the centre of the Arctic basin the ice-covering only amounts to 2 or at most 3 metres in the course of a year, while in the Antarctic regions the season's growth is only half as great; in the latter also the accumulated snow is an important factor in the thickness of the ice, and snow is an even worse conductor of heat. The influence of wind and tide breaks up the frozen surface of the sea, and sheets yielding to the pressures slide over or under one another and are worked together into a hummocky ice-pack, the irregularities on the surface of which, caused by repeated fractures and collisions, may be from 3 to 7 metres high. Such formations termed *toross* by the Russians, may extend under water, according to Makaroff's investigations, to at least an equal depth. Such old sea ice, when prevented from escaping, forms the palaeocrystic sea of Nares; but, as a rule, it is carried southward in the East Greenland and Labrador currents, and melted in the warmer seas of lower latitudes. In the Southern Hemisphere the ice-pack forms a nearly continuous fence around the Antarctic continent. Pack ice forms regularly in the inner part of the Baltic every winter, but not in the Norwegian fjords. Even in the Mediterranean, sea ice is formed annually, in the northern part of the Black sea, and more rarely in the Gulf of Salonika and at the head of the Adriatic off Trieste. Hudson bay is blocked by ice for the greater part of the year, and the Gulf of St. Lawrence is blocked every winter. Ice also clothes the continental shores of the northern fringing seas of eastern Asia. In addition to sea ice, icebergs which are of land origin occur at sea. In the north, icebergs break off, as a rule, from the ends of the great glaciers of Greenland, and in the far south from the edge of the great Antarctic ice-barriers. The latter often give birth to prodigious icebergs and ice islands, which are carried northward by ocean currents nearly as far as the tropical zone, before they melt. The Antarctic icebergs are of tabular form and much larger than those of Greenland, but in either case an iceberg rising to 70 metres above sea-level is uncommon and one exceeding 100 metres is very rare. The Greenland icebergs are carried by the Labrador current across the great banks of Newfoundland, where they are often very numerous in the months from March to August, when they constitute a danger to shipping as far south as 40° N. No icebergs occur in the North Pacific and none has ever been reported nearer the coasts of Europe than off the Orkney islands, and there only once in 1836.

Oceanic Circulation.—Although observations on marine currents were made near land or between islands even in antiquity, accurate observations on the high seas have only been possible since chronometers furnished a practicable method of determining longitude, *i.e.*, from the time of Cook, the circumnavigator. The difference between the position as determined astronomically and by dead-reckoning gives an excellent idea of the general direction and velocity of the surface-currents. The first comprehensive study of the currents of the Atlantic was that carried out by James Rennell (1790–1830), and since that time Findlay in his *Directories*, Heinrich Berghaus, Maury and the officials of the various hydrographic departments have produced increasingly accurate descriptions of the currents of the whole ocean. Direct observations of currents in the open deep sea are difficult, but Americans have measured directly from anchored ships the Gulf Stream currents in the Caribbean sea. Similarly, for the whole South Atlantic region, the German survey ship "Meteor" (1925–27) was anchored to measure the currents at all depths with

Ekman's current-meter. One of the indirect methods of investigating currents is by taking account of the initial temperature of the current and following it by the thermometer throughout its course. Benjamin Franklin (1775) and Charles Blagden (1781), by means of numerous observations of temperature made on board the packets plying on the Atlantic passage, determined the boundaries and seasonal variations of Gulf Stream and Labrador current. In the northern European seas, salinity often proves a sharper criterion of the boundaries than temperature. Evidence drawn from driftwood, wrecks or special drift bottles is less distinct but still interesting and often useful. Icebergs and plankton also serve as indicators of the trend of currents.

Ocean surface-currents depend in general on the prevailing winds, the configuration of the coast and its submarine approaches. The trade-wind regions correspond pretty closely with westward-flowing currents, while in the equatorial calm belts there are eastward-running counter-currents. In a similar manner the Brazil, the Agulhas and the East Australian currents originate from the drift of the south-east trades, and the Japan current arises from the north-east trade drift. In the region of the westerly winds on the poleward side of 40° N. and S. the currents again flow generally eastward.

The general accordance of wind and surface-currents is so obvious that it was fully recognized by seafaring men in the time of the first circumnavigators. Modern investigations have shown, however, that the relationship is by no means simple. We must remember that the ocean is a continuous sheet of water of a certain depth; if a single water particle is set in motion, the whole ocean must respond, as Varenus pointed out in 1650. Only a complete system of circulation can exist in the ocean, and horizontal and vertical movements of water are definitely related to one another. Modern oceanographic investigations of temperature and salt content in the depths, as well as dynamic analyses show that surface water where two surface-currents come together, sinks into the depths (fig. 3), but that where two surface-currents diverge water from the depths rises (fig. 4). The Sargasso sea is an important convergence region. A divergence region lies southward of the Cape Verde islands.

Many hitherto enigmatic phenomena are explained by such convergence and divergence lines; *e.g.*, long ribbons of foam, drifting bodies in long lines, ripples, and small patches of cold water in the midst of warm water.

We also know that the surface-currents have only a very small depth in consequence of the combined action of earth rotation and eddying friction. Following a suggestion by F. Nansen, W. Ekman in 1906 pointed out that current at the absolute surface is deflected 45° to the right (Northern Hemisphere), or 45° to the left (Southern Hemisphere) of the wind direction; the north-east trades therefore produce not a south-westerly but a westerly current, a fact established by observation. Analogous deflections are characteristic for all depths, and already at a depth of 100–150–200 metres the direction is generally opposite to that at the surface as fig. 5 shows.

The depth at which the current practically ends is called the friction-depth; it is dependent on the velocity at the surface and on the latitude. The eddying friction which reduces the velocity of water below the surface, on the other hand causes surface movements to become rapidly movements beneath the surface.

W. Ekman showed further that a pure wind-drift current when towards the coast, causes a heaping up of the water, and if away from the land, a welling up of deep water. The latter phenomenon is most clearly shown by the stripes of cold water along coasts of

FIG. 3

FIG. 4

north-west and south-west Africa and the west coasts of North and South America. Upwelling coastal water is coldest close to the shore. The heaping up of surface water upon the coast, gives rise in the depths to a counter-current from the coast. This bottom counter-current maintains its level, is also subject to deflection on account of the rotation of the earth, and has a large share in securing vertical circulation and ventilation of the ocean.

There are also currents produced by variations in the density of water (p. 688). Ekman calls these convection streams; they depend ultimately on the varying rates of cooling, warming or evaporation of water at various places. The consequent variations in density produce variations in pressure at one and the same depth; the heavier water endeavours to flow under the lighter, and the lighter strives to spread itself out over the heavier. The great horizontal compensatory ocean streams between the Northern and Southern Hemispheres are to be explained most probably by differences of pressure; but we have also density or convection streams on the surface of the ocean, associated with or separate from the wind or drift currents. The so-called "Atlantic Current" on the west coast of Europe—a so-called continuation of the Gulf Stream—is only in small part a wind drift. It is principally the result of a density current, for in the Norway sea the density is very high while between lat. 40° and 50° it is low. In particular cases, in straits linking seas of differently constituted water, the density or convection currents develop in such a way that a surface-current goes in one direction, then appears a boundary zone, where the velocity is zero, and under this there is a deep current flowing in a direction contrary to that of the surface-current.

The very dense water of the Red sea and the Mediterranean makes the column of water salter and heavier and the level lower than in the ocean beyond the straits. Hence a strong surface-current sets inwards through the straits of Bab-el-Mandeb and Gibraltar, while an undercurrent flows outwards, raising the temperature and salinity of the ocean for a long distance beyond the straits. Through the Bosphorus and Dardanelles at the entrance of the Black sea, and through the sound and belts at the entrance of the Baltic, streams of fresh surface water flow outwards to the salter Mediterranean and North sea, while salter water enters in each case as an undercurrent. Wind and tide greatly alter the strength of these currents.

Strongly marked differences in density are produced by the melting of sea ice. O. Pettersson has made a careful study of ice melting as a motive power in oceanic circulation, and points out that it acts in two ways; on the surface it produces dilution of the water, forming a fresh layer and causing an outflow seaward of surface water with very low salinity; towards the deep water it produces a strong cooling effect, leading to increase of density and sinking of the chilled layers. Similarly, warmer deep water is attracted polewards to the region of the frozen seas as a result of the flowing away thence of cold surface water. This helps to explain the peculiar distribution of temperature and salt content around the poles.

Modern oceanography has found means to calculate quantitatively the circulatory movements produced by wind and the distribution of temperature and salinity, not only at the surface but in deep water. The methods, first suggested by H. Mohn and subsequently elaborated by V. Bjerknes, Sandstrom, Helland-Hansen and others, have been very usefully applied in many cases by means of so-called dynamical sections, but they should be supplemented by direct observations of currents and of the fundamental processes and conditions underlying them. The determination of the exact relationship of cause and effect in the origin of ocean currents is a matter of great practical importance. The researches of Pettersson, Meinardus, H. N. Dickson and others

leave no doubt, for example, that the variations in the intensity of the Gulf Stream, whether these be measured by the change in the strength of the current or in the heat stored in the water, produce great variations in the character of the weather of northern Europe.

The connection between variations of current strength and the conditions of existence and distribution of plankton are no less important, especially as they act directly or indirectly on the life-conditions of food fishes.

OCEAN GROVE, a summer resort of Monmouth county, New Jersey, U.S.A., on the Atlantic coast, adjoining Asbury Park on the south. It is served by the Central of New Jersey, the New York and Long Branch and the Pennsylvania railways and motor-coach lines. The resident population in 1928 was about 3,000. There are 40 or more hotels, many private cottages and a mile of "board walk" along the sea front. Ocean Grove was founded in 1869 by the Ocean Grove Camp-Meeting Association of the Methodist Episcopal Church, as a place for religious worship, rest and recreation, free from all kinds of undesirable amusements, and it keeps much of its original character. It is governed under a corporation charter which authorizes restrictions in the leases.

OCEANIA, a geographical area extending from Australia, in the west, to the most easterly islands of Polynesia, in the east, and from New Zealand, in the south, to Micronesia and the Sandwich islands, in the north. Ethnologically the area is divisible into six principal regions (*q.v.*): Australia; Tasmania; Melanesia, a group of islands extending from Fiji, in the south-east, to New Guinea, in the west; New Guinea, which, however, is a geographical rather than an ethnological unit, for the eastern and north-eastern coastal regions are Melanesian, while the west really falls under Indonesia; Polynesia, an island area of considerable racial and cultural uniformity, comprising the greater part of the Pacific; Micronesia, an island area comprising that part of the Pacific which lies between New Guinea, Polynesia and the Philippines.

Racial History.—There is little doubt that man first entered this area from the west, and subsequent migrations have all had an easterly, or, in the case of Australia, a southerly trend. The problem of dissecting out the racial components of the peoples on the eastern and southern periphery is, therefore, comparatively simple. Furthermore, the uniformity, both of physical type and culture, and evidence of a more or less historical kind, show that the Polynesian area is of comparatively recent occupation, even allowing for more than one principal set of migrations. But in New Guinea and Melanesia, the principal gateways into Oceania, conditions are more complex, and the racial history of this area has been only tentatively elucidated. Australia, again, shows considerable physical and cultural uniformity with many variations, but the existence of varieties of the Papuan type of man in Tasmania, with a very primitive culture, suggests that man entered and crossed the length of Australia at an extremely early date.

Principal Groups.—The six principal divisions of this region, Australia, Tasmania, Melanesia, New Guinea, Polynesia and Micronesia, can be fairly readily distinguished from one another, both racially and culturally, though, in the case of New Guinea, there is not that racial and cultural uniformity which characterizes each of the other areas. Apart from New Guinea, with its great diversity of race and culture, some general characterization of culture as well as race can be made of each of the other areas. Language, for example, will readily separate Australia, and in all probability Tasmania, from the group Melanesia, Polynesia and Micronesia. The speech of these three areas, together with the Melanesian and Indonesian part of New Guinea, is clearly referable to one family, the Austronesian (*q.v.*), extending from part of India and Burma, through Malaya and Indonesia to the extremities of Polynesia. But while the Polynesian languages may be described as dialects of one language, there is considerably more diversity within the Melanesian sub-division of this family.

This Austronesian speech is associated with a distinctly higher culture, particularly in Polynesia and Micronesia, the Melanesians being in some respects intermediate between these groups and the Papuans of New Guinea, though among Papuans there is great variety of culture, the result, no doubt, of various degrees of blending of immigrant cultures with perhaps more than one indigenous culture brought into New Guinea and Melanesia by the original Papuans.

The Australians, culturally as well as physically, betray a marked contrast, not only with the Austronesian-speaking peoples of Oceania, but also with the Papuans of New Guinea. Horticulture, well-developed throughout the rest of the area, excepting Tasmania, is entirely absent, and the economic life is, consequently, of a very low order. Nevertheless, an elaborate social

organization and ceremonial life and considerable variation in such stable aspects of culture as the disposal of the dead, survive in Australia.

Mode of Life.—The Australians and Tasmanians, being hunters and collectors, are necessarily nomadic, though within more or less well-developed tribal areas. Their most important possessions are their hunting weapons, spears, boomerangs and tools rudely chipped out of stone. The aridity of most of Australia during the greater part of the year, and the very short period during which nature provides abundant food, cause most of the non-economic activities of the Australians to be concentrated in the brief period of spring, when magico-religious rites with the object of increasing the food supply are performed, initiations are conducted, and, in fact, most of the tribal, in contrast with family, activities take place.

In the rest of the area, with its basis of horticulture, the economic struggle is not so keen, and the population is a settled one, except for a few nomadic or semi-nomadic peoples in New Guinea. Diet is mainly vegetarian, taro, yams, bread-fruit, sweet potato, coco-nuts, sago and bananas being the principal foods. In island and coastal regions fish is largely consumed, and almost everywhere pigs are reared and reserved for consumption on occasions of importance, such as marriage festivals and mortuary feasts. Although cannibalism is common, the eating of human flesh is usually a ceremonial act of revenge, or associated with mortuary or other rites. Canoes capable of long sea voyages are constructed, principally in the island areas. Double canoes, and outrigger canoes of various patterns and, formerly, double canoes which only survive at the present day in a limited part of New Guinea, are the commonest, the larger ones being provided with sails. While intercommunication is much hampered by warfare, goods are traded over considerable distances, and in many areas well-developed systems of currency occur.

Social Organization.—One feature of social organization appears to be common to the whole of this area, namely, the systematic non-genealogical use of relationship terms, generally known as the classificatory system. If we select any person in a village and enquire as to his relationship to others in the village, he will rarely be at a loss, for everyone is likely to be a mother, or a brother, an uncle or a father-in-law, etc., in this classificatory sense, and such relationships will be found to hold to a large number of persons in other more distant villages. Moreover, these classificatory relationships are important determinants of conduct, many rights and duties being dependent on relationship, though when the relationship is very distant in the classificatory sense they are hardly distinguishable. One of the most important functions of this relationship system lies in the regulation of marriage, those lying in certain relationships being prohibited from marriage, while in some cases only those persons who can establish a given relationship between themselves are allowed to marry. Marriage, however, is generally regulated, at least in part, by the clan (*q.v.*) which is usually, throughout this area, the most important social unit. Particularly in Australia, Melanesia and New Guinea, and to a slightly less extent in Polynesia, is the clan a fundamental unit of the social structure. Membership of the clan is determined by descent through the father or the mother, both varieties being common, and marriage is prohibited within the clan. As a rule, the clan is also totemic (*see TOTEMISM*), this totemic aspect being peculiarly important in Australia, where totemic rites form a large part of the ceremonial life of the natives. In parts of the area, especially Australia and Melanesia, the clans are grouped into two exogamous moieties (*see DUAL ORGANIZATION*), and there is some evidence which suggests that a dual organization once extended over most of the area or occurred among their ancestors before their migrations into Oceania.

Political Organization.—In Australia and parts of Melanesia, age appears to be an important qualification of leadership, councils of elders deciding matters of tribal importance. In parts of Melanesia there is little vested authority, a more or less communistic system prevailing, while in other parts, authority depends on the acquirement of prestige derived from the holding of feasts, or the acquisition of wealth. Hereditary chieftainship is

common in Polynesia, where a considerable social gulf may exist between nobles and commoners.

Initiation.—Ceremonies of initiation into manhood occur amongst Australians and many Papuans, and are found amongst some Melaneseans, mainly in connection with secret societies (*q.v.*), which in some cases dominate the social organization.

Religion.—The belief in spirits of the dead is general throughout this area, and some degree of cult of the dead is present everywhere. In some cases, mortuary ceremonial reaches a very high degree of elaboration, particularly in the case of chiefs. Violent orgies of mutilation on the occasion of a death are reported from Australia, and in extreme form from Polynesia. But the existence of an elaborate mortuary ceremonial is not necessarily associated with anything that can be called a worship of the dead, which is probably confined to Polynesia, parts of Melanesia and Micronesia. Between spirits of the dead, or ghosts, and spirits or gods not definitely associated with some ancestor, there is no sharp line of demarcation, but sometimes there are separate words for these two kinds of beings, and a different cult is associated with each, a practice common in Melanesia. Certain ghosts or spirits may be of sufficient importance to rank as gods, who are able to affect more or less the destinies of man, or who are credited with having performed certain acts of creation, or to have introduced important foods or new customs. An elaborate mythology centres around these culture heroes throughout the area, and provide us with suggestive hints as to culture movements and culture contacts in the past.

There is, perhaps, more uniformity throughout the area in the realm of magic (*q.v.*) than in that of religion, in so far as it is possible to separate the two, for there is a transparent sympathetic basis of almost all the magical practices. In addition to direct sympathetic magic without the aid of ghosts or spirits, we also find, particularly in Melanesia, the coercion of both ghosts and spirits for the attainment of what are usually anti-social ends. Divination of sorcerers is also common, which, together with fantastic beliefs concerning the powers of sorcery, accounts for a good deal of the strain to which social relations between individuals, and between groups is subjected in this part of the world. One of the commonest causes of murder is revenge for supposed sorcery.

BIBLIOGRAPHY.—The separate articles, AUSTRALIA, etc., should be consulted for the bibliography of this region. For the racial history, see A. C. Haddon, *The Races of Man* (Cambridge, 1924). In Sir J. G. Frazer, *The Belief in Immortality* vols. i.-iii. (London, 1913-22-24), there is a good account of the chief features of social organization and religion of the principal groups within Oceania.

(W. E. A.)

ARCHAEOLOGY

From permanent contact with European settlers in the latter part of the 18th century the transition from the Stone to the steel age was rapid. Previously writing was unknown in the area, if we except the pictographic "script," as yet imperfectly explained, of Easter Island (*q.v.*).

Although it is improbable that any of the more important monuments have entirely escaped observation and record, the greater part of the area has never been properly surveyed in an archaeological sense, and the published records available for many islands are meagre and of unequal value. The only islands of which anything like detailed surveys have been published are Easter, the Australs, the Marquesas, Hawaii (some islands), the Carolines (Ponape, and Kusaie) and, in part, New Zealand and the Chathams (see Bibliography). Surveys of Tonga, Tahiti, Necker I., Rapa-iti, and some smaller islands (Fanning, Malden, Christmas, etc.) are now in preparation by the Bishop Museum, Honolulu.

Absence of Palaeolithic Culture.—In the moist climate, perishable objects were quickly destroyed, and pottery being absent in Polynesia (except Fijian vases introduced into Tonga), the materials for archaeological study are practically limited to stone tools and monuments. No evidence of a Palaeolithic culture has been found in any part of Oceania. The prevailing tools are everywhere axes or adzes of stone (occasionally also of shell), polished wholly or in part, although flaked obsidian was also used

in certain islands where it occurred (e.g. Easter, New Zealand, New Britain), and roughly flaked quarrying tools bearing a superficial resemblance to palaeolithic hand-axes are found in Easter Island. Judged by its tools, the prehistoric culture of the area belongs entirely to the neolithic phase.

The ethnographical division into Melanesia and Polynesia holds good, in the main, for archaeology. In the former region adzes are of the "celt" type and rounded or sublenticular in section; in the latter they are predominantly straight-edged and angular in section, and further subdivided into a tanged and tangless type, characteristic of east and west Polynesia respectively. The distribution of monuments is in substantial agreement with that of the tools, and the elaborate structures of masonry characteristic of Polynesia scarcely occur west of Fiji, where the few stone monuments found are crude and megalithic in character. Exceptions in the Solomon and Banks islands may be regarded as relics of Polynesian migrations eastwards, or as due to later reflex movements.

Absence of Stratified Sites.—No stratified sites showing culture sequence, except in a minor degree in New Zealand, have been found. The habit of making funerary offerings seems to have been little developed, and grave-goods, where discovered, do not differ markedly from artifacts of recent date. Only in parts of Melanesia has the occurrence of deposits distinct in character from the products of the historic inhabitants been observed.

POLYNESIA

In Polynesia there is at present little archaeological evidence of a succession of cultures; monuments and implements represent at most an earlier and, in some cases, a higher phase of the culture that continued into historic times. Exceptions do occur, however; adzes of distinctively Melanesian type, found in Tahiti, and the carvings of bird-headed men in Easter Island suggest the possibility of a pre-Polynesian occupation of parts of eastern Oceania by the negroid race. The evidence is too scanty to be entirely convincing, and the presence of a strong negroid strain in the inhabitants of eastern Polynesia is more probably due to racial intermixture during the Polynesian migrations through Melanesia than to a fusion in the islands in which it is found.

Eastern Polynesia.—In all the island groups east of Tonga and Samoa, without a single important exception, occur the remains, now more or less ruined, of megalithic structures, the sacred places or *marae* of the Polynesians. These consist typically of paved rectangular enclosures, surrounded by stone walls, and containing one or more rectangular stone platforms, sometimes, as in Tahiti, of stepped pyramidal form. The elements were variously combined, and differ in details of construction, contour and size. Thus in the Marquesas the walls are low or absent, in the Australs the platforms are generally lacking, while in Tahiti and Hawaii all features are generally present. The platforms were faced with large boulders or hewn blocks of stone or coral, sometimes weighing many tons, and often neatly fitted in regular courses, although mortar was never employed. The core consisted of earth or rubble, and sometimes contained burial pits or vaults. Platforms served also as substructures for sacred houses built of perishable material, for the exposure of the dead, as sacrificial altars, etc.; and the question whether they were intended primarily as tombs has yet to be settled by excavation. Many of them were originally surmounted by large figures of wood or stone in conventionalized human form. Such stone figures, some still *in situ*, are found in Hawaii (Necker), Easter Island, Pitcairn, Tahiti, and the Australs (Raivavai), and in the Marquesas, where they exactly resemble those carved in wood. In the Marquesas, platforms, which always had vertical sides, were also much used for secular purposes, both in public assembly places (*tohua*) as seats for the spectators of dances, and as foundations for the ordinary dwelling-houses. The extreme development of terraces and platforms in the latter islands is due to the scarcity of level ground in the steep and narrow valleys, and to the abundance of suitably shaped boulders and easily worked volcanic stone. The largest recorded platform, that of Oborea, in Tahiti, now almost destroyed, measured 90 by 29 yd. at the base, and rose in 10 or 11 steps to a height of about 50 ft.;

but in general these structures did not exceed 12 ft. in height. The antiquity of particular structures cannot be determined from internal evidence, but they were presumably built by ancestors of the historical Polynesians, who on traditional evidence did not reach the area earlier than the 7th century A.D. The fact that they occur in similar form in all groups, including Tahiti and Hawaii, which remained without intercommunication after the great voyages of the 13th and 14th centuries, as well as on intermediate islands, afterwards uninhabited, like Malden and Fanning, shows that the type must have been fully developed by the time of these voyages. Many were still in use when discovered, and some were even constructed in the historic period.

In Pitcairn island, which was uninhabited when occupied by the mutineers of the "Bounty" in 1789, are found many traces of a former Polynesian settlement. The *marae* and stone figures are said to resemble those of Easter; but a number of large stone chisels and broad-edged axes dug up in the soil are quite exceptional in type. Other small islands, uninhabited at the time of their discovery, but bearing evidence of former Polynesian settlement, include Palmerston, Flint, Malden, Christmas, Fanning, Necker (Hawaii).

Western Polynesia.—In Samoa and Tonga typical walled *marae* are not found, but in the former island there are numerous flat-topped mounds and platforms of considerable antiquity. Some of these were substructures for temples; others were used for burial. But certain earth and stone mounds of exceptionally large size, in Upolu and Savaii, appear to have been constructed for defensive purposes. One of these, near Apia, measures approximately 100 yd. square at the base and is 35 ft. high; it is traditionally supposed to have served as a platform for the houses of Tongan chiefs. In the mountainous interior of Upolu (Samoa) is a group of upright basalt slabs on a paved floor (*O Le Fale-o-le-Fe'e*), evidently the supports of a former house or temple, while in Savaii there are remains of roads and raised causeways elaborately engineered but long disused, and partly destroyed by an overflow of lava.

The most striking example of a true megalithic monument is the trilithon (Haamonga) on Tongatabu; it consists of two uprights and a lintel stone mortised into them, 15 ft. high, and is stated by tradition to have been erected in the 13th century by Tui-ta-Tui in connection with a Kava feast. Not far distant are a large upright slab and two stone-faced house platforms. On the north coast of Tongatabu are the equally remarkable "tombs of the kings" (*Iungi*), formerly reserved for the burial of sacred chiefs called "Tootongas"; these are stepped or terraced platforms containing burial vaults and are faced with hewn coral blocks measuring up to 22 ft. in length. The earliest of these also probably date from the 13th century, but the construction of similar tombs continued down to the middle of the 19th century. Some of them are merely enclosures of rough stones.

Stone fortifications occur on many islands, and reach their highest development in the terraced entrenchments and solid stone towers on the mountains of Rapa-iti. Of the petroglyphs, representing stylized human and animal figures, concentric circles, etc., which are found abundantly in Hawaii and the Marquesas, some by their situation seem to have had religious significance, while others are only "travellers' marks"; many are of recent date.

New Zealand and Chatham Islands.—The final settlement of New Zealand by Polynesian immigrants from Rarotonga in the 14th century was preceded by an earlier branch of the same race, possibly also by people of Melanesian affinities, though this is disputed. Archaeology throws little light on this question, except in so far as no adzes of Melanesian type have been found in the older deposits. Only one properly stratified site has been excavated, viz.: Moa-bone Point Cave, near Christchurch, Otago, where the remains found in the lowest stratum prove the early inhabitants to have hunted the extinct moa. Although accurate dating is impossible, considerable antiquity is suggested by the fact that the coast has sunk several feet since the deposits were formed. The rock-paintings and the implements, which include knives, saws, drills, spear-points and finely "retouched" scrapers, of quartzite, obsidian, chalcedony and chert, indicate that the cul-

ture of the moa-hunters did not differ essentially, except in its higher standard of craftsmanship, from that of the historical Otago Maori.

The earthwork and stone fortifications belong for the most part to Maori (*q.v.*) culture, as do probably the pit dwellings and terraces of the Pelorus and Auckland districts and the artificial caves and figures carved in the soft tuff of Rotorua. Curious figures incised in a sandstone pit in Auckland and rock-carvings in the Kaingaroa plains representing canoes of modified Maori type are among the more interesting recent discoveries. The Chatham Islands appear to have been colonized by pure Polynesians, the extinct Moriori (*q.v.*), coming from the South island of New Zealand in about the 12th century. Their stone implements resemble Maori types, with the exception of tanged obsidian blades; tree-carvings and much weathered bird figures incised on cliffs have been reported.

MICRONESIA

The most important monuments of Micronesia are found in the Caroline islands, where both on Ponape and Kusaie extensive groups of buildings intersected by canals were constructed on artificially enlarged reefs protected by sea-walls. They take the form of rectangular paved courtyards, frequently in contiguous clusters, constructed by laying natural columnar blocks of basalt lengthwise and crosswise in alternate layers. These walls rise in places to a height of more than 20 ft., but were not roofed. The enclosures formerly contained houses of perishable material, traces of which remain; also platforms, terraced or pyramidal, in which were sepulchral vaults roofed with coral or basalt slabs. The most striking and best preserved of these structures is the royal cemetery of Nan Tauach at Matolenim (Ponape), which stands in a double enclosure and contains four burial chambers. Enclosed burial platforms of a somewhat similar type occur farther west in Yap and the Bunaj islands. They have certain elements in common with the *marae* of Polynesia, to which they are possibly related either directly or as collateral branches from the same cultural stem. Although the date at which these "sacred cities" of the Carolines were begun is not clear, they were still inhabited at the time of their discovery, and the tradition of how they were constructed by means of inclined planes of tree trunks survives. The stone pounders, and shell and other objects found in the tombs, do not suggest a high antiquity.

In several of the Marianne islands occur groups of conical pillars called *Latte*, of square-cut coral, surmounted by large hemispherical capitals, and constructed either of monoliths or layers of coral cemented together. These are always arranged regularly in two parallel rows, and the most probable explanation is that they were supports for the floors of raised temples or houses, since destroyed. Remains of a burial have been found in a cavity in one of the capitals, but this was presumably only a secondary usage. The largest, in Tinian, are 15 ft. in height with capitals 6 or 7 ft. in diameter; those of Guam and other islands are much smaller. Associated with these monuments, and suggestive of some ceremonial purpose, are remains of burials, pottery, stone mortars and other artifacts.

MELANESIA

In various parts of Melanesia, from New Guinea to Fiji, are found relics of a prehistoric culture or cultures, which cannot as yet be dated or correlated satisfactorily. An important region covers the east end of New Guinea, New Britain and the adjacent archipelago, where the remains found include ornamented pottery (somewhat similar to that of prehistoric Japan), engraved skulls, obsidian implements and stone pestles and mortars, some of which occur at a considerable depth in river gravels and all of which are quite distinct from the products of recent inhabitants. In the same region, but within a more limited area, are low stone circles, lines and heaps of stones, now used as squatting places and, in part at least, of recent origin. Rock paintings and engravings are numerous in the district behind Port Moresby, some of them coated with a film of calcium carbonate, indicating a certain antiquity. Megaliths are widely distributed and irrigation terraces are found throughout Melanesia. In the Solomon islands (Bou-

gainville and San Cristoval) upright stones occur singly and in groups; in San Cristoval some villages are bordered with stone walls or platforms, and numerous stone-faced and earth mounds, containing shafts leading to burial chambers, and sometimes surmounted by stone statues, small dolmens or upright stones, are still in use. They may be related to Polynesian burial platforms. Their form and the mortuary customs associated with them have led to a comparison with early Egyptian mastabas; attention has also been called to a supposed resemblance of certain pig-tail figures to Egyptian royal statues, but this seems too remote to justify the emphasis laid upon it by some authorities. In the New Hebrides the antiquities include menhirs, stone sacrificial "tables" or dolmens, walls and high platforms, and obsolete types of pottery ornamented in a great variety of styles. There is an exceptional development of stone walls and buildings in the Banks islands, some, however, of recent construction. In general, chronological evidence is almost entirely lacking for these monuments, and the difficulties of distinguishing between ancient and modern are increased by the fact that parts of Melanesia are still living in a "megalithic period." In New Caledonia stone statues (in caves in Lifu) and a few "dolmens or trilithons" have been reported. Petroglyphs are common to all these groups, and particularly numerous in New Caledonia, where they take the form of human and animal figures, spirals and other patterns. Some of the better structures may be attributed either to late waves of Indonesian immigrants, or to reflex Polynesian influence, which has affected many of these islands in comparatively recent times; the *nanga* of Fiji so closely resemble Polynesian *marae* as to leave no doubt of their common origin.

Migrations and Hypotheses.—There is general agreement, on the evidence of oral traditions supported by physical, linguistic and botanical evidence, that the ancestors of the Polynesians—a composite stock including Caucasian, Mongolian and Negroid elements—must have come originally in a series of migratory waves from the Asiatic continent. Their starting-point cannot be definitely fixed; hypotheses vary as between India (Ganges or Chota Nagpur), Assam, and the Cambodia-Siam region of Indo-China. In favour of the latter view is the fact that a people speaking an allied language (Mon-Khmer) and having physical affinities with the Polynesians is still living there. They had probably settled in the Indonesian archipelago by the latter part of the first millennium B.C., whence they proceeded in at least two main streams of migration by way of Melanesia or Micronesia to Fiji, which they reached in about the 5th century A.D. Thence eastern Polynesia and New Zealand were settled in successive voyages during the 7th to 14th centuries. Hawaii seems to have been reached first by a direct migration from Indonesia and subsequently by a branch of the main wave from south-eastern Polynesia; this conclusion is supported by archaeological study which recognizes two distinct types of *heiau* (*marae*), the later of which corresponds more closely with the Tahiti-Marquesas type.
